ON WRY NECK,

RESULTING FROM

CARIES OF THE CERVICAL VERTEBRÆ,

BY

WILLIAM A. ELLIOTT, F.R.C.S.I.,

SURGEON TO THE WHITWORTH HOSPITAL, DRUMCONDRA.

FROM the number of cases of this formidable disease which have been brought under my observation, I have selected the following, as it represents the affection in a very aggravated form—the treatment of which, and its results, I consider interesting, and of some practical importance:—

Margaret Lynch, ætät 7 years, was admitted into the Whitworth Hospital, Drumcondra, on the 29th April, 1856. The child, who was badly nourished and emaciated, presented the following appearances:—The head (as exhibited in figure No. 1) had fallen completely to the left side, with an inclination forwards; the right side of the face was turned upwards, and was much congested from impeded circulation; the cheek rested upon the left side of the chest, and advanced so far downwards and forwards as to reach within about two inches of the nipple; the chin had passed the mesial line of the thorax, and advanced as far as the junction of the middle with the sternal third of the right clavicle.

FIG. 1.

The posterior aspect of the patient (which is represented in figure No. 2) exhibits the head, as thrown to the left side and resting upon the top of the shoulder. The spinal curvature, with its convexity looking towards the right side, occupied the entire of the cervical region; although, to the best of my judgment, I could only localise the disease as existing in the 3rd, 4th, and 5th cervical vertebrae.

The following history of this case was given by the patient's mother:—When about the age of 6 years, whilst playing roughly with her sister, the child received a very severe twist in the neck, which was immediately followed by faintness; and afterwards she complained of stiffness and pain in the part—the pain being greatly increased upon the slightest movement of the head or neck.

Immediately after the receipt of the injury the child was placed under surgical treatment, but her health, which, previous to the accident, was represented as having been very good, gradually declined.

FIG. 2.

For the next nine months, during which the most judicious treatment was unremittingly pursued, she suffered, at intervals of about three months, from inflammatory attacks, each being followed by a more gradual inclination of the head and neck to the left side.

The principal symptom which she complained of was a constant aching pain in the upper part of the neck, which was increased by making pressure upon the vertæx and along the spinous processes, but greatly aggravated by the slightest attempt to rotate the head and neck.

In the recumbent posture she seemed to rest with comparative ease; but, when asked to sit up, the effort was made by first firmly grasping the head with both the hands, and then the act was accomplished with no small amount of difficulty.

In the erect posture the child rested her head upon the left shoulder; but, when desired to raise the head, she could only do so to a very trifling extent—say to half an inch or three quarters; and this position could only be maintained for a few seconds.

When asked to walk, she instinctively raised the top of the shoulder and placed it against the ear and side of the head. An amount of support was thus afforded, which enabled her to move slowly and cautiously about.

The treatment which I adopted in this case consisted of Constitutional, Local, and Mechanical agents, viz.:—She was ordered full and generous diet; iron combined with quinine, varying at intervals with other tonics, and cod-liver oil at night.

Counter irritation was constantly kept up in the neighbourhood of the diseased vertebrae, by means of small Blisters; alternating, when the parts were healed, with applications of the Tinct. Iodine.

The child was strictly kept to her bed, with the head and shoulders slightly elevated. This course was steadily pursued for six weeks, when a visible improvement had taken place in her general health, accompanied with almost complete subsidence of pain in the neck.

The case having thus far satisfactorily progressed, and fortunately without any formation of abscess, I ventured upon the gradual restoration of the head and neck to their normal positions, by adopting the following means:—

I placed a soft but firm pad, three quarters of an inch in thickness, between the maxilla and chest (which was the maximum extent to which the parts admitted of separation). This pad was very gradually increased in thickness, until the head became so far elevated as to permit a collar made of leather, one inch in height, to be so applied

as to encircle the entire neck, which was worn by day and night.

The child became accustomed to the use of this support after three or four days, when I allowed her to get up and walk about the ward. Of this permission she gladly availed herself, and seemed to derive much comfort from the collar, which was raised from time to time at the left side and under the chin, by means of strips of thick chamois leather, pasted one over the other upon the upper edge of the collar, until the head and neck were brought to the position represented in figure No. 3.

FIG. 3.

The head and neck having been restored to their normal positions, and the child's health being much improved, I gave permission for her removal from the Hospital at the latter end of December, 1856 (being eight months from the period of her admission), with directions to have the collar kept constantly on.

In three weeks after patient's discharge from hospital she presented herself at the dispensary, when I was disappointed at finding her general health very much impaired; she seemed weak and languid, and had become much thinner. Her constitution had suffered considerably from want of care and suitable nourishment, with which her parents were, in all likelihood, unable to supply her. She was, therefore, re-admitted on the 15th January, 1857, and kept in hospital until the 20th of June following, when she was discharged cured.

I have had frequent opportunities of seeing Margaret Lynch since the above date. In October last I examined her and made the following notes of her case:—

This little girl is much altered in appearance, she has grown strong, her figure well developed, and her general health good. There is some amount of rigidity in the neck, accompanied by deep-seated thickening of parts commencing from about the third to the fifth or sixth vertebra, which indicates that anchylosis to a greater or less extent has taken place, with some apparent shortening of the neck.

The motions of the head and neck are in a very trifling degree impeded, she can fully bend the head forwards. Lateral inclination at both sides is in some measure limited, she can throw the head sufficiently backwards, as to enable her to look almost fully and freely upwards without any compensatory movements in the dorsal or lumbar regions. I may fairly say, however, that close observation is requisite to detect any existing difference from the normal motions of the cervical region.

The cases which, in my experience, have been successfully treated according to the foregoing system have occurred in children between the ages of three and ten years. In whom I found the head and neck thrown into various positions—viz., laterally and forwards with torsion of the

neck. Laterally, with different degrees of inclination. Forwards with the chin resting upon the sternum, and Backwards with convexity of the spine anteriorly. This latter form of the disease I have found much more intractable in its management than any of the former.

In each case of recovery no symptomatic abscess existed. I have attempted this mode of treatment even in patients who were suffering from purulent discharges, but soon desisted, finding that all such interference was fruitless, and productive rather of evil than good results. They were, however, persons of eminently strumous diathesis, and consequently unpromising subjects for any mode of treatment.

We cannot expect that each case of recovery can be perfect, and unaccompanied with either more or less of deviation from the normal formation of the neck. In Margaret Lynch's case the disease occurred in an extremely aggravated form; and, although her recovery was unattended with deformity, other patients with less formidable symptoms have recovered with slight malposition of the neck, evidently resulting from absorption of bone, and possibly of intervertebral substances.

I attended with the late Dr. Cusack and Sir Henry Marsh a young lady, aged 23 years, of extremely weak and delicate constitution, in whose case there existed but very little deviation of the spine and unaccompanied with abscess. She had all the well-marked symptoms of cervical caries; after eighteen months from the first appearance of the disease, she died. Three weeks previous to her death she complained for the first time of difficulty in deglutition accompanied by loss of power over the hands and arms, which quickly extended to the trunk and lower extremities, and terminated in total paralysis. Her miseries were greatly aggravated by loss of control over the sphincters of the bladder and rectum.

We find it difficult in spinal caries to define the exact extent of the disease, and what structure has been the primary seat of inflammatory action. It may have its origin in the intervertebral substance, or in the cancellous tissue of the vertebræ, which latter may be considered the strumous form of the disease, and most likely to be followed by the formation of matter. But as the disease advances both structures may become implicated.

The direction towards which the head and neck will become inclined (should the disease not be arrested) will be determined by that part in which the morbid action exists. To this situation the head will invariably be found to lean.

It may be suggested, and it occurred to my mind at first, the prudence of interfering by mechanical means in restoring the shape of the part, by raising the head and neck, and thus keeping apart the inflamed and ulcerated surfaces of bone and intervertebral substance. Such interference might seem a positive obstacle to the formation of anchylosis, and somewhat at variance with the opinions of systematic writers upon this subject. Yet experience justifies me in stating, that whilst the curative process of anchylosis is progressing, the restoration of parts to their normal position may contemporaneously be conducted with the utmost safety and benefit to the patient.

When caries occurs in any part of the spinal column, it is invariably accompanied by a debilitated condition of the general system; therefore, it is manifestly important to attend strictly to hygienic treatment, if we hope for successful results.

In caries and other affections of the neck attended with contraction, I have practically experienced the great utility of the leather collar, to which I have already alluded. It forms an important mechanical adjunct in our treatment. When properly shaped, the lower edge should be made to rest upon the sternum and clavicles, whilst the upper edge should with equal accuracy be adjusted and brought in contact with the inferior maxilla and occiput.

The indications fulfilled by this support are obvious—viz.: 1st. Having fixed points for the collar to rest upon, the

superincumbent weight of the head is thereby in a great degree removed from the inflamed and diseased tissues.

2nd. Mobility of the parts is rendered greatly limited.

3rd. The collar affords an amount of passive resistance to the action of the cervical muscles, the contraction of which must be attended by a closer approximation of the diseased and softened surfaces, thereby promoting a more rapid absorption of bone and intervertebral substance.

4th. There is no necessity for constant confinement in the recumbent posture. When the collar has been applied, patients may be allowed occasionally to walk about and enjoy open air exercise, which is not the least important advantage to be derived from the mode of treatment which I have suggested.

A CASE
ILLUSTRATING A RARE FORM OF
RHEUMATIC PERICARDITIS,

SUCCESSFULLY TREATED.

By ROBERT HUNTER SEMPLE, M.D., M.R.C.P.Lond.,
SENIOR PHYSICIAN TO THE ST. PANCRAS AND NORTHERN
DISPENSARY, LONDON, PHYSICIAN TO THE STANDARD LIFE
ASSURANCE SOCIETY, ETC.

THE following case is an instance of a very severe form of pericarditis, having its origin, no doubt, in a rheumatic diathesis, but not preceded, nor accompanied, nor followed by the ordinary characters of rheumatic fever. It would appear that the rheumatic poison circulating in the system concentrated itself almost in the first instance upon the heart, thus rendering the premonitory symptoms very obscure and the disease itself doubly dangerous.

Mr. —, a gentleman, aged 32, tall, and of robust appearance, of an active and energetic disposition, engaged in an extensive mercantile business and accustomed to generous living, but not amounting to excess, became affected about the end of June last year with several anomalous symptoms. He was occasionally feverish, restless at night, disinclined to food, but rather thirsty, and his mind was somewhat affected at intervals, especially at night. These symptoms, however, assumed a kind of intermittent character, for on some days he could go to town and transact his ordinary business, while on other days he would remain at home and lie in bed the greater part of the day. He was perfectly rational when spoken to by his medical attendants, and the wandering showed itself chiefly to some members of his own family.

On Saturday, June 24th, I was attending a member of his family at a little distance in the country, and I came to town with him; he was then quite rational, and apparently in good health, and I left him in the west-end of London. On Sunday, when I went to visit the other patient, he was in bed, and I examined him carefully in conjunction with his ordinary medical attendant. We could find nothing definite in his symptoms, which somewhat resembled those of incipient typhoid fever, which indeed was then prevailing, not only in the neighbourhood, but in the house itself; but I felt sure that he was not labouring under this disease, because I had attended him some years before in a well-marked attack of this very fever, and I thought it very improbable that he would take it a second time. There were no symptoms of typhus, the pulse was rather rapid, the head was warm but not hot, the skin was moist, there was no eruption, there was some thirst, and he was quite rational. We, therefore, recommended rest, and a little saline medicine, and a moderate amount of supporting diet. The next day (Monday) I saw him incidentally in the evening as I was seeing the other patient. He was then in much the same condition; and on Tuesday I saw him again, when he was in bed, but quite tranquil, and apparently getting better; and I left him under the care of his usual medical attendant. I did not see him again until July 5th, when I received a telegraphic message from his wife to go down and visit him at Broadstairs. This message was sent to

me without his knowledge, and was caused by his restless and excited manner, want of sleep, and frequent incoherence of mind, but there were not any other remarkable symptoms. On visiting him I found him quite tranquil, but rather low-spirited; he was sitting up, and was quite able to walk about. As he did not admit that he was ill, I had some little difficulty in making a careful medical examination, but I found that the head was not hot, the skin was cool and moist, and the pupils acted normally; the pulse was rather quick, but soft. All I could ascertain was that he had had very restless nights, with a total want of sleep, and great incoherence. It should be mentioned that since I saw him at home he had been actively engaged in various pursuits, and had indeed been making rather violent efforts to "shake off" the complaint, and had come down to Broadstairs by himself, not only without any advice, but rather in opposition to it. As his condition was unsatisfactory and the symptoms were anomalous, I determined not to leave him for the night, and as he was labouring under evident excitement and irritability of the nervous system, I ordered him to take half a drachm of Battley's sedative solution at bed-time, and the dose to be repeated if necessary, requesting that I might be called during the night in case of his being restless. I was called accordingly, and found that the opiate had produced no effect at all, and I therefore repeated the dose, and recommended more to be given afterwards. After taking about two drachms of the opiate, no effect was produced, and the night was passed, I believe, absolutely without sleep. As I thought that the Battley might possibly not be genuine, I now changed it for the hydrochlorate of morphia, of which I gave, in solution, a quantity amounting to half a grain, but still no sedative effect was produced. I remained with the patient the greater part of the day of July 6th, and gave him additional doses of the hydrochlorate, one-third of a grain at a time, but still no benefit ensued. I was obliged to return to London, but directed that the morphia should be continued, and that a local practitioner should be called in. The next day I received a note from the patient, perfectly well written, but of a somewhat peculiar character, and seeming to express some annoyance at my having been sent for to visit him, and he made no allusion to his being ill. For the next few days I heard nothing of him, except that I was informed, in conversation with some of his relatives, that a local practitioner had been called in, and that "gout" had developed itself in one of his feet. I was rejoiced to hear this statement, as I now thought that a clue was given to the nature of the affection. It should be mentioned that the patient had never suffered from rheumatic fever.

On Monday, July 10, I was summoned by a telegraphic message to go down immediately to Broadstairs, as the patient was much worse, and the medical gentleman in attendance wished to meet me in consultation. I accordingly went down and met Mr. Walter of the above town, and I desire to express my sense of that gentleman's extreme care and ceaseless attention throughout the progress of the case. My first inquiry on seeing the patient was, whether there was any pain or swelling of the feet, and I found a slight redness on the left great toe and some tenderness on pressure; but these symptoms were quite transient, and an hour or two afterwards I could not detect them. But in other respects the patient was very dangerously ill. He was lying prostrate in bed, breathing rapidly and laboriously, with a quick, rather small and intermittent pulse, head moist, pupils acting normally. On examining the region of the heart, I found that the præcordial dulness was increased, particularly upwards, while the impulse and sounds of the heart were quite imperceptible. It was now evident that there was pericardial inflammation with effusion into the sac of the pericardium. I, therefore, in consultation with Mr. Walter, directed a large blister to be laid over the præcordial region, and at the same time strong blistering fluid was applied to the feet and toes. The solution of morphia (which had been

continued at frequent intervals ever since I first ordered it), was directed to be still given, and brandy was administered in the dose of a tablespoonful every two or three hours, together with strong beef-tea and milk. The objects aimed at in this treatment were—first, to support the strength of the system and to stimulate the flagging action of the heart; secondly, to divert the effusion of serum or lymph from the surface of the heart; thirdly, to produce a kind of artificial rheumatism in the extremities; and, fourthly, to tranquillize the nervous system while the process of repair was going on in the pericardium. I considered that depletory measures were unadvisable, and that no benefit could be expected from mercury in any form. As the patient's case was very critical, I remained with him all night, and repeated my visits from London from time to time, often staying near him at night.

The above treatment did not produce any immediately beneficial effects; but the blisters answered the purpose of causing rather extensive vesication over the chest and over the feet and toes, but without much pain. Nothing like rheumatism or gout was developed, either then or afterwards; but after a day or two the action of the heart became perceptible, both to the touch and by the stethoscope, although its impulse was still weak, the sounds were feeble, and there was no murmur. The patient was quite delirious, but not violently so, his thoughts wandering chiefly about matters of business; his head was always cool and moist to the touch; the pupils were quite regular, and acted on the stimulus of light; the bowels were moderately open; the urine was passed freely; there was abundance of acid perspiration. It should be mentioned that the urine was examined, but it contained no sugar or albumen, nor did it appear thick or high-coloured.

Thus matters went on for some days, the breathing being rapid and laborious, 40 to 50 in a minute, the pulse rapid and intermittent, so that it could hardly be counted; but it appeared to be about 160, and the unconsciousness and delirium continued. There was, indeed, very little favourable about the case, except that the patient continued to live and to take support and stimulants, which were given very freely, and the acetate of morphia was regularly administered in the dose of a third of a grain to half a grain every three hours. Notwithstanding this enormous quantity of morphia, the pupils were unaffected, and very little genuine sleep was procured.

It was now thought advisable that another London opinion should be requested in consultation, owing to the extreme gravity of the symptoms, and accordingly I went down in company with a distinguished hospital physician on the 19th of July. On relating to him while on the journey the features of the case, he informed me that he had seen two cases, and only two, as far as I understood him, of a similar kind. We found the patient nearly in the same state as that I have just described, but the inflammation had now spread to both lungs, and there was pleuro-pneumonia on both sides; the action of the heart was still weak, but it was perceptible, and there was a distinct but not very loud friction sound. The opinion of the other physician, both as to the nature of the disease and the treatment to be pursued, coincided entirely with my own, and no change whatever was recommended. Brandy was to be regularly given in the dose of a tablespoonful every two hours, or more if necessary; milk and strong beef-tea, or jelly, or turtle-soup, were to be taken as freely as possible, and the morphia was to be continued in the same doses as before until the pupils were affected.

Still no great change was observed, and it became obvious that the case would run on for the same length of time as one of ordinary rheumatic fever, if the patient survived the heart-affection, and this turned out to be the fact, for when I saw him on the 5th of August, which was about five weeks from the commencement of the attack, he was beginning to get a little better, and was becoming rational. Still the pulse was very rapid, weak, and intermittent; the breath very quick and laborious, and there was extensive dulness all over the posterior part of the lungs, with fric-

tion sound and tubular breathing; the action of the heart was now distinctly perceptible, with occasional friction sound, but I could never detect any endocardial murmur. There was profuse perspiration and a miliary eruption over the skin. A rather alarming symptom presented itself about this time—namely, swelling, tenderness, and redness along the course of the right basilic vein, and I was under some apprehension that thrombosis or embolism might develop itself; but by assiduous fomentation of the inflamed vein, the pain and tenderness gradually subsided and gave no further trouble. As the general symptoms were now relieved, the quantity of brandy was reduced, but the use of the morphia was still continued, though in somewhat smaller doses, and at rather more distant intervals. I last saw the patient at Broadstairs on the 12th, 13th, and 14th of August, when he was very much better, was quite rational, and was able to eat his meals as usual. He was still suffering, however, from shortness of breath, the pulse was very rapid, and he was very weak, but not much reduced in size.

I now saw nothing more of him until the 6th of September, when I was asked to visit him in the vicinity of London. He was now able to walk, although he was still weak, and his breath was short on making any exertion. The pulse was weak, rapid, and intermittent, and the breathing rapid; there was some dulness on the back of the right lung, but I could detect no murmur or friction sound over the heart. Since that time the patient has been in Scotland, where he has been sailing, riding, and walking, and he is now in London, pursuing his business as usual.

Remarks.—The above case was one of rheumatic pericarditis, in which the affection was altogether, or almost altogether, confined to the investing membrane of the heart—for I cannot recognize the slight and transient inflammation of one toe as more than an indication, though an important one, of the true nature of the disease. The early symptoms were rather those of a cerebral than of a cardiac nature; but it is well known that in pericarditis the intellect is very often impaired, and this latter circumstance is, indeed, sometimes almost diagnostic of pericardial inflammation. The treatment throughout, it will be observed, was of a soothing and sustaining kind, no depletion having at any time been recommended. The amount of stimulants administered was very large, twelve ounces of brandy having been given in the twenty-four hours regularly, for at least three weeks, and a smaller quantity before and after that period. The amount of morphia given was also very great, one-third of a grain to half a grain having been administered at frequent intervals during the whole of the illness. What may perhaps appear astonishing to those who are unacquainted with the results of such treatment is, that no injurious effect whatever was produced, either by the alcoholic liquids or by the morphia; the delirium diminished in proportion as the alcohol was increased, and the morphia produced no constipation of the bowels, and did not even contract the pupils.

NOTES ON THE USE OF
ASTRINGENTS, STIMULANT-ASTRINGENTS,
AND CAUSTICS,
IN
AFFECTIONS OF THE EYE.

By D. ARGYLL ROBERTSON, M.D., F.R.C.S.E.,
LECTURER ON DISEASES OF THE EYE, AND SURGEON TO THE
SOUTHERN EYE DISPENSARY, EDINBURGH.

THERE are no remedies which are so much, and but too often indiscriminately, employed in diseases of the eye, as astringents, stimulant-astringents, and caustics. Under these heads are included sulphate of copper, nitrate of silver, alum, corrosive sublimate, and the active ingredients of almost all the ordinary collyria. They may conveniently be divided into the three classes I have already specified, for although many of them possess properties

enabling them to be ranked under all the three heads according to the strength of the preparation employed; yet some possess in a higher degree the one, some the other action. This division is of essential practical importance, for cases constantly occur in which the use of a stimulant-astringent application aggravates the disease, while the employment of an astringent preparation rapidly effects a cure. On the other hand, many chronic inflammatory affections yield much more rapidly to a stimulant-astringent than to a purely astringent lotion. It is almost needless to observe that the use of a caustic solution to such a tender organ as the eye is applicable only in a few special cases.

Under the term Astringents, I would reckon solutions of tannin (gr. v. ad. ʒj.), or acetate of lead (gr. i.—ij. ad. ʒj), drops of nitrate of silver (gr. ii. ad. ʒi), and infusion of tea (ʒj. ad. Oj). A remedy I have found an excellent astringent, and for which I am indebted to my friend Dr. Andrew Inglis, is the resin of the *Argemone Mexicana* (yellow thistle) dissolved in glycerine. It is, I believe, much employed by the native oculists of India. A weak ointment of the red oxide of mercury, consisting of one part of the Pharmacopœial ointment and seven of lard, well mixed, also forms a useful astringent. The class of stimulant-astringents includes solutions of sulphate of zinc (gr. i.—iii. ad. ʒj), alum (gr. iv. ad. ʒi), sulphate of copper (gr. i. ad. ʒi), corrosive sublimate (gr. i. ad. ʒvi), nitrate of silver drops (gr. x.—xx. ad. ʒi) and vinum opii, either pure or diluted, with equal parts of water.

As caustics, the solid nitrate of silver, either pure or fused along with nitrate of potass (either equal parts or two parts of the latter to one of the former), as recommended by Professor Von Graefe, and a crystal of sulphate of copper, are those most usually employed.

I have now only a few suggestions to make regarding their use. I would first remark that the employment of all the three classes of remedies should be limited almost exclusively to the most superficial affections of the eye. Thus we find them of most service in inflammatory affections of the conjunctiva. In the earlier stages of acute inflammation of that membrane, great benefit will be derived from the use of purely astringent washes, while in the chronic stages and in its chronic inflammatory affections the stimulant-astringents are more particularly indicated. In the common affection, granular lids, it is advisable to vary the application according to the nature of the granulations; in those cases in which the granulations are large, soft, and flabby, consisting of the papillæ of the conjunctiva much distended and highly vascular, and in which the whole of the conjunctiva is congested and thickened, the use of strong astringent washes, such as those of tannin or nitrate of silver, are of most use; whereas in other cases, in which the granulations are small, hard, and light-coloured, more stimulant applications, such as a crystal of sulphate of copper, rubbed gently over the granular surface, answer best.

In affections of the cornea, astringents and stimulant-astringents must alike be used with great caution. They should never be used in acute inflammatory affections of that structure, and they must be used very cautiously, even where the inflammation is chronic and superficial, where their application is frequently of great service. If used too early or too freely, inflammatory reaction is certain to occur, and the affection aggravated. The same rule applies to ulcers of the cornea. The application of cold water is a good method of testing whether the eye is in a condition to bear the use of these remedies or not. Where its application is grateful to the patient, the use of mild astringent washes will generally be found to answer well. I may here repeat a caution, which is to be found in all ophthalmic works, to avoid the use of bad washes in ulcers of the cornea, as the chloride of lead, which is formed by the union of the wash with the lachrymal secretion, becoming deposited at the foot of the ulcers, forms a permanent opacity. To hasten the absorption of corneal opacities, a weak stimulant-astringent wash may be freely used.

Stimulant-astringents and astringents should never be employed in iritis, or any of the deeper seated inflammations of the eye; as, so far from doing any good, they invariably aggravate the disease. In fact, the worst cases of iritis a surgeon can be called upon to treat, are those in which such lotions have been employed in the earlier stages.

Caustic applications are not required in many affections of the eye. I have already referred to the use of sulphate of copper in one variety of granular lids. They may also be employed in chronic enlargement of the caruncle—in eversion of the lids from inflammatory thickening of the conjunctiva, and to remove the fungoid growth which often forms at the conjunctival wound after the operation for strabismus; but in most of these cases the knife or scissors are to be preferred. In a case of chronic fistula of the cornea, I found the application of a fine point of the solid nitrate of silver induce closure of the aperture. Caustics are occasionally employed in prolapsed iris to remove the prolapsed portion of the iris. It is a highly dangerous practice, as the amount of irritation thus set up is very apt to give rise to suppurative inflammation of the iris and its consequences. The use of the scissors is attended with far less risk, and better results.

These jottings are the results of experience and observation, and, I trust, may prove serviceable in leading to a correct use of these valuable but often misapplied remedies.

CASE OF

MALIGNANT ULCERATION OF THE ŒSOPHAGUS PENETRATING THE TRACHEA.

By WILLIAM LEDWYK CROWTHER, F.R.S., M.R.C.S.E.,
SURGEON TO THE GENERAL HOSPITAL, HOBART TOWN,
TASMANIA.

GEORGE C—, aged 52 years, of robust habit and previously good state of health, applied to me on the 28th of May, 1865, having at the time symptoms of stricture of the œsophagus, the seat of obstruction being immediately behind the sterno-clavicular articulation. There was no actual impediment to the transit of liquid aliment, although a greater effort than natural was required to carry it past the affected spot, and the passage was always attended with pain. Under treatment these symptoms wore off, and in the course of ten days he was enabled to swallow solid food without embarrassment, and on the 7th of June reported himself well.

On the 7th of July I was requested to see him, and found him coughing violently, the matter ejected being a bloody frothy mucus. The cough commenced at eleven a.m., and had continued without intermission until the time of my visit (three p.m.) Upon examination, the chest was found to be resonant throughout, and no symptoms of bronchial or pulmonary lesion were present, nor was there any cardiac disease. In consequence of the severity of the cough, the state of the larynx at that moment could not be determined with accuracy. When an attempt was made to swallow a small quantity of liquid, a violent paroxysm of coughing instantly followed, the material having evidently found its way into the air-passages. Each subsequent attempt produced a similar result, and it was found necessary to abandon the idea of conveying anything to the stomach by the ordinary process of deglutition. Upon the following day the cough subsided, and so long as aliment of all kinds was withheld, no inconvenience was experienced, nor did the circulation exhibit any disturbance. The larynx was examined, and proved to be in a healthy condition. For several days nourishment was administered by means of the stomach pump and broth enemata, but the transit of the œsophageal tube produced so much distress that at the urgent request of the patient the plan was abandoned. He sank on the 20th, thirteen days after perforation of the trachea took

place; the respiratory functions (so long as nothing was swallowed) having remained, with the exception of the first day, comparatively undisturbed.

Post-mortem examination.—The anterior wall of the œsophagus, opposite the upper part of the trachea, was extensively ulcerated, and completely adherent to the trachea. Between the two tubes a free communication had been formed by a ragged ulcerated opening, one inch and a quarter in length and half an inch in width. The larynx, as well as the trachea and œsophagus, below the immediate seat of the disease, were healthy, as were the bronchi and pulmonary tissues. On microscopic examination, the diseased tissues presented the characteristic structure of epithelial cancer.

The preparation has been presented to the Museum of the Royal College of Surgeons of England.

LECTURES

ON THE

NATURE, CAUSES, AND TREATMENT OF DYSPEPSIA,

Delivered at the

QUEEN'S HOSPITAL, BIRMINGHAM,

By BALTHAZAR W. FOSTER, M.D., F.L.S.,

MEMBER OF THE ROYAL COLLEGE OF PHYSICIANS, LONDON; LICENTIATE OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND; PHYSICIAN TO THE QUEEN'S HOSPITAL AND PROFESSOR OF CLINICAL MEDICINE IN QUEEN'S COLLEGE, AND OF THERAPEUTICS AND MATERIA MEDICA IN SYDENHAM COLLEGE, BIRMINGHAM.

LECTURE I.

GENTLEMEN,—I have long promised to deliver to you some few lectures on the various disorders of the digestive system commonly classed together under the term Dyspepsia, and I do so with the greater pleasure as I am sure that any attention you may now give to the observation of these affections will be of almost daily use to you in your after life. One of the great errors committed by students when pursuing their curriculum at the hospitals is the neglect with which they treat the more ordinary forms of disease. The bed of a patient suffering from some *interesting* complaint is too often surrounded by many observers, who would be doing far better work for themselves by carefully attending to the more common manifestations of disease to be seen in the out-patient departments of the hospital. For I would have you ponder this fact in your minds, that while you will seldom meet in your future practice with such cases as you now best love to dwell upon, your daily task will be, on the contrary, to treat, and your future success will mainly depend upon your skill in treating maladies that are now passed by as uninteresting and trivial. Far be it from me by these remarks to deter you from devoting much of your attention to the fascinating problems that medicine so freely offers for solution, and the investigation of which will in future become to the true student amid the daily routine of practice one of the chief charms of his profession. To these questions I would have you give the most careful and prolonged observation, but only when by a minute and accurate study of the more frequent varieties of disease, you have strengthened yourselves for the task. Most of the examples by which I shall illustrate these lectures are to be found among our out-patients, and by thus directing your attention to a field much neglected, yet teeming with material useful and most instructive, many of you will, I hope, enter on your professional career better armed to meet its emergencies.

Diseases of the stomach are surrounded with an amount of obscurity which, although daily decreasing with the advance of physiological and pathological knowledge, still leaves much to be cleared up by the experimental medicine of the future. Our increased acquaintance of late years with the physiology of digestion has, however, given us much useful material to apply to the solution of some of the pathological conditions of the digestive act; but the progress made has been small when compared with the growth of our knowledge in some other departments of medicine. There are several difficulties connected with the investigation of this class of diseases which, to some extent, explain this.

In the first place, our means of obtaining physical information are much limited in gastric disorders. The stethoscope tells us in no uncertain tones the various changes that occur in the viscera of the thorax, and the products of these changes are mostly excreted in an instructive form. The microscope and chemistry also have done much to elevate from obscurity to light the diseases of such organs as the kidneys, whose secretions pass from the body unchanged. But the stomach does its work silently, and only allows its secretions to pass away when mingled with food and complicated by admixture with fluids even more complex than its own. Again, mucous membranes, as we know from the researches of the great German school of pathologists, assume, for the most part, that form of inflammation called the secretory, which leaves after death such a dearth of all traces of disease. The living membrane of the stomach on this account in very many cases, even where the malady has been of long duration, offers us no appreciable changes of structure; and, moreover, the gastric juice acting, as it does, under certain conditions on the membrane whence it is derived, often sweeps away all signs of pathological action in the more extensive post-mortem lesions which it causes. Sufferers from dyspepsia themselves too often add much to the difficulty of arriving at a fair knowledge of their cases by the reluctance with which they admit, nay, often by the energy with which they deny the real causes of their disorder. In the better fed classes you will especially find this to be the case, the effects of some well-beloved indulgence on the digestive system being often hidden with the greatest ingenuity from the scrutiny of the physician. A brief consideration of these various obstacles to a more intimate knowledge of the various changes of structure produced by disordered action renders it easy for us to understand how it is that we still must speak of the *functional diseases* of the stomach. The tendency of all modern pathology is to refer all the phenomena of disease to some antecedent lesion of structure; but in all those tissues that are devoted to the performance of special and important functions, this tendency meets with its greatest difficulties.

The functions of such organs generally depend on very delicate changes in the contained matter of cells rather than upon alterations of the cells in their entirety, and these modifications occur often under certain influences with great rapidity, and with the production of great results without leaving any sufficient traces of altered arrangement in the cell contents. Our closest investigation gives us with our present appliances but negative results; we can recognize no certain chemical change, no decided abnormality in the structure of the tissues. We are therefore obliged to consider that these conditions depend upon an abnormal functional irritation, although

many of the diseases of the digestive organs that we are now obliged to include in this definition will eventually be found to depend on changes of a nutritive or formative character in the cell elements. Many pathologists would have us consider these so-called functional derangements as altogether dependant on nerve influence, and would class them all as neurosis of either the pneumogastric or sympathetic nerves. The doctrines of the neuro-pathologists are, however, I think insufficient to explain all the conditions that we speak of under the term dyspepsia; and although I believe that in the stomach, as in all glandular apparatus, the nerves play an important part, yet I am confident that, as the progress of pathology has hitherto been to limit the power of the nervous system in the production of disease, so the future will continually discover for us well-marked structural changes, anatomical or chemical, associated with what we now term functional diseases. Dyspepsia will, therefore, mean for us in these lectures a group of diseases of the digestive organs, associated with difficult digestion as their marked and characteristic symptom, but dependant upon no definite alterations of structure that we can at present distinguish. Some of these dyspepsias we may call neuroses; others, doubtless, owe their origin to abnormal conditions of either the mucous coat and its secreting apparatus, or of the other tissues, to be recognized hereafter as formative or degenerative errors of nutrition; while an increased knowledge of animal chemistry will teach us, no doubt, that a third class are referable to chemical derangements in the economy.

It is manifestly difficult to include within the limits of an ordinary definition anything like a fair statement of a class of diseases like dyspepsias; and this difficulty is increased by our want of knowledge on this subject, for good definitions can only be found as science approaches its maturity. Nevertheless many attempts have been made, of which that of M. Guipon is perhaps the best. In a modified form I give you this definition, but I would have you, while accepting it, keep in mind the observations I have just made. Dyspepsia signifies *difficult digestion dependant on either faulty secretion or disordered enervation, or both combined*. Some would discard the use of the word entirely, but it is eminently convenient, and although we may admit with its opponents that it includes many conditions essentially different in their nature and causes, yet we must remember that all these conditions are united in their one great symptom of difficult digestion. And although a more perfect pathological knowledge may in time enable us to distinguish the elementary lesion of each variety, we should be wrong in dismissing from present use a term so convenient and expressive. From the preceding remarks you will naturally expect me to place before you for your guidance some classification of the various disorders of digestion to which I have alluded, and which I propose to consider as varieties of dyspepsia. The remainder of this lecture I shall devote to the elaboration of such an arrangement, using for that purpose the labours of my predecessors, and endeavouring, with their aid, to construct a chart for your guidance and instruction. This task is no easy one, for a classification, like a perfect definition, can only be enunciated when our knowledge of a subject is drawing near to its completion. The attempt, however, will, I trust, give you some clearer views of the malady in question, and prove useful to you, not only in diagnosis, but in treatment. If we

glance over the various arrangements of the divers forms of dyspepsia that have from time to time been advanced, we are struck by the two extremes that have characterized different schools; by the one we find all deranged conditions, functional as well as organic, of the digestive organs classed under a single head, and by the other are equally to be decried multiplication of forms so great that each symptom is made to represent an independent disease. In the first place, distinction is now generally made between the derangements of digestion that are *essential* and those that are *secondary* or *sympathetic*. Dyspepsia is said to be *essential* when it is the consequence of some abnormal condition of the digestive system itself—*secondary* or *sympathetic* when it follows diseased action in any other part of the body. As secondary dyspepsia may accompany nearly every disease, the consideration of it is manifestly foreign to our present purpose and would necessitate a review of nearly all the domain of pathology.

Essential dyspepsia will, therefore, only be considered. In natural digestion as we can recognize two chief stages, viz.—the gastric and the intestinal or enteric, so we shall primarily distinguish two forms of indigestion, the one dependant on error in the first stage, the other on abnormality of the second part of the digestive act, and we shall denominate them respectively *gastric* and *enteric dyspepsia*. This division we shall find very convenient in considering the various causes of disordered action, but we must not draw the line of differentiation too strictly, for we often find digestive derangements partaking not only of a gastric but also of an enteric character, a circumstance not at all surprising when we reflect on the intimate connexion existing between the functions of the two tracts. It is necessary, therefore, to add a class of *gastro-enteric* or mixed dyspepsias, in which diseased conditions of the stomach are associated with intestinal disorder.

The duration of the malady affords us also occasion to make a distinction between *acute* and *chronic* affections. Of acute gastric dyspepsia there are two varieties—*accidental dyspepsia* and *irritative dyspepsia* (the temporary dyspepsia of Guipon). The latter we might fairly call subacute, as it has a somewhat longer course than the ordinary acute form, accidental dyspepsia. Of chronic gastric dyspepsia, the following varieties may be enumerated—arranged as nearly as possible in the order of frequency:—

1. Flatulent.
2. Acid.
3. Gastralgic
4. Atonic.
5. Catarrhal.
6. Syncopal.

In a future lecture it will be my task to explain more fully my views of the nature of these different forms of chronic indigestion; at present I may remark that many of them have been long recognized. The syncopal variety has, however, the interest of being a recent addition of which we owe our chief knowledge to a French author. Since my attention has been more especially directed to it, I have met it with sufficient frequency and associated with such characteristic symptoms as to feel justified in retaining it in a classification.

Of enteric dyspepsias we may enumerate the same varieties of the acute form that we have mentioned in the gastric class, viz.—*accidental* and *irritative*. The

following include in my opinion the various forms of chronic enteric dyspepsia:—

1. Flatulent.
2. Enteralgic.
3. Atonic.
4. Bulimic.

For reasons that I shall have to state on a future occasion I have omitted from my list *acid intestinal dyspepsia*, and I have also classed bulimic dyspepsia as an enteric variety.

The following table will show at a glance the different forms of gastric and enteric dyspepsias, and at the same time give you some information concerning the gastro-enteric class: any further subdivision is not only a burden to the memory but an unnecessary refinement:—

	Class I. Gastric Dys- pepsia.	Class II. Enteric Dys- pepsia.	Class III. Gastro-Enteric Dyspepsia.
Acute	Accidental dys- pepsia.	Accidental dys- pepsia.	Accidental dys- pepsia.
	Irritative do. Flatulent do. Acid do.	Irritative do. Flatulent do.	Irritative do. Various combi- nations of the gastric and enteric forms
Chronic	Gastralgic do. Atonic do. Catarrhal do. Syncopeal do.	Enteralgic do. Atonic do. Bulimic do.	

CLINICAL RECORDS ILLUSTRATIVE OF THE DISEASES OF CHILDREN.

By G. STEVENSON SMITH, L.R.C.S.Ed.,
RESIDENT MEDICAL OFFICER, ROYAL HOSPITAL FOR SICK
CHILDREN, EDINBURGH.

POST-SCARLATINAL DROPSY WITHOUT ALBUMINURIA.

THE frequency of dropsy as a sequel of scarlet fever led the immortal Cullen to mention it in his definition of that disease; and in more recent times, the almost invariable presence of albumen in the urine of those suffering from post-scarlatinal dropsy, has given rise to the very general opinion that the association of these two symptoms always indicates a morbid condition of the kidney analogous to Bright's disease. Thus Dr. Watson, in describing the dropsy that follows scarlatina, remarks:—"In this, as in other species of febrile dropsy, the urine is very dark, olive-coloured, albuminous, and sometimes bloody; and it contains fibrinous casts of the renal tubules, with epithelial cells intermixed." And Dr. Warburton Begbie, whose careful observations and extensive experience give great value to his conclusions, says:—"While there is no anasarca, the urine may be albuminous, but it contains no casts. As soon as anasarca occurs casts and epithelium, and sometimes even blood, are found associated with the albumen." And in the most recent work on the practice of physic, Dr. Aitken, in treating of the secondary affections of scarlatina, makes the following observation:—"The dropsy is generally accompanied with scanty and albuminous urine." And again, on the authority of Dr. Parkes, he says:—"The scarlatinal dropsy is very generally considered as most intimately connected with the kidney disease; and when the kidney disease is well-marked, the characters of the urine exactly resemble those in acute Bright's disease."

Dr. Basham, too, insists on the identity of the two diseases, and he points out that the characters of the urinary sediment, as well as the condition of the kidneys as ascertained by post-mortem examination, are similar to what is observed in morbus Brightii.

It is evident, therefore, that an albuminous condition of

the urine is regarded by almost all writers as a constant phenomenon in cases of post-scarlatinal dropsy; and, further, it is believed that the association of albuminuria and anasarca is generally connected with some form of renal disease. The occurrence, then, of any case of anasarca following upon an attack of scarlet fever, in which the urine is free from albumen as well as from tube casts, must be regarded as exceptional and worthy of being recorded. Three such cases have recently come under my notice, and I venture to think that a brief account of them cannot be without some interest, especially as the evidence in favour of the opinion that albuminuria may be wanting in this form of dropsy requires to be strengthened and substantiated.

Case 1.—G. H., æt. 2, when seen on the 17th of June, 1865, had general œdema of the face, hands, feet, and scrotum, which had come on about three days previously. His mother could give no cause for it, but stated that some weeks before she had noticed that the child was feverish and had a reddish eruption on the skin, which however did not stay out for any length of time. Since that time he had never been very well. His skin was very dry, and the face had that dingy pallor so generally seen in cases of albuminuria. The urine, however, was plentiful, and contained not a trace of albumen, nor any other renal product. He was treated with the ammoniated citrate of iron and the hot air bath, and in three or four days the œdema had passed almost entirely away. He remained under my care till the 17th of July, but although frequent careful examination of the urine was made, no albumen was ever detected.

Case 2.—A. S., æt. 2, was first seen on 25th August, 1865, and at that time the eyes were nearly closed from œdema of the eyelids and cheeks. The mother stated that, about three weeks before the child had suffered from a mild attack of scarlet fever, and that the swelling of the face had been present for about four days. She also stated that the child had been passing very little water of late.

The urine contained no albumen, and a microscopic examination failed to detect any tube casts or epithelial scales. Some purgative medicine was prescribed, and the warm wather bath was ordered. She was also to have plenty of cold water to drink. On the 30th of August, five days after she was first seen, all puffiness of the face had entirely disappeared; the urine was plentiful and free from albumen, and under the microscope only a few octahedral crystals of oxalate of lime were visible. On the 1st of September she remained perfectly well.

Case 3.—R. W., æt. 2, had had a red rash on his skin resembling the eruption of scarlet fever, and was feverish about a week before advice was sought. The eruption, however, speedily disappeared, and on the 27th November, 1865, his face and feet were noticed to be swelled. It was also observed that he had frequent desire to pass water, which was said to be scanty and "thick." I saw him on the 28th, and at that time he was very pale, his face was puffy, and the feet and legs œdematous. On the legs and soles of the feet the cuticle was beginning to desquamate. There were no febrile symptoms. The urine was pale, of sp. g. 1012, and free from albumen. Under the microscope no casts could be seen, but one or two epithelial scales were present. He was ordered to have as much cold water as he would drink, with a nutritious fluid diet. He was also to have a hot air bath. On November 30th, the urine was passed in considerable quantity and contained no abnormal constituent. By the 4th of December, the œdema had quite passed off, the urine flowed in large quantity, was free from albumen, but contained some octahedral crystals. The tincture of the muriate of iron was now prescribed, and on the 18th the patient passed from my care, being then in perfect health.

Here, then, are three cases in which the anasarca was clearly preceded by scarlatina, but in none of them could a single trace of albumen be discovered. Nor was there any indication that the kidneys were seriously affected. In cases No. 2 and 3 the urine was scanty, but the free action

of the kidneys was speedily re-established by simply administering copious draughts of pure cold water. And here I may be permitted to remark, that in many cases of so called albuminus neptitus I have seen the greatest benefit result from the cautious administration of pure water, accompanied by the occasional use of the hot-air bath. Indeed, in many cases, provided the febrile disturbance is not great, this disturbance alone suffices in a short time to remove both the albuminuria and the dropsy. Dr. Dickenson, of the London Hospital for sick children, was the first to point out the advantages of this system, and an interesting paper by him on the subject will be found in the *Edinburgh Medical Journal* for September, 1866.

Cases like the three which I have recorded distinctly prove that albuminuria is not necessarily invariably associated with post-scarlatinal dropsy. And although no notice is taken of this in most of our works on medicine, I think it is a fact which is not altogether wanting in interest and importance. The knowledge of it may be useful in leading practitioners to make a careful examination of the urine, both microscopically and chemically, in every case of scarlatinal dropsy that comes under their care; and it may also prove of benefit in simplifying the treatment of that affection, for if there is no albumen present, then there will be little need for anything more active than the administration of a gentle stimulant to the functions of the skin, the kidneys, and the bowels. Let me add, in conclusion, that the occurrence of cases of anasarca subsequent to scarlet fever, in which albuminuria is not present, should be noted and published, for although Rilliet and Barthez in their treatise on the diseases of children, and Dr. Parkes in his work on the urine, show that the evidence is in favour of the opinion that albuminuria may be absent in scarlatina dropsy, there is, nevertheless, a great want of carefully-recorded facts in support of that idea.

ON A

NEW METHOD OF APPLYING REMEDIAL AGENTS TO THE CAVITY OF THE TYMPANUM.

By EDWARD BISHOP, M.D.

SURGEON TO THE METROPOLITAN INFIRMARY FOR DISEASES OF THE EAR,
LONDON.

NOTWITHSTANDING the great improvements which have been effected of late years in the treatment of "Aural" disease, it must be confessed that much remains to be done.

The patient and practical investigations of our own countrymen, amongst whom stand pre-eminent the names of Yearsley, Toynbee, Wilde, and others, as well as those of our Continental and Transatlantic brethren, are worthy of all praise, having done much to raise the treatment of diseases of the "ear" in professional and general estimation, and, as a natural result, to take it out of the hands of a class of unprincipled charlatans, who preyed on public credulity. It must, however, be acknowledged, that the means at present at our command for treating several forms of aural disease, particularly those having their habitat within the cavity of the Tympanum, or middle ear, are few and often inefficient; the prejudices at one time existing against catheterism of the Eustachian passages, and also against insufflation of the middle ear, is rapidly dying out, and the opinion of Rau would now be very generally endorsed, viz., that the opposition to catheterism arises chiefly from a want of dexterity in the use of that instrument.

Politser's method, which is nothing more than *incomplete catheterism*, is practised and eulogised by some aural surgeons, and, doubtless, is an excellent alternative, where, from peculiarity of conformation, or from disease, there is some impediment to the complete passage of the catheter, or where the mucous membrane is so irritable, and the tensor and levator palate are prone to spasm from the slightest touch of the instrument; but such cases are rare—the exception and not the rule.

At the Metropolitan Infirmary for Diseases of the Ear (London), this method of Politser's has been adopted in a large number of cases, and the result compared with ordi-

nary catheterism—and there can be no question as to the superiority of the latter mode of treatment—and this is the *practical test*. I do not wish to detract from the merits of Politser's plan, as it is really valuable in the cases to which I have referred; nor is my object to write an article on the use of the eustachian catheter, hether considered as a *curative agent* or as a means of *diagnosis*, but to bring before the profession a mode of applying remedial agents *directly to the seat of lesion*, in those cases where disease exists in the middle ear, or in the passage leading to it. As far as I am aware, this plan is novel, yet I venture to hope it will prove useful, and become an adjunct to the means we already possess. I am induced to place confidence in it from the trials to which it has been subjected at the Metropolitan Infirmary, the details of a few of which I send you for publication.

It is impossible to over-estimate the good that has been accomplished of late years, and the light thrown on this form of disease; or it would be more correct, perhaps, to say, on the enunciation of the *FACT*, that in a very large majority of cases the *mucous membrane*, with its numerous ramifications and connexions, is the *SEAT* of disease. A gentleman, whose extensive hospital and private experience and whose accuracy of observation entitle his opinion to the greatest weight, writes as follows:—"Almost all diseases of the ear, associated with deafness, originate in a morbid condition of the mucous membrane of the throat, nose, and ear, which membrane becomes affected from a variety of causes, among which cold, the eruptive fevers or exanthemata (especially scarlatina), and stomach derangement, stand pre-eminent; and according as the disease terminates in simple thickening of the membrane, in adhesions, in disorganization of the whole mucous lining, in partial or total loss of the membrana tympani, in loss of the ossicula, or of the inner membrane of the fenestræ, so is the deafness more or less intense and confirmed."*

It is a remarkable fact, which, by your kind permission, I will take an early opportunity of showing in your journal, that there are comparatively few cases of deafness in which the disease ought to be attributed to the internal ear. The time has gone by when we can screen ourselves behind the term "nervous deafness," which, it must be confessed, was often made use of to hide our ignorance, and operated as a direct hindrance to a discriminating diagnosis.

The principal means available at present for treating affections of the tympanic cavity locally (the membrane of the tympanum remaining entire) are, *INSUFFLATION* by the *lungs* or by an *air press*; the *injection of steam*, *simple* or *medicated*, and the *injection of tepid water*, or *medicated solutions*. With respect to the last method, if sufficient quantity be used to come into contact with the whole of the lining membrane—which must be the case to do much good—mischief of one kind or another will result; the mastoid cells, lying on the same plane as the entrance of the eustachian canal, and the minute crannies in the cavity of the tympanum, are filled up, and often remain so, producing mechanical irritation and swelling of the lining membrane, the mischief being still greater if a medicated solution has been used. There are other objections, which your space will forbid my referring to; and I believe this operation will shortly be, if it is not already, abandoned by the best aural surgeons.

The first two methods are certainly valuable in many cases—the use of an air-press in the hands of an experienced operator being perfectly free from danger. The same objections may be urged against it as were formerly against insufflation by the lungs, viz., that the redundant and accumulated mucus in the tube may be driven into the cavity of the tympanum; that the current of air may break down too forcibly any existing old adhesions or ankyloses in the cavity left by previous inflammatory attacks; that it may luxate one or more of the articulations of the ossiculi, &c., &c. Practical experience, however,

* See Yearsley on Throat Deafness. 10th Edition.

shows that, as in the former so in the latter case these objections are more imaginary than real, and that insufflation by the lungs or the air-press may be adopted with perfect safety. It is also equally practicable to send vapour, medicated or otherwise, into the cavity, and to do this with advantage in some few cases; but it is evident those medicaments alone are available which are volatile and will pass off in solution in steam.

The importance of local treatment for the cure of disease purely local in its character is generally acknowledged, and one of the most valuable practical teachings of modern surgery is the recognition of the fact of how much may be done, and that with impunity, *within the cavities of the body*; therefore, any means by which we can safely apply a remedy to the seat of disease must be more or less valuable. Even within the "tympanic cavity," contiguous to such delicate and sensitive parts, much may be attempted, though great care is necessary in the manipulation.

The method I am adopting at the hospital is to apply lotion containing such soluble remedial agent as may be considered appropriate, by means of tepid pulverised water. It is evident, as far as the *principle* is concerned, lotion of any strength, up to the point of saturation, may be used. The quantity required to come into contact with the whole lining membrane is so small that there is not the least fear of mechanical injury, and by slightly turning the point of the instrument, the pharynx, the nasal passages, and the parts connected therewith, may all be subjected to the action of the remedy—an important fact, as it is found that the whole tract of mucous membrane lining these parts is generally suffering from the same morbid condition. As the pulverised lotion is driven

off in the finest state of subdivision, it may be sent into the cavity of the larynx; but on this point I have not yet had much experience, and therefore refer to it with diffidence. In the treatment of *ozena*, however, it will be found useful, as a solution of such agents as carbolic acid or creosote may be sent into every crevice and cranny of the tortuous nasal passages and the parts connected with them.

The apparatus consists of a small graduated glass syringe similar to that used for subcutaneous injection. The solution is gently forced guttatim into a cylinder, and at the point where it leaves the nozzle of the syringe it is caught by a current of air sent by a pump worked with a proper degree of force by the hand. This drives the fluid forward in a pulverised state. This small apparatus is then attached to an ordinary Eustachian catheter previously introduced, and suspended by a suitable apparatus. To ensure complete pulverisation, the end of the catheter is covered by fine gauze wire.

Some amount of dexterity is required in the successful use of the instrument, but this is soon accomplished by any one accustomed to the introduction of the catheter.

It is equally applicable to those cases where it is thought desirable to use Politzer's catheter, introduced a short distance only within the nasal passage—the pulverised solution finding its way through the Eustachian tube into the cavity of the tympanum during the act of swallowing.

The instrument described above has been made for me by Weiss and Son, Strand, London. I am conscious it is capable of much improvement, and in the hands of those highly scientific gentlemen has already been put into a *more* practical form than I at first anticipated.

A is a glass syringe graduated in minims.
B is a Eustachian catheter which fits the body of the instrument, and which is capable of being turned in any direction.

C is an elastic tube, to which an india-rubber air syring is attached.

The latter forms part of the instrument; but is omitted in the sketch to save space.

WESTMINSTER HOSPITAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—If you think the following case worthy of a place in your journal, pray let it appear.—Yours truly,

14 Savile-row, W. BARNARD HOLT.

STRICTURE OF THE URETHRA OF TWELVE YEARS' DURATION, INFILTRATES OF URINE, ABSCESS IN PERINEUM, SUBSEQUENT FISTULOUS OPENING, IMMEDIATE DILATATION. CURE.

By BARNARD HOLT, Senior Surgeon to the Hospital.

R. B., a labourer, was admitted August 10th, 1865. He had suffered from stricture for twelve years, and for some time previous to admission had only been enabled to pass his urine in drops. The late Mr. Brown of Stratham, under whose care he was, failing to get any instrument into the bladder, sent him to the hospital; upon admission it was found he had infiltration of urine to a great extent, there had been a large abscess in the perineum through which the urine escaped freely, his general health was much damaged, and he was much emaciated. I endeavoured to pass a small

catheter, but upon several occasions I failed to get beyond the first stricture, which was in the spongy part of the canal. I, however, eventually succeeded in passing the smallest sized gum elastic catheter through two other strictures into the bladder. This was fastened. Upon the following day I succeeded in introducing a larger size, and eventually I passed the dilator and split the strictures, which were very dense and offered considerable resistance to the tube. This being the largest size the urethra would take the urine was removed upon the first four occasions by the introduction of the catheter, and the after treatment was properly carried out. The fistulous openings speedily healed; the man could pass his water in a full stream, and his health greatly improved. He now only requires the passage of the No. 10 bougie once a month. This was another example out of many that have been already recorded of the rapid manner in which an obstinate and complicated stricture might be at once relieved, and the patient be speedily restored to health; it was also a good example of the rapidity with which urinary fistulae will heal with retaining any instrument in the urethra, so soon as the urethra is restored to its natural dimensions.

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 3, 1866.

THE NEW YEAR.

THE commencement of a New Year and the incorporation of THE MEDICAL PRESS AND CIRCULAR demand at our hands a few observations in reference to ourselves and to the profession to whose interests our columns are devoted.

As for ourselves, we would rather be judged by our deeds than our words, and we have so often known promises to be falsified by the results, that we refrain from making a display of professions, and prefer to await the judgment of our readers upon the efforts we make in their service. There is so much uncertainty in human affairs, that the commencement of a new undertaking must inspire even the boldest of editors with a certain misgiving, and all that can be done by those who are placed in such a responsible position is to buckle on their armour with the full determination to do their best and to trust to the indulgence of the circle to which they address themselves for any shortcomings in their editorial labours. With a full sense, then, of our duties and responsibilities, but with an earnest desire to do justice to all parties and to uphold the dignity and honour of our profession, we commence our New Volume. One point on which we desire to express ourselves most emphatically at the outset of our career is, that we entertain no jealous or envious feelings towards our medical contemporaries, but that we wish to hold our own ground on the basis of our own merits. There is room enough for us all, and we have no wish to jostle our neighbours on the highway where there is ample room for all to move about in ease and comfort. There is now no larger number of medical journals than there was thirty years ago, while the number of medical readers and of medical writers is infinitely greater. We therefore hope, and we believe not unreasonably, that we may continue to enjoy our due share of the patronage and support which have hitherto been extended to us in no niggardly manner, and which have encouraged us to persevere in the course which has led to our present successful and prosperous condition.

With regard to the profession in general, the prospects for the coming year are encouraging. The assembling of a new Parliament, and the accession to power of a new Premier, afford considerable hope that a favourable ear may be granted to the addresses, and it may be the complaints of the medical profession—a hope which is considerably strengthened by the presence, in the new House, of an opposition, formidable in point of talent and influence, if not preponderant in numerical strength.

The condition of the Army and Navy Medical Officers leaves much to be desired, and it may fairly be antici-

ated that the grievances of this important class of our brethren may be listened to in a friendly spirit, and redressed, as far as the exigencies of the public service will allow. For ourselves, we shall always be happy to promote the interests of these officers, and to urge their claims to the consideration of the government. We do not altogether endorse the opinions held by some of our contemporaries as to the present degenerate condition of the Medical Military Services, nor will we condescend to encourage class distinctions on the score of nationality; but we shall advocate the just claims of all the medical officers, whether English, Irish, or Scotch, to the favourable consideration of the legislature, and to the good opinion of the British nation. The present position of the English Poor-law Medical Officers appears to us to be so bad, that it must soon be altered for the better; and we are encouraged in this hope by the greater interest which is now evinced in the care of the poor by the public and the general press. That unfortunate class of our fellow-creatures who are brought within the operation of the Poor Law, has been hitherto treated with harshness and neglect by the local authorities, and with supercilious disdain by the leaders of public opinion; but it is now discovered, apparently for the first time, that the poor are human beings like ourselves, and that their welfare ought to be one of the cares of a humane and enlightened State. Hence we may conclude, that not many years, or perhaps months, may elapse, before we witness the demolition of those hideous Bastilles, where the sick and insane poor are too generally immured. At the same time we may hope that the Poor-law Medical Officers will be placed in a more independent position, both as regards their emoluments and their freedom of action, and be assimilated in their functions to the Medical Officers of our hospitals, lunatic asylums, and prisons. Our indefatigable friend, Mr. Griffiu, who has done so much for his brethren of the Poor-law Medical Service, will, we hope, be at last rewarded by living to witness a real improvement in the system of Poor-law Medical relief in Great Britain.

But there is another question which presses still more earnestly upon the attention of every member of the Profession in the United Kingdom, namely, an amendment of the present Medical Act. After immense labour on the part of our medical reformers through a long series of years, we have at last obtained a measure which has almost completely disappointed the hopes of all, and which, by the influence of parliamentary trickery, has been deprived of nearly all the provisions which might have protected the profession. As it is, we are all compelled to pay a pretty tax for registration, and then we are left to struggle as best we may, against a host of pretenders, who are actually encouraged by the law to practise medicine without any qualification or registration whatever. This monstrous anomaly in our Medical Act cannot be allowed any longer to continue, and it is gratifying to know that the Medical Council are fully alive to the necessity of amendment, and that the pre-

sident, Dr. Burrows, is energetically exerting himself to impress upon the government the amount of the injury and hardship inflicted by the operation of the present most imperfect measure.

The above are only a few of the questions which will be submitted for consideration during the ensuing year, but they are of paramount importance, and the Profession must bestir itself, if it expects any solid and substantial change in its present condition. It is in the columns of the medical journals that these matters must be discussed, and we shall never be remiss in opening our pages for their due and ample consideration.

THE CASE OF DR. PRITCHARD.

TESTIMONIAL TO DR. JAMES PATERSON.

ON Thursday afternoon, 21st ult., Dr. James Paterson was presented, in the Crown Hotel, George-square, Glasgow, with a testimonial subscribed for by a large number of the citizens, as a mark of respect for, and sympathy with him in the difficult position in which he was placed in connection with Dr. Pritchard's trial. There was a large number of subscribers present. Ex-Bailie Mitchell was called to the chair,

This is, perhaps, as objectionable a form of the testimonial nuisance as has ever taken place, and the opportunity thus given to Dr. Paterson of blowing his little trumpet, and the manner in which he has availed himself of it, will not raise him in the estimation of any right-thinking men. We are of these who perfectly agree with the Lord Justice Clerk, in his statement thus quoted by Dr. Paterson, that "as a citizen of this country, as a right-minded man, I had failed in my duty, in not preventing the destruction of human life; that I had acted in, what he considered, an improper manner, and had disregarded what was undoubtedly a public duty," and for these obvious reasons, setting aside completely all his peculiar notions as to medical etiquette, which, as the Lord Justice Clerk rightly remarked in his charge, ought never to be permitted to interfere with those higher duties which every right-minded man owes to his neighbour, and which are to be expected in a tenfold degree from every medical man, because his life is solemnly devoted to the preservation of life and the prevention of its destruction. Setting aside these peculiar views, however, and taking up the history of the case from the date of his first (and last) visit to Mrs. Taylor, we are told that he then made up his mind that Mrs. Pritchard was being poisoned by antimony; and what did Dr. Paterson do? *Nothing!* Again, when, at Dr. Pritchard's request, he visited Mrs. Pritchard six days afterwards (on the day of Mrs. Taylor's funeral), and found her (Mrs. P.) in the same state, what did Dr. Paterson do? *He assisted by his prescriptions in keeping up the farce, that she (Mrs. Pritchard) was labouring under gastric fever.* He never mentioned antimony either to Dr. Pritchard or to Mrs. Pritchard, nor did he take any pains clearly to ascertain the presence of antimony in the urine or the matters vomited. Mrs. Pritchard lived for more than fifteen days after this last visit—there was ample time to sear the murderer from his victims; there were ample means of doing it. But Dr. Paterson contented himself with nursing his suspicions, refusing a certificate of the cause of Mrs. Taylor's death,

and letting the murderer do his work. Did we believe that Dr. Paterson's suspicions were as strong as he now makes them out to be, we should not hesitate to state that his conduct actually made him an accessory before the fact; but we hope, indeed we may say we believe, that Dr. Paterson makes himself out to be worse than he really is. But what, it may be asked, ought Dr. Paterson to have done? That question is easily answered. He ought, either by an examination of the urine or matters vomited, to have made himself sure that his opinion was correct, and that antimony was being administered, in which case he might safely have put the matter in the hands of the Procurator Fiscal. Or, instead of prescribing champagne, ice, and grey powder, &c., for a case of antimonial poisoning, which he knew could not possibly do any good, he ought to have told Mrs. Pritchard that her symptoms were not those of any known disease, and were those of poisoning; this confidence would, at all events, have saved the victim, and might even have led to the sure detection of the would-be murderer. In regard to the proper conduct of a medical man when placed in such a trying position, we may refer to that of Dr. Addington, in the case of Mr. Blandy (Howell's State Trials, vol. xviii.), or to some interesting remarks by Dr. Christison, in regard to the Wooller poisoning case, in the *Edinburgh Medical Journal*, Feb. 1856, p. 711, &c.

A RECAPITULATION OF OUR ARRANGEMENTS.

UNDER the circumstances we will be excused for republishing the following details which appeared in our issue of December 20th:—

The MEDICAL PRESS AND CIRCULAR consists of not less than thirty-two pages, the same number and size as our present issue, to be increased as advertising space may require. Of these, twenty-four pages will be available for the letterpress, sixteen of which will be devoted to original contributions, excerpts from medical literature, and pure Medicine, Surgery, and Science in every form—the joint contributions of Ireland, England, and Scotland. Original communications to the Journal will, therefore, appear in the entire issue, and will be read equally in the three Kingdoms. The remaining eight pages will be composed of Leading Articles on Medical Politics and Ethics, and general information on all Medical subjects, and will be compiled and printed separately and distinctly for English, Irish, and Scotch readers, by a separate staff of writers in each country. Irishmen will thus continue to have the information which they wish for, without its being of necessity intruded on the notice of English or Scotch practitioners; while, on the other hand, readers in the sister countries will have the information which most interests them, each without interfering with the other.

To carry out this system with uniformity, and to give our Irish Subscribers equal advantages with our English and Scotch constituency, the subscription rate of THE PRESS will be reduced in future to £1 1s. 8d. per annum free by post, if paid in advance, and £1 2s. 6d. if not paid within six months. We venture to claim for THE MEDICAL PRESS AND CIRCULAR the following ad-

vantages, which we hope will recommend it to a large support from the Medical Profession:—

I. Enjoying the advantages of a triple connexion, and being conducted by a separate Editorial Staff in each of the three divisions of the United Kingdom, it must possess facilities for the acquirement of information which no other periodical conducted by a single local staff can have, while at the same time the strictest caution is exercised to prevent the affairs or interests of any one class in the profession from predominating. The purely Medical, Surgical, and Scientific portion of the Journal will be the joint contribution of the Schools of Medicine in London, Dublin, and Edinburgh, each equal to the other in talent and originality, while the Critical and Editorial Department will furnish material at once comprehensive and adapted to the requirements of each country.

II. While inferior to none in influence and merit, THE MEDICAL PRESS AND CIRCULAR is the cheapest weekly Medical Periodical in the United Kingdom. To attain which qualification the Subscription rate of THE MEDICAL PRESS has been considerably reduced. The Subscription will be 17s. 6d. per annum for Unstamped Copies, and £1 1s. 8d. free by Post. This latter rate is recommended, as it ensures greater regularity and rapidity of transmission. It is hoped that no Medical man who desires to keep pace with the rapid march of Medical Science will hesitate about the expenditure of a sum which would be amply repaid by the acquirement of a single fact of value in the practice of the profession.

III. THE MEDICAL PRESS AND CIRCULAR courts no competition with other Medical Journals, fully entitled to as much confidence as itself can be. It will, therefore, be published on Wednesday—a period intervening between the day of issue of other Medical Journals—in the belief that it will be read alike by every Medical man whose position enables him to subscribe to other Periodicals, and by the Practitioner, to whom a reliable Medical Record at an economical rate is of importance.

It would be a work of supererogation to point out to Advertisers the advantages which such an incorporation must insure; suffice it to say, that there will be no occasion henceforth to seek beyond their own shores for a certain medium for their announcements.

ELECTION FOR EXAMINER AT THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE Fellows of the College have been summoned to meet on the 4th inst., to witness the election of an Examiner, in the room of Dr. JEROME MORGAN. The gentlemen who are likely to lay their claims before the electors are Dr. C. F. MOORE (formerly Surgeon to the Peninsula and Oriental Company, and now Medical Officer of one of our City Dispensaries), Dr. MURNEX, and Dr. HEAD, one of the Surgeons of the Adelaide Hospital, and five others, whose names have not transpired. The claims of these gentlemen will depend in some respect on the view which may be taken of the functions of an Examiner. By common consent, the late Dr. MORGAN

had confined his examination to Pharmacy and Materia Medica; and the question arises, whether the candidate shall be selected as possessing special qualifications in that subject, or as dividing his examination among all subjects indifferently. As we understand, the bye-laws of the College do not specify that the Examiners shall confine themselves to a special subject; but on the other hand, it is considered by some persons that it may be advisable to recognize a specialty of subject in each examiner. The election is conducted by seven members of Council selected by lot and sworn to exercise their choice impartially.

WE understand that the late Dr. RICHARD CORBETT of Cork, whose death we announced in our last number, requested in his last testament that an examination of his body should be made, with a view of elucidating the obscure cause of his death. The examination was made by Drs. Townsend, Harvey, Gregg, O'Leary, and Haines. The name of Dr. Corbett, Professor of Anatomy in the Queen's College, Cork, was mentioned in the testamentary request, but was unable to be present.

MEETING OF MEDICAL MEN AT THE LIMERICK JUNCTION.

(FROM OUR SPECIAL REPORTER.)

ON Thursday last, the 26th inst., the meeting of medical men was held at the Limerick Junction. The meeting was one of the most successful that have ever been held at the Junction. The attendance was large, and the metropolis and nearly every part of the south of Ireland were represented. Almost every train that arrived at the Junction during the day brought a number of medical gentlemen to attend the meeting. Gentlemen were present from Dublin, Cork, Limerick, Tipperary, Galway, Cahir, and a number of other towns.

At five o'clock precisely the chair was taken by Dr. MACKESY.

Amongst the other gentlemen present were—Drs. Quinan, Dublin; Macnamara, Dublin; Mapother, Dublin; Hynes, Kinvarra; Harvey, Cork; Armstrong, Cork; South, Cork; Stafford, Arafman; Stokes, Cahir; Bennett, Bruff; O'Connell, Kilmallock; O'Connell, Templemore; Forsyth, Templemore; Russell, Thurles; Webb, Dundrum; Martin, Portlaw; Mullin, New Ross; Callaghan, Cork; T. Flynn, Cork; Goulding, Cork; O'Sullivan, Limerick; Brodie, Limerick; O'Brien, Co. Galway; Morrissey, Tipperary; Kennedy, Tipperary; Hamilton, Tipperary; W. Sadlier, Tipperary; Bradshaw, Bausla; J. O'Donnell, New Ross; Clarke, Mountrath; Power, Cappawhite; Chaplin, Killdinn; and Smyth, Ruther.

Drs. ARMSTRONG and SYNAN acted as Secretaries.

THE CHAIRMAN, who on rising was received with loud applause, said—Gentlemen, in taking the chair at so important a meeting as the present, called on a requisition so numerously signed, and attended by such a large number of medical practitioners of high standing in their profession, I cannot but feel flattered at the confidence reposed in me. The first in order, and the subject most interesting to the profession generally of the United Kingdom, is in reference to the working of the medical act and the medical council, and it is with much reluctance and with deep regret I have to say that the medical profession have been sadly disappointed from the want of unanimity, action, and firmness on the part of the medical council in not having as yet, after a lapse of seven years, made due provision for the preliminary education of students intended for the medical profession. If medicine is to be continued to be ranked as one of the learned professions, and its professors are to

hold that social status and position they should do, it is all important that young men, before they enter on their professional studies, should be well acquainted with general literature, and well grounded in the classics. That uneducated and incompetent persons have obtained, unfortunately for the public and the profession, such qualification from the want of a stringent examination has been abundantly proved by the examination of candidates for commissions in the medical department of the army. All candidates must have a diploma in medicine and a diploma in surgery before being admitted to examination, and yet one-third of those competing who were legally qualified in medicine and surgery failed to obtain the minimum number of marks required in the preliminary examination to qualify them for admission into the service. The examination of candidates to the medical department of the navy was still more discreditable, for some of the competing candidates, also holding legal qualifications in medicine and surgery, were so totally ignorant of the Latin language that they could not translate the pharmacopœia from which they were expected to prescribe for their patients. Now, all this is anything but creditable to us as a learned body, and must tend to bring the profession into public disrepute; and its explanation, I presume, is only to be found in the sharp competition that exists amongst the numerous licensing corporations for the fees paid on the diplomas of those they admit to medical or surgical practice, and the obvious prevention exists in the adoption of a uniform curriculum and course of study by each and all of those bodies granting licenses or degrees, which should be firmly enforced by the Medical Council, and if required by the Privy Council. A high standard of education in our profession is the more required at the present time, when it is generally admitted that the application of medical science to the health of the community is a matter of primary importance in the prevention of disease, by the removal or diminution of the causes tending to shorten the duration of human life. Within the last 20 years, the drain from famine, disease, and emigration, and war, suggests serious apprehension of an undue decrease in our population, reminding us that man is essential to his fellow-man, that the welfare of every class of society is inseparably linked together, and that numbers constitute an essential element of national wealth, prosperity, and security. Hygienic legislation, has, therefore, been more closely attended to by the government and the public; but although the importance of judicious sanitary legislation has been for some years generally acknowledged, yet the application of medical science to the preservation of the public health and the prolongation of the average duration of life, has been as yet by no means satisfactory; and it devolves on government to take this subject into mature consideration, and by giving appointments for hygienic purposes to medical men of attainments, with remuneration sufficiently liberal to enable them to withdraw from the curative practice of their profession, and devote their time to the investigation of the cause of zymotic disease, and the best means of prevention—a great boon would be conferred on society, the lives of thousands would be annually saved, and, by the increase of population from the increased average duration of human life, the prosperity and security of the empire would be placed on a permanent basis. Now, it seems to me that it is a subject of serious inquiry whether there should not exist some special distinguishing degree for such special attainments, which from year to year henceforward will, I trust, become increasingly valuable and popular. None of our universities or colleges at present confers a special degree for such special qualifications. The Colleges of Physicians and Surgeons, being for the examination of practitioners in curative medicine, could not be expected to undertake this duty. Recently Lord Granville, at the London University, expressed an opinion that there should be new university degrees to mark special attainments. It may, therefore, be expected that in the universities of the United Kingdom will be found a degree of B.C.M., Bachelor of Civil Medicine, and a De-

gree of D.C.M., Doctor of Civil Medicine, analogous to the degree of B.C.L., Bachelor of Civil Law, and D.C.L., Doctor of Civil Law, in the old universities. I need not remind you that whatever uncertainty there may be with regard to the specific nature of certain zymotic diseases, the history and course of modern epidemics have fully established the fact that when hygienic precautions have been neglected, then we may anticipate the heaviest visitation of the prevailing epidemic. Amidst the anxiety and urgent calls of practice, there are few of our body who have the time, however great may be our inclination, to study the course and progress of zymotic diseases. In times of epidemics we are too deeply engaged in struggle with disease—too deeply engaged in the recovery of our patients, to track, as it were, the footsteps of the destroying angel, and by long continued, patient observation, to ascertain, for the benefit of mankind, the hygienic reasons which, I doubt not, will be found to exist for the excessive mortality in our locality and the comparative exemption from disease in some adjacent village, where, from some fortunate cause, it may be accidentally, the laws of health have been attended to. I consider it due to Dr. Rumsey, of Cheltenham, to say that a special medical attainment was first suggested from reading his works, and the members of our profession are much indebted to that distinguished physician for his papers on sanitary and medico-legal subjects. Surrounded as I am by such a number of gentlemen of high intellectual power, practically conversant with the working of the medical charities in Ireland, I have confined my observations to the necessity of high education, as every matter connected with the medical institution and the charities of the country will be fully entered on by the movers and seconders of resolutions, and the gentlemen who will take part in the discussion. I must, however, call the attention of the meeting to the advantages the Medical Association presents in being a bond of union to all classes of the profession, and to the advantages the medical officers under the poor-law and medical charities acts have derived from the exertions of the association. I shall not now enter into particulars, but it must be acknowledged that there has been considerable improvement in the remuneration (although still inadequate) of medical officers since the formation of the Association, and this improvement is most observable in those districts where the Association has been in active operation, from the medical officers having the spirit and energy to join the association. I have at times differed with the Poor-law Commissioners, and have not on some occasions hesitated to express my views, but I give them every credit as high-minded gentlemen for anxiety to discharge their arduous duties with that justice and impartiality characteristic of all high officials under the British crown; and these gentlemen, and in particular Dr. Macdonald, the medical commissioner, deserve the thanks of the profession for the firmness with which they have resisted all attempts on the part of the union boards and dispensary committees to interfere in the arrangement of medical officers as to their private practice. I cannot conclude this address without expressing my deep and poignant regret at the loss the profession, the public, and Medical Association in particular have sustained in the death of Dr. Richard Corbett, Vice-President of the County and City of Cork Medical Protective Association—a man universally respected by his professional brethren.

Dr. HARVEY (Cork) rose to propose the first resolution. He said—Mr. Chairman and gentlemen, I have been called upon to propose the resolution which I shall now read:—

“Resolved—That the Medical Reform Act, as carried out by the Medical Council, has failed in securing for the Medical Profession the advantages originally intended, and that no adequate return has been given for the expenses incurred. We, therefore, suggest that a *uniform curriculum* of high preliminary education and of professional and scientific study be adopted for all licensing bodies, empowered under the act to grant licenses or diplomas in medicine or surgery, as the best means of maintaining the respectability and status of

the profession, and of securing to the public competent practitioners in medicine and surgery.”

On occasions like this, Mr. President, it always occurs to me to regret the great difficulty I find in expressing my opinions. I am, I know, gentlemen, a bad speaker, but shall not on that account shrink from the task that has been imposed on me. Permit me, in the first place, to express the great pleasure I feel in seeing so many of our brethren rallying round us to-day; and I trust that these meetings shall always be as well attended (hear, hear). These meetings are necessary—most necessary, for the well-being of our profession. It is by them that we are enabled to carefully examine the condition of our profession, to see what its wants or grievances may be, and how those wants may be supplied, these grievances removed. Owing to the peculiar nature of our avocations, it is almost impossible that a medical man in practice could occupy a seat in the House of Commons, and of the few medical men that do sit in the house, still fewer of the *esprit de corps* to undertake any work calculated to raise or assist the profession of their adoption. But, gentlemen, if we cannot speak in Parliament, we can through these meetings speak to Parliament. For some reason or the other, when we meet to endeavour to obtain our just rights, the public, to a certain extent, appear to ridicule our doing so. The other day I happened to sit near a country gentleman, and one of the first remarks he made was, referring to the meeting we are now present at, “Oh! so the doctors are at it again” The tone of his remarks was to throw ignominy and ridicule on our efforts; that we were begging for favours, that we were coming forward to the legislature with *argumenta ad misericordiam*, that we were always saying, “please Sir, more.” We have in this room a practical answer to such a charge as that. It was not, Mr. President, for any ease or selfish motive, that you leave the practice of the profession to which you are an honour, that you leave your private emoluments, and that you came here to occupy the chair you so worthily fill (hear). Nor, gentlemen, do these imputations lie against you who come here for the public weal, nor do they lie against him on whom the grave closed yesterday (Dr. Corbett, Cork), who was, as you all well know, at all times and under all circumstances so ready to bring to the aid of his profession his sound judgment and large abilities. It is unfair to look at the question as affecting the medical class alone. When one section of society suffers, the whole community must suffer; when one section of the community is unsound, the body cannot be healthy; when one section is not in a vigorous condition, it hangs as a drag on the whole body (hear). The mistake of under paying medical officers has been demonstrated by a fact that occurred within the last few days. A medical man held a government appointment, and was expected to support himself on the salary of £95 a year. The result of giving this man this wretchedly inadequate salary was that he committed a crime; he was discovered and convicted, and the community are now supporting in a convict cell a man who, had he been fairly paid, might now be a respectable member of society (hear). The rate at which boards of guardians pay their officers is so entirely inadequate as actually to prevent a man from being able to get proper conveyances, or otherwise debar him from properly looking after the poor. The result is, that the labouring man gets sick—the doctor cannot attend to him properly—his health breaks down, and he and his family enter the poor-house and are ever afterwards a burden on the rates. This happens, and must happen as long as boards of guardians will not allow medical men even a salary sufficient to enable them to get a vehicle to carry them from one end of their district to another. Until medical men are properly remunerated the poor must suffer—the ratepayer must suffer from this miserable and mistaken economy (hear). I maintain that the interests of the public and the interests of the medical men are not opposed to each other, and that in asking for our profession their just rights we are in reality asking the govern-

ment to put the social condition of the country in a sounder and safer position. With regard to the subject of the resolution itself, I believe that it is universally acknowledged that up to this we have received no benefit whatever from the Medical Act (hear). It is unnecessary for me to say that at the end of seven years we have not reaped one of the benefits we expected from that act. We expected that the Medical Council would take such steps as would enable us to secure a supply of really well-educated medical men, that they would enable the public to judge between qualified and unqualified men; and another thing we expected was, that all unqualified persons infringing on the provisions of the Medical Act would be punished. One alone of these has been granted to us, the registration of the qualified practitioners; but this is rendered useless to us, for the Council takes no trouble at all about the matter, and never think of prosecuting the unqualified men who violate the act. Again, I ask, during the seven years this act has been enforced, has there been any improvement in medical education, preliminary or otherwise? The question stands to-day just where it did this day seven years. The Medical Council have sent an immense number of questions, but they have taken no practical step whatever to insure that none but educated men shall enter the profession. In fact, within the last seven years things have become worse and increased facilities given to men to enter into the profession with little or no education. The result is that the Government boards have to examine candidates for medical situations on those matters, and to the disgrace of the profession twenty-five per cent. of the army candidates were rejected, because they were not men of ordinary education. What is the consequence of this? Why, that the profession into which those uneducated men are allowed to enter is looked down upon (hear). In the army and elsewhere its members are often treated with indignity, and that respect is not paid to them which their profession ought to receive. For seven years the council has been in existence, and it has as yet done nothing. It refuses to ask for further powers; it does not even act up to the powers it has. The council has not done its duty, and I must say that a council of one-fourth the number of the present one—a council composed of men free from all partial interests (hear), would be far preferable to the present council. The council, as it at present stands, is composed of a number of gentlemen, every one of whom is of necessity inclined to seek to promote the interest of the body to which he belongs himself. In the matter of education, what the profession should imperatively demand are not preliminary examinations, for these are quite useless; but that no man should be allowed to enter on his medical course without as a *sine qua non* having obtained an arts degree (hear). There would not then be any occasion for hampering medicine with French, natural philosophy, and other subjects, which are now in most colleges attached to the medical course. The whole four years, assuredly a sufficiently short space, should be devoted to studies purely medical. There should also, during the time devoted to medical education, be examinations partially devoted to practical tests. I would say that no education could be complete without the preliminary arts course, registration of the students, and the abolition of certificates, which are, I firmly believe, a gross evil (hear). When we have those things, no uneducated man can enter into a profession requiring the highest intelligence and the best education; and I do believe that by a persistent advocacy of our rights we will finally obtain from the Government the granting of all our fair demands (applause).

Dr. RUSSELL (Thurles) seconded the resolution.

Professor MACNAMARA—Before the resolution is put, I wish to say a few words. It appears to me that that resolution strikes at the root of the evils of which we complain. I entirely concur with Dr. Harvey that every young man before commencing his medical studies should have an arts degree. But I fear that before such a boon will be granted to the profession many years must elapse.

What I would suggest we should insist on at present is, that every boy, before commencing his medical studies, should have a preliminary examination; that examination being taken out of the hands of the medical corporations (hear) and given to some one body—a body somewhat similar to the middle class examiners at Oxford and Cambridge (hear). Every one of the medical corporations has a preliminary examination, but in many cases these examinations are mere shams. Any boy who can stammer through a line or two of Greek or Latin is sure of passing the preliminary examinations at some of the corporations, and nearly all of them recognize the certificates obtained at any one. Of course it is the interest of every corporation to get a student for the sake of the fees he will pay them, and accordingly, nearly everywhere, they are trying to have the preliminary examinations easier than elsewhere. (hear). The matter should be taken entirely out of the present hands and placed in those of some body to whom it would be perfectly indifferent whether the candidate passed or not (cheers). The Medical Council appears to have done nothing but tax us heavily, and then to bring disgrace on the country by a pharmacopoeia which has been rejected by the London College of Physicians, and in every possible way laughed at and snubbed (hear). While I am on the subject, I would also suggest that no student, having presented himself for his diploma at any corporation and having been rejected, should be allowed to present himself at any other corporation for six months after his rejection. I know as a fact that men having been rejected by us, instead of spending six months preparing themselves for another examination, go on board the steamer the very next day and go to another place; if they fail there they go to a third, and so on *unde, unde*, until in the end they are sure to return with their diploma (hear, hear). I state this from my own experience, and I appeal to Dr. Mapother, who can confirm my statement. If a man having been rejected at Dublin was not allowed to proceed for examination to either London or Edinburgh for six months, this system would be put an end to, and the man would spend his six months in improving his knowledge of medicine and preparing himself for his examination (hear).

The resolution was then unanimously adopted.

(To be concluded in next number.)

MEMORANDA OF THE MONTH.

(FROM A CORRESPONDENT.)

“Tros Tyriusve.”

A MEDIUM of communication between the three chief Medical Schools of Great Britain and Ireland is hailed with satisfaction in the colleges and hospitals. True science is of no country. We meet every week Russians, or Danish, or Dutch physicians in our visits to London hospitals; “strangers of Rome, Cretes, and Arabians;” medical men from India and Australia, all coming to learn what there is of novelty in London, in cancer cures, or ovariotomy, or ophthalmic surgery, or obstetrics, nearly all are they either coming from Edinburgh or going to Dublin to catch a passing glimpse of the distinctive surgery or medicine of each school, and asking eagerly in what this distinctiveness consists.

For all such a new periodical will be of interest. True science is of no country, and in being free from mere local politics of this or that city, a large space seems open for a new and useful journal. The present periodical was amongst the first to ask fair play for the treatment of consumption by Dr. Churchill's hypophosphites. Their value in some cases is now generally admitted. THE CIRCULAR first noticed, too, Dr. Brown-Séguard's lectures and dissections, when that eminent physiologist was invited to St. Bartholomew's by Mr. Paget, and was

rather pooh-poohed. Great discoveries, however, can afford to wait.

There are no such hospitals in the world, perhaps, as those in London. There are no such hospitals for extent. Within their walls, with a great amount of good dull routine, cases also of the very first importance are to be studied; within their precincts, men who knew Sir Astley or Mr. Abernethy tell over again their experiences. There are no such institutions for extent and opportunities of medical and surgical study. Yet how often have we wished within a dozen years or so that Dublin and Edinburgh were sufficiently noticed in London hospitals or college lectures, of the vast improvements in surgery of the present century. How have we wished, for instance, for a trial of the Dublin method of compression in aneurism, never fairly tried yet in London, or a fair exposition of Dr. Hughes Bennet's Edinburgh statistics of pneumonia. How have we wished to see acupressure tried clearly and honestly, without reference to which side of the Tweed it had its origin, or the amenities of its friends or enemies.

If learned colleges ignore such, or excision of the knee-joint; if in courts of justice we every month meet a clashing of medical opinion, arising very often from a want of extended experience, the remedy seems to consist in a broader style of journalism. Very closely, indeed, have the three countries been drawn together of late by such subjects.

One medical school, or one class of medical men—what with electric telegraphs and railways flashing information—cannot now afford to lag behind other schools or medical men; or if they do, they are certain to suffer in the estimation of patients and the public.

It is, perhaps, allowable to look back, and to look back with satisfaction, at the work done by THE PRESS and THE CIRCULAR in past years, in their different spheres or separate circles of influence.

THE PRESS, as the exponent of medical progress, with its monogram of “SALUS POPULI SUPREMA LEX,” has encouraged improvement, no matter from which of the points of the compass it came, and has not yielded to the mere book-shop interests of rival publishers: in criticisms of books or favours shown to special hospitals or hospital magnates, it has held the balance fairly in such things as the much opposed operation of ovariotomy, excision of joints, &c. Our London hospitals are overflowing with new facts and practical cases: so entirely neglected at present, that the hospital staff of such like institutions as St. Bartholomew's, the London, King's College, and Guy's, have tried of late to perish in the attempt, or publish a tithe of the cases themselves.

There is plenty of room for fair analytical reviews of books in the new journal. Dublin may do for English what Brussels does for French medical Literature; in small towns able men have time to read books which they review; in London the publisher wishes the review first and the book to be read afterwards! so, at least, it is supposed in hospitals; and given the name of a publisher, the character of the review follows with algebraic complexity and certainty.

The interests of one school of medicine or surgery are identical with those of others. The Registration Act binds us in our faculty or brotherhood, and it is our own fault if illegitimate pretenders make way amongst us, or if non-medical subjects in the interest of vestry clerks or wine merchants, grocers or druggists, engross such disproportionate space in medical weeklies.

STRYCHNIA POISONING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.
SIR,—In THE MEDICAL PRESS of the 20th inst. a case of cure of strychnia poisoning, supposed to be effected by alcohol, is quoted from Dr. P. J. Farnsworth in the *Philadelphia Medical Journal*.

I am at a loss to know on what grounds this cure is attributed to the Scheidam Schnaps, given with the intention "of smoothing his passage to the grave," or in other words of sending him drunk into the presence of his Maker.

It is distinctly stated in the account itself that the unhappy man "poured half a drachm of strychnia into his tobacco box, shook it down among the 'fine cut,' and took a large chew; part of the saliva he swallowed and part spit out; he did not remember how many chews he took, but there remained only enough for one more in the box."

As it is quite clear from the foregoing that the well-known antidote, nicotine, was taken with the strychnia, I consider that the cure should be set down to the tobacco and not to the gin.—I am, your obedient servant,

SAMUEL HAUGHTON.

Trinity College, Dublin, 23rd Dec., 1865.

THE UNHEALTHINESS OF IRISH TOWNS.—
NEWTOWNARDS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.
SIR,—I am much obliged to Dr. Jamison for his correction of my misquotation of the population of Newtownards, which in 1861 was 9543, instead of 2543, the number I copied from the "Official Irish Guide."

However, as I struck the cholera-rate, fever-rate, and death-rate for the union, not for the town, no misrepresentation followed. To describe the town, I quoted Dr. Jamison's own words in September, 1864: "Newtownards is dirty, unlighted, and unwatched at night;" and as he now pictures a very satisfactory state of things, the efficacy of town commissioners (since elected—three being medical men), has been clearly demonstrated.

That something more is to be still wished for, seems to me from two facts. 1. That the last four quarterly returns (which confessedly do not give us the whole truth) prove the death-rate of the district, over one-third of which is rural, to have been one in 32.3 against one in 86, the rate in the rural unions with which I contrasted the mortality of towns; and, 2. Dr. Jamison, as Registrar, has recorded in all these quarters, deaths which show that almost every form of zymotic disease has been alarmingly prevalent.—I am, Sir, your obedient servant,

E. D. MAPOTHER.

December 27, 1865.

DEATH OF DR. CHARLES G. RITCHIE,
LONDON.

AMID the festivities of this happy season, a dark cloud of affliction has suddenly settled over the home of one of the most respected physicians of Glasgow. Dr. Ritchie has been bereft of an only son. With a position attained by few at his time of life, and with a splendid future before him, Charles G. Ritchie, M.D., well known through his "Contributions to Assist the Study of Ovarian Physiology and Pathology," died in London on Friday, the 22nd ultimo, under the most distressing circumstances. On the morning of the day he died he had intimated by telegram to his relations in Edinburgh his intention to spend a few

days with them; and later in the afternoon he was found in a dying state in his consulting-room. All efforts to restore him were unavailing, and he died apparently from some poisonous agent with which he had been experimenting. After going through the usual curriculum, Dr. Ritchie studied for a considerable period at the medical schools of Paris, Vienna, and Würzburg, where he devoted special attention to the study of obstetrics, which was his favourite branch of medical science. Subsequently he held for a short period the office of Resident Physician to the Edinburgh Hospital for Sick Children, and afterwards went to London, where he settled in practice. During the last two years he has acted as assistant to Mr. Spencer Wells, in whose extensive practice Dr. Ritchie enjoyed unusual facilities for becoming acquainted with the diseases of women. In that capacity he was of immense service to Mr. Wells in making careful dissections and examinations of the numerous ovarian tumours removed by that eminent surgeon. There can be no doubt that if he had been spared, Dr. Ritchie would have risen to high rank as an accoucheur, for to good natural abilities were added the manners of a gentleman, and the most enthusiastic love for his profession. At the early age of twenty-four he has gone down to the grave, amid the regrets of all who knew him; and we are certain that if anything can blunt the sharpness of the arrow that quivers in a father's heart, it is the fact that the sympathies of the whole profession are extended to him in this the hour of his bitter sorrow.

(FROM OUR LONDON CORRESPONDENT.)

London, 30th December, 1865.

KNOWING as I well do the great demand on your space this week for other and more important matter than any small talk of mine, I shall content myself and please some of your readers by only sending you a short letter.

The principal, and indeed the all-engrossing topic of consideration just now in our medical circles is, the well-deserved honour conferred by our Sovereign Lady the Queen on the amiable and accomplished Professor Fergusson, F.R.S. Throughout the profession, and amongst the public generally, it is hailed with great satisfaction; even our newspapers, which seldom bestow any marks of commendation on the poor doctors, are unanimous in expressions of approval of the selection just made, and about to be confirmed. It has been justly observed that this is not a mere courtier's apotheosis into the Red Book—it is a reward well won by honest scientific efforts, and given where it was certainly due. It is acknowledged that no man represents more truly the advancing branch of medical science better than Sir William Fergusson, whose practice has illustrated that nicety of means, courage of nerve, humanity of heart, and anxiety to conserve, which has ever distinguished this recipient of his sovereign's favour. There may be two gentlemen in this metropolis, and one in the northern, whose friends may think the honour might have been conferred on older men, but the time has expired for measuring intellect by age. I heard one of those gentlemen at my club complaining that the title had not been conferred on a neighbour of Sir William Fergusson's, whom he displaced from his seat in the Council of the College of Surgeons, and that the gentleman in question had no alternative but to resign his serjeant-surgeonery; his, in my humble opinion, I don't think he will do. I will let you know directly the event takes place.

The next topic of conversation refers to yourself—viz. the amalgamation of two such important journals as the *Medical Press* and the *Medical Circular*. The announcement has been received with great satisfaction by a large and not unimportant circle in this metropolis, judging from the position of many who have made me offers of co-operation; and to show how little jealousy there is to fear from your contemporaries, I may mention that the *British Medical Journal* gives you an especial notice on the subject in its current number; but this is only what you might expect from one who always exhibits so much true gentlemanly courtesy as Dr. Markham. Differing as he often does from his contemporaries, he always gives credit where it is due; this is especially observable in the *questio vezata*, "Voting by Proxy," when he has spoken in terms of commendation of "a most elaborate table drawn up by the *Medical Times and Gazette*," showing the number of the Fellows of the College of Surgeons being members of the Association who voted at the last election, and which said table, no doubt, considerably influenced the Council in the decision at which it recently arrived, in direct opposition to the wishes of the Medical Association; yet the organ of that association of gentlemen, through its editor, re-argues the point in that high-toned spirit which should always influence journalists, and which has ever pervaded the pages of the *Dublin Medical Press*, now I see entered on its 26th year of existence. Strengthened as it is now with the *Medical Circular*, which has long since learned to run alone, and feel strong on its legs, success must attend your efforts aided by such a staff as I am glad to see you possess.

Referring again to association, I am glad to see Irishmen of all classes and distinctions in the profession banded together and about to hold an early meeting at Limerick, to take into consideration the present position of the profession in the various public services, as well as the law respecting the sanitary condition of the country, and to adopt such measures and make such suggestions in relation to these important subjects as may be deemed advisable previous to the meeting of Parliament. All honor then to the 262 gentlemen who have signed the requisition, especially those medical officers in the army and navy who have had the courage to do so. I hope the example thus set by the Irish Medical Association will be followed by the sister association in this country, when success will no doubt crown the efforts of those so much interested in all that relates to the welfare of the medical service of the country. The commission relating to army and navy surgeons has suspended its sittings; and as an illustration of the scarcity of surgeons in the latter department, I may mention that during the past year our College of Surgeons only examined twelve candidates and rejected a third.

Writing of the College of Surgeons, I may mention the publication for the first time of a Calendar of that institution, and a very interesting and creditable production it is for a first issue. I send you for publication in another column a few statistics; but I must be very careful how my pen runs on in favour of anything the College of Surgeons is capable of doing, or I shall be attacked in the *Lancet*, as a friend of mine has been in the current number of that periodical, where an obscure writer, or rather a writer with a defective vision, or perhaps both, insists that a paragraph which appeared in the *Times* evidently emanated from the College. If the writer had not been looking through a *gelatinised medium*, he would have seen that

either of the institutions therein named might have sent it, if so disposed.

Writing of gelatine and ophthalmic preparations in connection with it, so constantly vaunted in the advertising columns of the *Lancet*, I may mention that Mr. J. Z. Lawrence, the surgeon of the Surrey Ophthalmic Hospital, has introduced a much better because a more simple and portable article, viz: a stick or pencil charged with atropine, which an application to once or twice over the conjunctiva of the lower eyelid, displaces a sufficient quantity of atropine to dilate the pupil for all ophthalmoscopic or other purposes.

I am sure your readers will be glad to learn that the desire for medical in preference to legal coroners is increasing, and with a certain amount of success your countrymen only lately appointed a medical man. We have just received an important provincial district for Mr. W. H. Bennett, M.R.C.S., who has been elected for the Shaftesbury division of Dorsetshire. His opponent was Mr. Chitty, a lawyer, who on the great show of hands in favour of Mr. Bennett, declined demanding a poll. And now apologising for a very hurried letter, and sincerely wishing success to the *MEDICAL PRESS AND CIRCULAR*, I take my leave until next week.

MEETINGS OF SOCIETIES.

THE Edinburgh Medico-Chirurgical Society met in their Hall, 117, George-street, on Wednesday, the 26th ult.—Dr. P. D. HANDYSIDE, Vice-President, in the chair. Previous to the commencement of business, Dr. Handyside made some interesting remarks in regard to the remarkable case of double monstrosity presented by J. B. dos Santos, whom the members had a private opportunity of examining during the preceding week. In regard to this extraordinary case, Dr. Handyside, who made a most careful examination of the man both externally and also internally as far as that could be done by digital manipulation per anum, arrived at conclusions somewhat different from those propounded by Mr. Ernest Hart, in the *Lancet* for July 29th; but as these conclusions shall be presently published *in extenso*, we forbear for the present entering upon them.

Thereafter Dr. J. D. Gillespie read the notes of an interesting case of "Death from Chloroform," which had occurred in his practice. The patient, a young lady, had chloroform administered to her for the purpose of having a tooth extracted. When she appeared to be fairly over, and the extraction was attempted to be gone on with, the jaws were found to be firmly clenched. This obstacle having been overcome and the tooth extracted, Dr. Gillespie turned from the patient to procure some water to rinse out her mouth, but was instantaneously recalled to her side by a loud cry to find her apparently dead. The tongue, which was not however retracted, was at once pulled forwards, artificial respiration fully and fairly put in exercise, and further medical assistance at once procured, but unavailingly; the patient never rallied. Upon a *post-mortem* examination being made, the only thing abnormal discovered was a spasmodically contracted condition of the left heart, which contained no clot, and scarcely a drop of blood.

Dr. Roberts made some remarks upon the distressing character of such untoward events, and upon the importance of recording all such cases.

The retiring President, Dr. Douglas Maclagan, Prof. of Medical Jurisprudence, then read his valedictory address; and the public business having been concluded, the society proceeded to elect its office-bearers for the next year, who are as follows:—

President—John Moir, F.R.C.P.

Vice-Presidents—J. W. Begbie, M.D.; D. R. Haldane, M.D.; J. D. Gillespie.

Councillors—W. Saunders, M.D.; James Cappie, M.D.; T. Grainger Stewart, M.D.; J. Matthews Duncan, M.D.; Arthur Mitchell, M.D.; Robert P. Ritchie, M.D.; D. Argyll Robertson, M.D.; W. Stephenson, M.D.

Treasurer—G. W. Balfour, M.D.

Secretaries—Patrick H. Watson, M.D., 29 Charlotte-square; Charles Dyce, M.D., 42 Great King-street.

The next meeting of the Society takes place on Wednesday, the 3rd of January, when a paper will be read by Dr. Francis Skæe, upon "Insanity caused by Sunstroke, and by Injuries of the Head, with Illustrative Cases."

MEDICAL NEWS.

Dr. JOHN MOIR has been elected President of the Edinburgh Medico-Chirurgical Society, in the room of Professor MacLagan, whose term of office has expired.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practice, on the 21st inst. :—

Barracough, Robert Wooding Sutton, Streatham-hill, Brixton.

Bronholt, Robert David, Ryton xi Towns.

Folliott, James, Egerton Villas, Douglas-road, N.

Hembrough, John William, Walfham, Grimsby.

Manby, Frederic Edward, East Rudham, Norfolk.

Smith, Samuel H. Mett, Weaverham, Cheshire.

Spencer, George Outhwaite, Horbury-terrace, Notting-hill.

Weller, George, Fairfield Villas, Bow-road.

The following gentlemen also on the same day passed their first examination :—

Glaister, Harry Burrill, Royal Infirmary, Liverpool.

Meadows, Chas. John Walford, Guy's Hospital.

MEDICAL DIARY OF THE WEEK.

Thursday, Jan. 4.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 1 p.m.

ST. GEORGE'S HOSPITAL.—Operations, 1 p.m.

LONDON SURGICAL HOME.—Operations, 2 p.m.

WEST LONDON HOSPITAL.—Operations, 2 p.m.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 p.m.

ROYAL INSTITUTION.—3 p.m. Prof. Tyndall, "On Sound." Juvenile Lectures.

HARVEIAN SOCIETY OF LONDON.—8 p.m. Anniversary; President's Address, and Election of Officers.

Friday, Jan. 5.

WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ p.m.

Saturday, Jan. 6.

ST. THOMAS'S HOSPITAL.—Operations, 9½ a.m.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ p.m.

KING'S COLLEGE HOSPITAL.—Operations, 1½ p.m.

ROYAL FREE HOSPITAL.—Operations, 1½ p.m.

CHARING-CROSS HOSPITAL.—Operations, 2 p.m.

ROYAL INSTITUTION.—3 p.m. Prof. Tyndall, "On Sound." Juvenile Lectures.

THE NEW ANÆSTHETIC.

LONG before the blessed influences of ether or chloroform were known, the attention of medical men was directed to the discovery of some agent wherewith "to stail men's brains away" and thereby alleviate the agony of bodily suffering. Bloodletting, tobacco, opium, and many other substances had been tried and laid aside as unsuitable. And it was left to the distinguished professor of midwifery in the Edinburgh University, to make known to the world the therapeutic and anæsthetic properties of chloroform, an agent which is now in hourly use throughout the length and breadth of the world. This discovery undoubtedly has added the greatest lustre to his name; for although almost every department of the healing art has been benefited and enriched by his genius, still it is as the bestower on humanity of the mighty boon of painless surgery, that Dr. Simpson is best known and will be longest remembered.

Unhappily, however the administration of chloroform, even in the most careful hands, is not altogether free from danger. True the accidents that occur are very very few in proportion to the immense quantity that is used. For from one establishment in Edinburgh alone no fewer than 2,500,000 doses are dispensed in a year! Cases do now and then happen, nevertheless in which without any other discoverable cause, the patient dies under its influence; and such occurrences certainly tend to shake

the confidence of the profession and of the public in its safety. But we cannot well give up the use of chloroform until we have found a substitute which will be equally useful and at the same time free from risk. Such an agent has not yet been found.

And it is only by further experimenting with that group of chemical compounds which are known to possess anæsthetic properties, or by the discovery of some agent yet unknown, that we can expect to become acquainted with any substance that will excel chloroform as an anæsthetic. Dr. Simpson, with that unting energy which characterizes him, has made many experiments with many different fluids, and quite recently he has been using the bichloride of carbon, which he believes resembles chloroform more than any other agent he has tried. He gives the following account of it in a late number of the *Medical Times and Gazette*.

The last of these compounds—the Bichloride of Carbon is the new anæsthetic which forms the special subject of the present observations. It was first, I believe, discovered by M. R. Guault, in 1839. It has already received various appellations from various chemists, as Perchloroformene, Perchlorinated Chloride of Methyl, Dichloride of Carbon, Carbonic Chloride, Tetrachloride of Carbon, Superchloride of Carbon, Perchlorinated Hydrochloric Ether, and Perchlorinated Formene (see Guault's 'Handbook of Chemistry,' vol. vii., p. 355, and Watts' 'Dictionary of Chemistry,' vol. i, p. 765).

"If it becomes, as I believe it will, for some medicinal purposes, an article of the *Materia Medica*, it will require to have a pharmaceutical name appended to it, and perhaps the designation of Perchloroformene, or the shorter term Chlorocarbon, may prove sufficiently distinctive. In its chemical constitution, Bichloride of Carbon, or Chlorocarbon, is analogous to chloroform; with this difference, that the single atom of Hydrogen existing in Chloroform is replaced in Chlorocarbon by an atom of Chlorine, for the relative chemical constitution of these two bodies may be stated as follows:—

"The Chlorocarbon can be made from Chloroform by the action of Chlorine upon that liquid; and Gaucher has shown that the process may be also reversed, and Chloroform produced from Chlorocarbon, by treating it in an appropriate vessel with Zinc and dilute Sulphuric Acid, and thus exposing it to the action of nascent Hydrogen. The most common way hitherto adopted of forming Bichloride of Carbon consists in passing the vapour of Bisulphide or Bisulphuret of Carbon together with Chlorine through a red-hot tube either made of porcelain or containing within it fragments of porcelain. The result from this process Chloride of Sulphur and Bichloride of Carbon, the latter being easily separated from the former by the action of Potash.

The Bichloride of Carbon, or Chlorocarbon, is a transparent, colourless fluid having an ethereal and sweetish odour, not unlike Chloroform. Its specific gravity is great, being as high as 1.56, while chloroform is 1.49. It boils 170° Fahrenheit, the boiling point of Chloroform being 141°. The density of its vapour is 5.33, that of Chloroform being 4.2.

Besides trying the anæsthetic effects of Bichloride of carbon upon myself and others, I have used it in one or two cases of midwifery and surgery. Its primary objects are very analogous to those of chloroform, but it takes a longer time to produce the same degree of anæsthesia, and generally a longer time to recover from it. Some experiments with it upon mice and rabbits have shown this—two corresponding animals in these experiments being simultaneously exposed, under exactly similar circumstances, to the same doses of chloroform and chlorocarbon. But the depressing influences of chlorocarbon upon the heart is greater than that of chloroform; and, consequently, I believe it to be far more dangerous to employ as a general anæsthetic agent. In a case of midwifery in

which it was exhibited by my friend and assistant, Dr. Black, and myself, for above an hour, with the usual anæsthetic effects, the pulse latterly became extremely feeble and weak. In another case in which it was exhibited by Dr. Black, the patient, who had taken chloroform several times before, was unaware that the new anæsthetic was different from the old; her pulse continued steady and firm, although she is the subject of valvular disease of the heart. The surgical operations in which I have used chlorocarbon have been, the closure of a vesico-vaginal fistula, the division of the cervix uteri, the enlargement of the orifice of the vagina, and the application of potassa fusa to a large flat nevus upon the chest of a young infant. In all of these cases it answered quite well as an anæsthetic. The child did not waken up for more than an hour and a half after the employment of the caustic, which was used so as to produce a large slough. Its pulse was rapid and weak during the greatest degree of anæsthetic sleep. One of the mice exposed to its influence, and which was removed from the tumbler where the experiment upon it was made, as soon as the animal fell over, breathed imperfectly for some time after being laid upon the table, and then died.

"Chlorocarbon, when applied externally to the skin, acts much less as a stimulant and irritant than chloroform, and will hence, I believe, in all likelihood be found of use as a local anæsthetic in the composition of sedative liniments.

"In two cases of severe hystericalgia I have injected air loaded with the vapours of chlorocarbon into the vagina. The simplest apparatus for this purpose consists of a common enema syringe, with the nozzle introduced into the vagina, and the other extremity of the apparatus placed an inch or more down into the interior of a four-ounce phial, containing a small quantity—as an ounce or so—of the fluid whose vapour it is wished to inject through the syringe. Both patients were at once temporarily relieved from pain."

From this description it will be seen that the new anæsthetic does not possess any properties superior to chloroform. It is said it is cheaper, and less liable to cause sickness; but its disagreeable odour, its slowness of action, above all, its depressing influence upon the action of the heart, prove that, however useful the bichloride of carbon may become as an external application, it is assuredly not destined to supplant chloroform as an anæsthetic agent.

THE UNIVERSITY OF LONDON.

From a letter which has been forwarded by the University to all medical schools, it will be seen that the Senate is very much dissatisfied with the attainments of the aspirants who are seeking the scientific distinctions of that body. The chief complaint is as to the failures which have annually taken place at the preliminary scientific M.B. examination, and in July last it appears that no less than forty-three out of seventy-five candidates were rejected at that ordeal, the failures being chiefly in botany and zoology. The object of the letter is to recommend the medical schools, in connexion with that University, to train their alumni more carefully in these subjects, and, more especially, to insist upon their practical acquaintance with the objects of Natural History by the aid of specimens and museums. We entirely approve the sentiments expressed by the Senate, and hope that its recommendations will have the desired effect; but we cannot help thinking that the students are somewhat overtasked by the regulations of the London University. First comes the Matriculation Examination, which is almost equivalent to an ordinary examination for B.A., then the Preliminary Scientific M.B. examination, then the first M.B. examination, then the second M.B. examination, and at last the M.D. examination, or that for the Mastership in Surgery. Comparatively few students can have the time

and the money, to say nothing of the intellect, for these numerous and varied trials, more especially when an accurate knowledge of all the subjects is expected. The Senate seems rather to be legislating for medical students as they ought to be than as they are, but still we wish well to the attempt to raise a body of first-class practitioners.

SUMMARY OF THE WEEK.

SIR WILLIAM FERGUSSON, BART.

THE honour conferred by her Majesty on Sir William Fergusson will be regarded, not only by the friends of that gentleman but by the profession at large, with feelings of the liveliest satisfaction. It will be glad to learn that the department of the highest personage, legal coroner in law and sciences, and we need not add that the dignity could not have been more worthily bestowed. Although Sir William Fergusson has been for some time attached to the Court by holding the position of Surgeon Extraordinary to her Majesty, his personal services have, happily, never been called into requisition, and the baronetcy must, therefore, have been conferred chiefly on public grounds, and in recognition of the high standing which the recipient has already occupied in the surgical profession. Sir William's heir-apparent is a gentleman who, in social position and in all other respects, is well calculated to sustain the hereditary honour of his family.

DR. WATSON ON THE CATTLE PLAGUE.

THE *Times*, having already done an infinity of mischief by supporting the homœopathic and other forms of quackery, and recommending them in the treatment of the cattle-plague, has at the eleventh hour done a tardy act of justice to an outraged profession by inserting a letter from the respected President of the College of Physicians of London, containing some very sensible remarks upon the present epizootic. It is true that Dr. Watson does not tell the profession anything which it did not know before, but still the words of science, and indeed of common sense, have been of late so scanty in the columns of the *Times*, where medical matters are concerned, that it is positively refreshing to read Dr. Watson's modest and sensible observations. He proposes no cure for the cattle disease, and points out the folly of expecting that any should be found, as the disease resists cure like small-pox or scarlet-fever; but he strongly urges the preventive treatment by isolating the cattle affected by the malady, by prohibiting the movement of the beasts through the country, and by the establishment of dead-meat markets. It is possible that Dr. Watson's letter may produce a good impression in influential quarters, and at any rate, it may be hoped that it will put a stop to any more homœopathic follies in the leading daily journal.

ROYAL COLLEGE OF SURGEONS.

THE Council of this institution has just published for the first time, a calendar on the plan of those emanating from our universities. From this work it appears that there are now 312 fellows by examination, 254 honorary, and 247 by election, making a total of 1313. The members of the College number 14,375. The income of the College for the past year amounted to £11,634 4s. 8d., derived principally from the fees paid by students for examinations for the diploma of membership, which produced 48896 10s., a decrease of £1505 10s. from those of the preceding year. Elections to the fellowship pro-

duced £336 10s., whilst examinations for that distinction yielded only £115 10s. The rent of the chambers adjoining the College amounted to £690 15s. 8d. This item will, no doubt, be considerably increased next year by letting the residence of the late secretary. There appears a very serious diminution in the income arising from the examinations for the dental diploma, which in the preceding report was set down as amounting to £924, whereas in the statement now before us, it appears as yielding only £42, a falling of £882. There is a diminution also in the midwifery licence fees, of however only sixteen guineas; the amount

Dr. JOHN MOIR has been clear was £121 16s. against burgh Medico-Chirurgical year. The dividends on investment in government securities amounted to £1194 3s.

The disbursements amounted to £12,085 18s. 2d., being an excess over the receipts of £451 13s. 6d. The largest item under this head appears for salaries and wages, which amounted to £3,208 13s. 8d. The Court of Examiners received £3,059 14s. As the fees received for the midwifery and dental diplomas were small, so likewise were those paid to the examiners in those departments, the former receiving £58 16s., and the latter only £31 10s. The Government received £364 9s. for diploma stamps, and £762 4s. 6d. were paid for taxes and plates. There is an increase in pensions, which now amount to £444. The oldest member of the Council appears to be Mr. Lawrence, who was admitted a member of the College so long ago as the 6th of September, 1805, and who has twice filled the office of president. The oldest of the officials appears to be Mr. T. M. Stone, as filling the office of assistant-librarian in 1832. In continuing the analysis of this interesting calendar it appears that there have been only five baronets who have filled the president's chair since the incorporation of the College in 1800—viz., Sir Everard Home in 1813 and 1821; Sir David Dundas, who occupied that position in 1819; Sir Astley Paston Cooper, who filled the office in 1827 and 1836; Sir Benjamin Collins Brodie in 1844, and the recently appointed Sir William Fergusson, who has that honour looming before him. Of the knights who have filled that honourable post are, Sir Charles Blicke in 1803 and 1810; Sir James Earle in 1807 and 1817; Sir William Blizard in 1814 and 1822; Sir Anthony Carlisle in 1825 and 1837. There have been and are other baronets and knights on the list of fellows and members, as amongst the survivors are Sir S. L. Hammick, Bart., Sir Rutherford Alcock, H.M. Minister at Japan, Sir Henry Cooper of Hull, &c. Amongst deceased knights are Sir Lurford Harvey, Sir Patrick Macgrigor, Sir John Webb, Sir Charles Bell, Sir James Eyre, &c. There also appears in the list of fellows and members two M.P.s, as Dr Brady for Leitrim, and Mr. W. J. Clement for Shrewsbury; there also appears to be several clergymen, at the head of whom appears the honoured name of F. Thomas MacDougal of Sarawak, the Lord Bishop of Borneo.

TO CORRESPONDENTS.

THE Editor begs to apprise his querists that in future all inquiries, hitherto answered by private note, will be responded to in the Correspondents' column of the Journal.

All communications, letters, and books for review will be acknowledged in due course.

Letters and communications have been received from Dr. Barnard Holt, Dr. B. W. Foster, Birmingham; Dr. Edwards, London; Dr. McKinlay, Paisley; Dr. Harvey, London; Dr. Elliott, Dublin; Dr. Shinkwin, Cork; Mr. Harry Lobb, London; Dr. McBerrier, Glasgow; Dr. Courtenay, London; Dr. Lyster, Liverpool; Dr. Mapother, Dublin; Dr. Donovan, Skibbereen; Mr. Milton, London; Dr. Charles Kidd,

London; Dr. G. W. Balfour, Fdinlugh; Dr. Morrell Mackenzie, London; Dr. Mackesy, Waterford; Messrs. MacLachlan and Stewart, Edinburgh.

REPRINTS OF CONTRIBUTIONS.

CONTRIBUTORS TO THE MEDICAL PRESS AND CIRCULAR are informed that their communications can be reprinted in book form at a very moderate cost immediately after they have appeared in the Journal. It being assumed that the contributions have been properly corrected and revised before publication in the Journal, and great delay and no little expense having been incurred in consequence of alterations made subsequently to publication, it is notified no proofs can in future be sent out or alterations made in the matter before reprinting. The rates of charges for reprinting will be forwarded on application at the office.

COMMUNICATIONS POSTPONED.

The following communications are unavoidably postponed, having reached our office too late for insertion:—

Dr. G. K. H. Paterson, Perthshire, on the Treatment of Exhaustion Occurring During Labour. Three Cases of Functional Aphonia Cured by the Application of Galvanism to the Larynx, by G. Johnson, M.D., F.R.C.P., Professor of Medicine in King's College. On the Treatment of Ganglion of the Wrist, by Dr. Donovan, Skibbereen. Selections from Dutch Medical Literature, translated by W. D. Moore, M.R.I.A. On the Health of Towns, by Dr. McCormac, Belfast. Observations on the Treatment of Spontaneous Vaginal Hematocele, translated from the French by Dr. George Bolster, Newcastle, County Limerick. On the Treatment of Cholera, translated from the "Bulletin de Therapeutique" by Dr. Isaac Ashe, Castleblayney. A Leading Article on Scepticism in Medicine. Letter of the Senate of the London University on Preliminary Examinations. Letter from Dr. Coleman, Milton Malbay, on Unhealthiness of Irish Towns. Case of Strangulated Hernia cured by Operation, by Dr. Horan, Coochill, County Cavan. Meteorological Report, Dr. Hanlon, Portarlington. Letter from our Belfast Correspondent. Proceedings of the Surgical Society of Ireland. Proceedings of the Harveian Society of London. Dr. O'Rorke, Report on Treatment of Epilepsy by Arteriosclerosis Vulgaris and Cardium Pretensis. Review of Reports to the Lord Provost and Magistrates on the Pathological Appearances, &c., of the Cattle Plague.

MR. E., UPTON NOBLE, SOMERSETSHIRE.—The village of Upton Noble has lately been agitated by a difference of opinion as to a point of professional etiquette between two medical practitioners—Dr. Banks and Dr. Higinbotham. It appears that the former having been called in to attend a child pronounced the disease to be scarlatina; but after the patient's death, Dr. Higinbotham called upon the parents and obtained leave to open the body, and then declared the disease to be inflammation of the larynx. It should be mentioned that Dr. Higinbotham's object in visiting the house of the patient was to make inquiry as to a sister of the deceased, as he wished to take her into his family as a nurse for his children. He was, therefore, anxious to ascertain the nature of the complaint of which the patient died. But as is usual in small villages, the difference of opinion between the doctors caused a great commotion, and an inquest was the result, the verdict being "death from natural causes." We do not reprint the inquest "in extenso," because the points of interest are really very few. We think that it is difficult, after death, to determine that scarlatina has not existed, and we think it a pity that Dr. Higinbotham should have made such an assertion. Dr. Banks does not seem to deserve any censure in the matter, and the verdict completely exonerates his reputation from any blame, if indeed any ever attached to it, which we very much doubt.

CHIRURGUS, Isle of Man, asks us to give a brief and precise statement of the Banting system of reduction, as he wishes to apply it in a case he has in hand. We really feel unable to comply with the request, and must refer our Correspondent to Mr. Banting's pamphlet on the subject. We may state generally, however, that the system consists mainly in an abstinence from sugar and farinaceous food.

DR. FRASER'S paper will be acceptable.

THE OBSTETRICAL SOCIETY OF LONDON.—The notice has been received.

DR. CARPENTER'S letter, enclosing an address by the University of London to Medical Schools, has been received.

X.—The gentleman in question is quite able to blow his own trumpet without any assistance on our part.

NEO.—The article contains passages which might be deemed libellous.

CHIRURGUS.—Among the surgical knights whose names have been lately published we do not find that of Sir Ranald Martin, who certainly adds dignity to the order to which he belongs, and who ought not to have been omitted.

THE Editor is anxious to secure the services of a local Correspondent in each large town in Ireland. He will be happy to communicate with gentlemen with that object, on their sending their address. He is also desirous of appointing a gentleman to act as Hospital Reporter in Dublin, at a moderate salary.

MEDICAL NEWS.

THE Editor solicits the kind assistance of his readers in the compilation of his Medical News. He will be glad to receive from Subscribers notifications of Vacancies, Appointments, Births, Deaths, Marriages, and newspaper cuttings of medical interest.

MEDICAL OFFICER TO THE METROPOLITAN POLICE.—Dr. Nedley has been appointed as the successor of Dr. Ireland in the position of medical officer to the Metropolitan Police.

DR. NARBURTON B. BIE has been elected one of the Physicians to the Royal Edinburgh Hospital for Sick Children, in the room of Dr. Moir, resigned.

MR. WM. TURNER, M.B., Demonstrator of Anatomy in the University of Edinburgh, has been elected a Fellow of the Society of Antiquaries of Scotland.

DR. J. D. COWAN has been appointed Professor of Materia Medica in the University of Glasgow, in the room of Dr. Easton, deceased.

ELECTRIC GARMENTS IN THE TREATMENT OF DISEASE.—In order to render a current of electricity capable of passing through a patient, Mr. Harry Lobb has invented some electric garments which are made to fit any portion of the human frame. Each garment has an insulated conducting wire attached to it, by which it may be brought into connection with any kind of battery; and the advantages claimed for the electric garment are, their simplicity of application, their great efficacy, their portability, and their cleanliness. The electro-magnetic, the magneto-electric, and the voltaic batteries in use are used with the garments, and they are said to be used with great advantage in many nervous and painful complaints, as, anæsthesia, muscular paralysis, hemiplegia and paraplegia, and even in some cases of suspended animation. The electric garments are manufactured and sold by Messrs. Maw and Cobb, Aldersgate-street, London, and by all chemists and druggists in the United Kingdom.

THE "PALL MALL GAZETTE" AND "DR." HUNTER.—The *Lancet* states that an action to libel has been commenced by "Dr." Hunter against the *Pall Mall Gazette*, in consequence of the articles which appeared in that able and spirited journal on the occasion of the recent trial.

CHRISTMAS HOLIDAYS FOR EDINBURGH MEDICAL STUDENTS.—It was the intention of the Senatus of the University not to grant to medical students this session the usual short recess at the end of the year, and notice of the resolution was intimated in the University Calendar. As Christmas drew nigh, however, the members began to think that it was rather to be desired that they, alone of all the students, should be deprived of joining the family circle, and mingling in the social pleasures which belong to the merry Christmas time. Meetings were held, and a memorial, signed by about 320 medical students, was drawn up and presented to the Senatus, asking that four lectures during the last week of the year might be omitted, thus allowing a recess of ten days. This request the Senatus refused, and the students applied to the University Court. The Court was of opinion that for this year the Senatus might grant the usual holidays, but left the matter to be decided by them. It was ultimately resolved by the Senatus that the Medicals, in common with the Arts, Law, and Divinity students, should be released from attendance at classes from Friday the 22nd December till Tuesday

the 2nd of January, 1866, so that by this decision 420 medical students have had it in their power to see the old year die and the new one born, amid the familiar faces of their friends and the dear associations of home. A similar privilege was granted to the students attending the extra-academical school.

BIRTHS.

Announcements of Births, Deaths, and Marriages must be authenticated with the card of the sender, and are inserted free of charge.

Dec. 21, at 10, Morrison's-quay, Cork, the wife of E. R. Townsend, jun., M.D., of a daughter.

December 25, at Dundrum, the wife of Dr. Bernard, of a daughter.

On the 23rd inst., at 62, George's-street, Limerick, the wife of J. J. Gelston, M.D., of a daughter.

December 24, at 15, Gardner's-place, the wife of W. B. Jennings, Esq., M.D., of a son.

At the Royal Dockyard, Portsmouth, the wife of Dr. Gordon, R.N., of a daughter.

December 27, at the residence of his father, Altamont-terrace, Westport, the wife of Dr. F. Noel Burke, Medical Director, United States Army, of a daughter.

MARRIAGES.

December 27, by special license, at the Church of St. Andrew, Westland-row, by the Rev. Mr. Patterson, assisted by the Rev. Mr. Pentony, Malachy J. Kilgariff, Esq., L.R.C.S.I., 47, Harrington street, to Katie, eldest daughter of Joseph Punnnett, Esq., 30, Lower Pembroke-street.

December 19, in St. Mary's Church, Clonmel, by the Rev. Francis Tenquest Brady, A.M., Rector of the Parish, and Chancellor of Lismore, Henry Robert Perry, Esq., of Liverpool, son of the Rev. Henry Crittie and the Lady Catherine Perry, of Tulamelan Rectory, county Tipperary, to Harriet Jane, youngest daughter of William James Shiell, Esq., M.D., of Clonmel.

DEATHS.

December 28, at Kesh, William Johnston, Esq., M.D., in the 70th year of his age.

November 19, at Bombay, of consumption, Letitia, wife of J. A. Fitzpatrick, Esq., M.D., King's Dragoon Guards, and only daughter of Hugh Corley, Esq., of this city.

December 21, at the residence of his father, James Henry, M.D., Brougham House, Birkenhead, Staff-Assistant-Surgeon Richard Henry, late Royal Artillery.

December 20, at the residence of his father, Newtown House, Tullamore, William Blakely Tarleton, Esq., M.D., of Banagher, King's County.

On the 22nd inst., at his residence, South Mall, after a long and painful illness, Richard Corbett, Esq., M.D., aged 66 years.

MILITARY MEDICAL PROMOTIONS.

Staff-Assistant Surgeon T. Maunsell, at present in medical charge of the detachment 5th Fusiliers, at Ship-street Barracks, has been ordered to take medical charge of the detachment 60th Rifles at the Linen Hall Barracks.

Staff-Assistant-Surgeon White, ordered for duty in Dublin, on arrival will take medical charge of the detachment 5th Fusiliers at Ship-street Barracks.

THE MEDICAL PRESS AND CIRCULAR.

BEING THE INCORPORATION OF THE TWO JOURNALS HITHERTO KNOWN AS THE MEDICAL PRESS AND THE MEDICAL CIRCULAR.

A SPECIAL EDITION OF "THE MEDICAL PRESS AND CIRCULAR" will be printed for each of the Divisions of the United Kingdom, and will be published simultaneously in London, Edinburgh, and Dublin. Advertisements will therefore appear in the three Editions, including the Issues of the "THE MEDICAL PRESS, THE MEDICAL CIRCULAR, and THE EDINBURGH SPECIAL EDITION," now for the first time Established. This arrangement will guarantee a Circulation unrivalled in extent and peculiarly the property of "THE MEDICAL PRESS AND CIRCULAR.

CLINICAL SURGERY.

LITHOTRITY.

By JOHN HAMILTON, F.R.C.S.,

SURGEON TO THE RICHMOND HOSPITAL, AND TO SWIFT'S HOSPITAL FOR LUNATICS.

No operation in surgery is so satisfactory as lithotripsy, when the stone is small or of moderate size, and the bladder so little engaged that it is not irritable. In the two following cases the progress and result were most favorable:—

Case 1.—John Hudson, *ætat.* 54, a healthy-looking man, admitted into the Richmond Hospital April 29th, 1864, suffering from great pain after having passed water, lasting for twenty minutes. While passing water the stream would suddenly stop and a mere dribbling ensue. The urine had white shreds in it and deposited a thick slimy matter. He passed a small stone so long ago as 1836, but remained well till a few months since. Mr. Hamilton introduced a silver catheter and detected a stone. He then passed the lithotrite of M. Civiale, and at once seized the stone (which by measurement appeared about the size of a nutmeg) and broke it. The fracture, Mr. Hamilton said, was soft. He then again seized it, and it broke with an audible crack, the stone, though with a soft outer layer, being evidently a hard one. Then the instrument was withdrawn, the hollow of the female-branch was filled with partly a white calcareous mass of the triple phosphate, and partly with dark brown hard fragments of the oxalate of lime. The next day he passed some fragments of small size. The third day he was suffering from irritation in the passage, and had had a rigor. On examination Mr. H. found a rather large piece stuck at the end of the urethra, near the orifice, which he extracted. It proved to be oxalate of lime. He had no further trouble after this, and left the hospital well. He returned in a week perfectly free from any symptom of the disease.

Case 2.—Matthew Higgins, aged 66, a healthy-looking farmer, residing at Bossfort, county Longford, was admitted into the Richmond Hospital Friday, July 21, 1865, with symptoms of stone in the bladder.

Eleven years ago he felt much pain in the right kidney. At the end of four days the pain left the kidney and went gradually down the groin, when it suddenly ceased; but immediately after he felt something in the bladder, followed by retention of urine, for which his medical attendant passed a catheter. This was followed by the passage of a small calculus resembling a piece of resin. He remained free from any symptoms of gravel till last May. On the 11th of that month he again suffered from pain in the same kidney, which went down the groin as before, terminating in much irritation in the bladder, pain in passing water, with occasional stoppages, pain at the lower part of the end of the penis, and an unpleasant straining feel in the rectum. Once or twice he observed a little blood. His medical adviser in the country recommended him to go to Dublin to be relieved of the stone. He had observed since the stone had entered the bladder, that if he remained quiet in bed on his back he was free from uneasiness, but that when he got up and walked about the irritation began and the desire to pass water. The urine he passes is tolerably clear; no slimy deposit.

He was told to keep his water for a few hours previous to the hospital visit. Mr. Hamilton passed Civiale's lithotrite and caught the stone at once. It was the size of a small marble, and very hard, which led Mr. Hamilton to say he was sure it was oxalate of lime. It broke with an audible crack. The instrument would not close entirely from the fragments remaining between the two branches, but it came on pretty freely till at the orifice, when the resistance to the extraction was so great that Mr. Hamilton divided a small portion of the edge of the orifice at the frenum. The spoon-bill, or female branch of the instrument, was full of tightly-compressed detritus, of a dark brown colour and rather square fracture, oxalate of lime.

Monday, July 24th: The only sensation is a little irritation, as if there was a small piece of grit in the passage, but all feeling of stone gone.

25th: Perfectly well. He yesterday passed a small piece of the calculus, but to-day no species of irritation whatever, and he left town for his home.

In this case there was a little difficulty in the introduction of the instrument, probably, considering his age, from some enlargement of the prostate. The stone was very hard to break, so that I used a towel to act more decidedly on the screw, which I should not have done had the stone been larger, for fear of putting too great a stress on the strength of the instrument.

The next example will show that when an oxalate of limestone is large a stronger instrument than Civiale's lithotrite becomes necessary. In such a case Weiss' instrument must be used. It also shows how much more serious the complications become as the stone is larger.

Case 3.—George Conan, *ætat.* 20, admitted, complaining of difficult and painful micturition, pain most felt at the end of making water, and at the end of the penis—the last not marked. The water generally clear, but depositing a sediment. Five weeks since it appeared red and bloody. Walking rather gave him ease, nor did he suffer from the motion of a rough car. The frequency was great and disturbed him constantly during the night. The stream, free at first, would diminish and dribble away from him. He suffered less at some periods than at others.

At ten years' old he got a severe fall by a person suddenly letting go a stick he held. After that he passed bloody urine. He suffered occasionally from irritable bladder, but was sometimes free from it. For the last six or seven weeks he has suffered severely from his present complaint, with a pain across the loins and in the stomach. His general appearance is healthy. Pulse 90, and nervous, and he appears of a nervous temperament.

He has congenital phimosis, but the foreskin could be retracted sufficiently to expose the orifice of the urethra. I sounded him on Monday and at once detected a stone. The next day I operated, using Civiale's lithotrite, and without difficulty caught the stone, which appeared to be about the size of a large walnut. No effort with this instrument would break the stone, so after strenuous exertions, twisting the screw by aid of a towel (a very wrong proceeding), I gave up further attempts, and disengaging the stone withdrew the instrument. He bore the operation well. He objected to chloroform. A few days after I operated again, but this time with Weiss' screw, which is not only stronger but the blades armed with chisel or wedge-shaped teeth. It required some degree of force, and broke with an audible crack. Two large fragments were caught and broke readily.

8th: He showed me a large collection of pieces of mulberry calculus that he had passed after the operation. Some of them presented the lobulated surface and dark colour of the mulberry calculus, smooth and polished, and inside, each lobule presented on its fractured surface, a regular striated crystallization. There was a good deal of muco-purulent deposit on the vessel, owing probably to the irritation of the fragments. I injected some tepid water.

9th: I operated with Civiale's lithotrite, but some of

the fragments were large and could not be broken by it. When withdrawn the scoop of the instrument was full of fragments of oxalate of lime. One large fragment that I could not break I found it hard to dislodge from the instrument.

Oct. 10th: I was agreeably surprised to find him remarkably well to-day. He had passed many good sized fragments.

14th: I used Weiss' instrument and caught fragments four times. They broke with a loud crack. One large piece measured ten lines, another seven. He suffered very little.

16th: He has passed a good deal of detritus, but less than after former operations.

20th: A very successful operation, large and numerous fragments caught and broken. He suffered more pain than usual. The next day he passed a number of broken pieces.

Nov. 1st: Very comfortable up to yesterday, when he felt heavy, with some tenderness of the left testicle, which to-day presents the characters of orchitis; the serotum red, the testicle enlarged, but the epididymis not hard as in gonorrhœal orchitis. Goulard's lotion locally, and the administration of the diaphoretic mixture, with a little antimonial wine, subdued the inflammation, and at the end of a week the testicle was nearly natural and not tender. I therefore operated, caught some rather large pieces and broke them.

10th: Two days after the operation he presented me with a paper full of pieces that he had passed. He said there was a good deal of fine gravel that he could not collect. The last piece passed was angular and sharp, and caused a good deal of uneasiness in the passage. He passed a single piece after this, and felt so well that on the 13th he left the hospital apparently well. A week after, November 19th, he came back, suffering from some of his old symptoms; I therefore introduced the lithotrite and caught readily rather a large piece and crushed it. In the evening a fragment stuck just behind the orifice of the urethra. Mr. O'Brien, the resident pupil, caught it with a forceps, but could not extract it. The patient got rigors, followed by fever and pain in the part, and distress in making water and difficulty. The glans penis was swollen and œdematous looking, and there was some purulent fluid oozing from the orifice. I tried Le Roy's instrument for the extraction of pieces of stone from the urethra, but it could not be got behind the fragment, for the urethra was so dilated behind it that the instrument pushed the stone back from the orifice. I therefore got out the stone by gently urging it forward to the orifice again and caught it with a strong forceps, and pulling it forward against the orifice enlarged the latter by a slight nick with a sharp bistoury, when the stone was readily extracted. A hip bath and ten drops of laudanum were ordered immediately after. The piece was very large, the largest that had yet come away. The next day he was quite comfortable and passed two pieces. Feeling so well he left the hospital.

May 23rd: He came to the hospital with renewed symptoms of stone, and a large piece was detected at the neck of the bladder. He could not bear the injection of more than four ounces of water, and he could not retain it for more than a minute. I therefore ordered rest in bed, a hip bath, and the *pareira brava*, with liquor potassæ, determined not to operate till the bladder was less irritable, and till he bore the injection of a sufficient quantity of water. In two days after, from the treatment, and most likely from the stone having been pushed from the neck of the bladder, the irritability had so lessened that I introduced the lithotrite and caught a large piece, measuring up to seven in Weiss' instrument, and broke it and many fragments afterwards. Some of the pieces he passed were of a pale yellow colour, as if there had been deposited a layer of lithic acid on the original oxalate of lime.

Soon after this he again left the hospital, and I saw

nothing more of him till some months after for influenza fever. He had some irritability of the bladder, but nothing like his former suffering. In January last, three years since I first saw him, I had an opportunity of seeing him. With the exception of occasio a slight irritability of bladder he appeared to me to be well, following his business, and going about without any suffering. It had been a most tedious and troublesome case, in consequence of the unsteady character of the young man, and his leaving hospital before the entire removal of the fragments was completed.

In the next case the size of the stone was so great that the propriety of performing lithotryity at all might be questioned. It was at least the size of an ordinary lemon, and lithic acid—very hard therefore; and thus large and hard most difficult to break at all, and when broken the fragments, as always the case in large, hard lithic acid calculi, with sharp edges and angles. Many operations also would be required before such a stone could be got entirely rid of, that the patient would be worn out by their frequent repetition and the passage of large sharp fragments along the urethra. On the other hand a large stone is not favourable for lithotomy. The patient, moreover, was of an age, near fifty, which statistics show to be the least desirable for the operation, besides being a full, fat, pale, flabby man, nervous and anxious to the last degree, and positively bent against cutting. On careful consideration, therefore, I chose lithotryity, the operation least immediately dangerous to life; and after the stone had been broken, should the irritability be such as to forbid further operations, I would then perform lithectasy and extract the fragments through the perineum.

Case 4.—George Donnelly, ætat. 48, a stout-looking man, a farmer, complains of pain and frequency in making water; the pain chiefly after having passed it, sometimes excruciating. When passing water the stream will suddenly stop. The urine is rather pale, alkaline, and deposits a small quantity of tenacious yellow deposit—pus, gelatinized by the alkali, occasionally bloody. A stone was at once detected by a silver catheter; it appeared rather large and rough. Though the injection of water and the sounding were rather painful, the bladder was not irritable, nor had he pain in the loins or other indication of disease of the kidneys; his general health good. It appeared to me to be a case for lithotryity rather than lithotomy, the man being full and flabby, and of a very nervous temperament, and of an age the least favourable for the operation of lithotomy. The size of the stone, by measurement, larger than a hen's egg, was the only counterbalancing circumstance against lithotryity. His history was as follows:—Thirteen months ago, while sowing seed in the field, he got retention of urine, and had an instrument passed by a surgeon in the country, who declared he had stone, and afterwards passed the catheter frequently. For some time previous to the retention he had some slight difficulty in passing water, and a frequent inclination to do so. He used to suffer from pain in the left loin. About a month or so after the retention he passed near a teaspoonful of fragments of calculus, of a greyish-white colour, and evidently portions of the shell of a calculus, whether broke by the surgeon's catheter, the most probable, or spontaneously disintegrated is not certain, but they had remained sufficiently long after separation to have their sharp edges smoothed off.

July 22, 1862: I operated to-day with Weiss' strong fenestrated instrument, as the stone was so large; I caught it by the short diameter and broke it. He suffered a good deal, but was ordered a warm hip bath with a few drops of laudanum, and was soon all right again.

Aug. 4th: He passed a good deal of detritus since the last operation, and at first suffered much urinary irritation. This has now all subsided, so I introduced Weiss' lithotrite, caught a large piece, measuring an inch, broke it, and afterwards several smaller pieces. The large fragment was very hard.

Aug. 5th: He handed me a paper of detritus, and small

pieces. There was little irritation compared to that after the first operation. After this, at longer or shorter intervals, according to the amount of irritation, I operated nine times, always using Civiale's instrument, the stone during the first two operations having been reduced to fragments of such a size as I thought it strong enough to break. Its small size, the shortness after the bend, render its manipulation easier and less painful, and more ready in catching the fragments, while its scoop brings away a good deal of detritus at each withdrawal. Some of the fragments caught in these operations were very large and hard to break, and some of the pieces passed were also large. They were composed of dense lithic acid, and broke with the sharp, rather even, fracture, peculiar to that description of calculus. He fortunately had a capacious urethra, and suffered less in their passage than usual.

After the ninth operation he went to the country to attend to some farming operations, and did not return for about three months. I then got a letter from him saying he was coming to town, suffering much irritation from some piece sticking in the passage. I found two large pieces of calculus sticking in the urethra, just opposite the scrotum; I moved them forward, cut down on them, and removed them. The wound healed without any trouble, and he went to the country perfectly well. I have heard from him frequently since, as late as last Christmas. During that period, now nearly three years, he has continued quite free from the disease.

Case 5.—In October, 1863, I was asked to see a gentleman 64 years of age, who was suffering dreadful torture from a stone in the bladder; but a most serious complication of the case was an enlargement of the prostate gland to such an extent that he was unable to empty the bladder, and required to pass the gum-elastic catheter, which he had been taught to do himself, several times in the day. His sufferings increased to a degree scarcely tolerable. The desire to pass water became incessant; what little he expelled and what he drew off contained aropy bloody mucus, which he would sometimes draw out in strings on withdrawing the catheter. He was cut off from society and unable to attend to any business. He had gone to London and consulted Dr. De Mussy, by whom, as it was a surgical case, he was directed to Mr. Erichson, who sounded him, detected a stone, and recommended it to be broken. As an operation was required, the gentleman preferred to have it performed at home, and on his return sent for me. It was clearly no case for lithotomy, and by no means a good one for lithotripsy, the inflamed bladder and large prostate rendering it most unpromising. Having ascertained the presence of the stone, I injected a small quantity of tepid water into the bladder and caught the stone with Civiale's lithotrite. It was about the size of a walnut, and broke with the greatest ease. A few of the large fragments were then crushed and the instrument withdrawn, the scoop full of compressed detritus, like mortar, and composed entirely of the triple phosphate. This gentleman lived for two years and a half after I first saw him, and during that time I performed about twenty operations. After the first few operations the relief to pain and the improvement in his general health were most remarkable. He was enabled to return to his business and the ordinary avocations of life. Latterly I did not inject the bladder, but made him retain his water for some time previous to the operation. I found this plan, suggested by Mr. Thompson, to save much pain, the injection having often been the most complained of. As the state of the prostate prevented him passing the broken fragments, I took away in the spoon end of the female branch as much of the detritus as I could, but the irritability of the bladder was such that I could not pass the instrument more than twice. Some of the fragments would come away through the large catheter he passed every four hours to draw off the water. He died finally of the inflammation of the bladder, induced by the enlarged prostate, and also of diseased kidneys. I sounded him twice about a month before his death, but I could not detect any portion of stone, though such might have existed.

The operation, performed under great difficulties, did, I believe, not only alleviate his great sufferings but also prolong his life.

Cases will arise in which after lithotripsy has been performed, and the stone broken, it becomes advisable to remove the fragments by a shorter process than that afforded by further lithotritic operations.

Many years since I assisted Sir P. Crampton in performing lithotripsy on a gentleman with a very large calculus of hard lithic acid. After a great many operations, there being still several large fragments in the bladder, it appeared to Sir Philip better to remove them by the operation of lithectasy, or opening the membranous portion of the urethra from the perineum. He was led to this by the arrest of some large pieces in that situation. The result was very satisfactory. I was led to perform the same operation in the following case by the extreme irritability of the patient.

Case 6.—A man was admitted some years since into the Richmond Hospital, No. 5 Ward, labouring under the symptoms of stone in an aggravated degree, the frequency and pain in making water excessive, and much blood in the urine. A stone in the bladder was detected, and afterwards ascertained by the lithotrite to be about the size of a chestnut. He suffered much pain from the examination, the bladder being so irritable that it was evidently a bad case for lithotripsy, and yet the man, who had come from Manchester, and had worked in a manufactory there, was a still worse subject for lithotomy, scrawny, emaciated, and unhealthy-looking, his age 45. After the inflammation and irritability of the bladder had been somewhat allayed by rest in bed, hip baths, opiates, and Vichy water, I performed lithotripsy. But such irritation followed the operation, that it appeared to me a safer course to perform lithectasy, than to make further attempts to break the stone in fragments small enough to pass the urethra. I therefore made the usual incision into the membranous portion of the urethra, and having sufficiently dilated the opening with Weiss' dilator, so that I could readily introduce my finger, I tried with various kinds of forceps to catch any portions of the broken calculus; but I failed to do so, the difficulty being a very capacious bladder which the sudden emptying of urine threw into folds entangling the fragments. After gentle, though repeated, efforts, I desisted, leaving a sponge tent in the opening. For the first few days nothing but bloody, ropy mucus, the erection of the inflamed bladder, came away, but afterwards a quantity of the broken fragments and detritus. The wound in the perineum rapidly contracted and healed, and he soon after returned to England quite well.

ON THE TREATMENT OF EPILEPSY BY ARTEMISIA VULGARIS AND CARDAMINE PRATENSIS.

By Dr. O'ROURKE,

PHYSICIAN TO THE ENNISCORTHY WORKHOUSE AND FEVER HOSPITAL.

IN connection with my Report on the Treatment of Epilepsy in the Ennisclorthy workhouse, by *artemisia vulgaris* and *cardamine pratensis*, published in the *MEDICAL PRESS*, in November, 1864, I forward another containing my further experience of the cases then remaining under treatment and of those since admitted.

In my first report, Bridget Moore, marked No. 4; Anty Walsh, No. 5; Eliza Mernagh, No. 6, and William Bulger, No. 12, who remained under treatment, are all relieved; but as Mernagh did not improve much under the *artemisia* beer, she was put under the use of the *cardamine pratensis* on the 5th of May last. She is now greatly relieved, having only a slight weakness occasionally, which passes off without much observance.

A considerable change has taken place in the epileptic patients when attending at Mass. Before my treatment commenced in 1863, they were attacked in so remarkable a manner during the celebration of Mass, particularly at the Elevation of the Host, that the chaplain was obliged

to forbid their attendance. Now they are so improved that they are allowed to attend, as on feeling any approach of the attack, which they invariably do, they retire. In a minute or two it passes off unnoticed, and they return to their devotions.

I will take up the numbers from my former report, the first new case being—

Case 13.—Eliza Nolan, aged 30, imbecile, admitted on the 2nd of November, 1864, much emaciated and very feeble, and somewhat febrile, was admitted into a fever ward; had a recurrence of epileptic attacks, and was removed into the idiot wards. She was put under the artemisia beer treatment, was relieved of the fits, but died of debility on the 31st of December, 1864.

Bridget Burke, marked No. 7 in my first report, an imbecile, was re-admitted on the 1st of December, 1864; had two mild attacks after her return; was again put under treatment as formerly, and had no return of her illness for three months before she left, on the 25th of July, 1865. Her intellect was improved.

Case 14.—Sarah Sheridan, aged 51, was admitted into the idiot wards on the 7th of December, 1864, weak minded, delicate in health, ill-tempered, and easily excited; subject to epilepsy for 16 years, which was supposed to be consequent on deranged menstruation; had severe hæmatemesis before she became regular; had often fits, five or six times daily; was put under the usual beer treatment on the 6th of January last; the fits gradually ceased, and for two months previous to her leaving the house, on the 24th of April, she had no attack. Was re-admitted on the 1st of November, but scarcely ill since her re-admission.

Case 15.—Thomas Whitty, aged 60, was admitted into the idiot wards on the 10th of December, 1864; had a haggard, care-worn look; face very thin, with sunken eyes; stated he was first attacked about a year since; his fits were frequent every day and very violent; could not be induced to take the artemisia beer regularly; was going in and out of the workhouse frequently, consequently cannot be reported as under regular treatment, though he sometimes says he is relieved. His constitution is improved, and had no recurrence of his fits for five weeks.

Case 16.—James Waters, aged 50, a farm labourer, was admitted on the 12th of January, 1865; was strong and healthy, and no appearance of imbecility; had frequent epileptic attacks from his youth; could give no account of the cause; was admitted into the Infirmary for a severe injury of his hand, received in an epileptic attack. During his treatment he had seven or eight fits in the course of three days. He was removed to the idiot wards and put under the artemisia treatment; he had no recurrence of the attacks for a fortnight; had then three in one day, but the duration of the fits was shorter, and they were not so violent. For three weeks before he left, on the 6th of March, had no return, nor has he had an attack since, having been seen lately, when he enjoyed the best of health, and says he never felt himself better.

Case 17.—Mary Leavy, aged 60, was admitted into the idiot wards on the 17th of January, 1865; sallow looking and care-worn; is in very delicate health, very quiet and well-tempered, but easily excited; epileptic for some years, supposed to be caused by grief for the loss of her husband, and seeing a large quantity of blood coming from his knee, which was affected with fungus hæmatodes; was epileptic three or four times daily. After a fortnight's use of the artemisia beer she was only attacked slightly once a week. Her health is much improved; she had no recurrence of her attacks for months, except a slight weakness, which passes off without assistance. The treatment was gradually discontinued.

Case 18.—Mary Toole, aged 21, was admitted on the 15th of May last, and left on the 26th, not wishing to be confined in the idiot wards; went to service but returned on the 1st of November last; states that she has been subject to falling sickness for the last seven years, which occurred after a severe choleraic attack, brought on by the

use of improper food, which resulted in a fit or convulsions; when attacked, the fit continues for a long time before she fully recovers; while out of the house she had a severe attack, from which she did not recover for three weeks. Her appearance is staring and vacant; she is weak-minded and eccentric, temper very bad, and she is ill-disposed; her bodily health and appetite good. She was put under the usual treatment on her admission; is much relieved, as her epileptic seizures soon pass off, leaving no depressing effects.

Case 19.—Mary Magee, aged 35, an inmate for the last ten years, imbecile; of eccentric habits; was frequently an inmate of the District Lunatic Asylum in Carlow; of violent temper, and very unmanageable; was attacked with epilepsy on the 15th of June last, fits recurring seven or eight times daily; was immediately put under the usual treatment on the appearance of the first attack. Her fits are less frequent; days pass off without any. She is much relieved; has had no return for the last five weeks.

Case 20.—Eliza Furlong, aged 30, was admitted into the idiot wards on the 1st of July, 1865, as an imbecile; difficult to control, and epileptic from her birth. When more advanced in years her attacks were every month, and became more violent at each recurrence, and fits would recur every fourth hour for three or four days at each period; looks well and healthy, but temper very irritable and easily excited. She was put under the usual treatment on admission; is now much relieved; the attacks are now more like a faintness, and passes off in a few minutes.

Case 21.—Johanna Miskella, aged 18, was admitted into the idiot wards on the 14th of July last; has been an epileptic from her youth; healthy, and no way imbecile; her attacks were frequent. She was put under the usual treatment on admission. Her parents had her removed on the 30th of the said month; was partially relieved.

Case 22.—Bridget Doyle, aged 22, was admitted into the idiot wards on the 20th of July last, as an epileptic. She looks to be in good health. She attributes her first fit from having suffered much from a mammary abscess, and disappointment that her child was not taken from her by its parent, he denying its paternity; she is ill-tempered and easily excited. Her first fit was in July, 1864, and then would only have one attack in three weeks, but since her admission she has had three epileptic seizures weekly. She is now much improved, and her illness is more in the form of a weakness or faintness than of an epileptic fit.

James Duffield, aged 20, reported in my former communication as No. 11, and who, previous to his discharge, had no recurrence of his attacks for two months, was re-admitted on the 12th of August last; relapsed some time after leaving the workhouse; was again put under treatment on admission; is much improved, but not as much as when he first left; and I find that cases which cannot be kept under the continued use of the artemisia beer are more difficult to relieve on their return.

There are remaining under treatment Thomas Whitty, Mary Toole, Bridget Doyle, and James Duffield, taking the full quantity of artemisia beer, and Sarah Sheridan and Mary Magee taking the preparation only once a day. Betty Mernagh is the only one taking the eardamine prætensis, the mugwort beer having had no decided effect on her.

In most cases I find more or less relief where the treatment is persevered in; the failure is often owing to the discontinuance of the treatment or to its irregular use. When imbecility is accompanied with epilepsy, and when relief is experienced, the intellect improves and the patient gains flesh. If in private practice there be no relief in a short time, the treatment is laid aside, and hence the result is often less successful than it is in a public institution. In our Workhouse Infirmary I have the artemisia beer prepared, and never without it, and it is now one of the hospital formulæ, because there are always cases for treatment.

Your readers are aware that there are no cells or wards for the proper treatment of lunatics in the workhouses of

Ireland, therefore I had no opportunity of judging the effect of the artemisia beer on dangerous lunatics whose illness was accompanied with epilepsy. We had one case, James Nolan, but being a dangerous lunatic, he had to be committed to Wexford Gaol on the 1st of October, 1862, and is, I understand, there still.

I have tried all the medicines that are most recommended for the relief or cure of epilepsy with little advantage, and have used gallons of the recent juice of the cotyledon umbilicus without even temporary effect. The only relief I found to be produced was by the use of the "Decoct. Aloes Comp."—the "Polv. Aloes c. Cannilla," in medicated waters, before I began the use of the artemisia beer. It is not necessary to have the latter prepared by an apothecary, as any careful nurse or wardsmaid can have it properly boiled, only to be careful of the directions and quantities, and have the plant in proper season and condition.

The last Census Report shows that 222 deaths occurred from epilepsy in lunatic asylums, and 619 in workhouses, in the ten years ending 1861, and I see that 96 died in the workhouses in the year ended September, 1864. In each class of these institutions there is unfortunately an opportunity of testing the effect of these two medicines, which with me have produced the results stated in my paper of the 23rd of November, 1864, and in that I now send, and I trust we shall have the reports of several of the medical officers of these institutions on the subject. Hitherto I have only seen one, from Dr. Edmondson of Clonmel, published in the MEDICAL PRESS of the 22nd of March last. Dr. E. states that he put three females and two males under the treatment described in my paper; that in one female the fits ceased from the 10th of December, but recurred on the 24th of January, and have continued with their accustomed frequency. Dr. E. does not state how long this patient was under treatment, nor whether on the recurrence of the attacks he resumed the medicine. Of the effect on the other two females he gives no account, nor how long he continued the medicine with respect to the two male cases. Dr. E. observes that he continued the medicine for fourteen weeks without producing the slightest effect, but that, as they did not take it regularly, it would be unfair to record the results. As there are thirty-five epileptics in his asylum, it is to be hoped that Dr. E. will not be disheartened by his want of success in these cases, but that he will give a fair trial to the medicine, which in other hands has had more success than in his. Even though mugwort were not permanently curative in its action, and that it only affords, in more or less instances temporary relief, it would still be a valuable remedy. But that it is capable of more, the relief experienced, by Peter Brien, the ninth case in former report, is a satisfactory proof, without reference to the benefit derived by other epileptics. I agree fully with Dr. E., that we should record the failures as well as the successful cases, and I have honestly done so.

Enniscorthy, December 30, 1865.

PROCEEDINGS OF SOCIETIES.

SURGICAL SOCIETY OF IRELAND.

Dr. WILMOT, President of the College, in the Chair.

THE first meeting of the Surgical Society for the present Session was held on Friday, December 8th, in the Albert Hall, Royal College of Surgeons.

The PRESIDENT delivered the Inaugural Address, which appeared in THE MEDICAL PRESS of December 27, 1865.

Dr. BEATTY said: I trust you will, for a few moments, excuse one of the band of 1831 who formed the Surgical Society, and who has from that day to this looked upon it with the regard and affection which it deserves from every member of the medical and surgical profession in this country. I take the liberty, on the present occasion,

of expressing what I know you all feel, what I very deeply feel, the value of the address with which the President has just now honoured us. I have heard every address that has been delivered from that chair since its foundation, and I think those who are about me (and they are not many) who did assist us in the foundation of the Society, will agree with me in saying that we never were favoured with an address more comprehensive, more valuable, more to the point, more feeling, and one better deserving to be carried away in the memory of every one who heard it. It is characterised by all the qualities that are inherent in the President, sound judgment, good taste, learning, and an elegance of style which is peculiar to himself—unassuming, yet strong; modest, yet firm, in every respect what an address ought to be, addressed to an assembly such as the present. The Surgical Society has done good work, and I have no doubt whatever that, in the hands of the able President who now fills the chair of the College of Surgeons, it will go on and prosper, and be a credit to the country, and uphold Irish surgeons throughout the world as it has hitherto done.

Dr. HARGRAVE had the greatest pleasure in adding his testimony to that of Dr. Beatty. He, like Dr. Beatty, was one of the band which founded that Society, and it was a great pleasure to him to see its triumphant success. He well remembered that when first formed, the greatest doubts as to its success were entertained on the subject, but happily they had not been realized. It was said that the debates might lead to ill feeling; but, although there had been many warm discussions at their meetings, he did not think they had ever left unkind or unpleasant feelings in the minds of the members (hear). He had the great pleasure in bearing testimony to the value of the President's address.

Dr. BENSON said, that as one of the originators of the Society, he also wished to add his testimony to that of the gentlemen who had preceded him. Like Dr. Beatty, he had heard every introductory address, and, perhaps, every concluding address that had been delivered in that society, and for upwards of twenty years he had been one of its secretaries; and he did not recollect to have ever heard, more appropriate or suitable remarks than those delivered on the present occasion. The words of the poet occurred to him as an apt description of the address—

Though deep, yet clear; though gentle, yet not dull;
Stro g. without rage; without o'erflowing, full.
—(Applause.)

The PRESIDENT said he was extremely obliged to his kind friends for the approval which they had expressed of his address, which, to tell them candidly, he thought perfectly unworthy of the present assembly. He was more atterred than he could express, for there were not three men of whose opinion he could think more highly of than his friends, Dr. Beatty, Dr. Hargrave, and Dr. Benson.

CASE OF MALIGNANT TUMOUR FILLING THE ENTIRE MOUTH AND FAUCES.

Mr. TUFNELL said he hoped the case which he was about to bring forward would be one of interest to the Society and of use to its members. It was a case of rarity, fortunately, for he believed that operative surgery in similar cases, beyond the prolongation of life, would be found unavailing. The case was that of a recurrent malignant tumour filling the fauces, the posterior nares, passing down the pharynx to the œsophagus, and filling the mouth so completely as to project for some distance beyond the teeth. It occurred in a girl only seven years of age. This child in February last was taken to Dr. Halpin of Arklow, who found the posterior nares plugged up with a fungous growth, and he recommended that the child should be taken to the county infirmary, with a view of its being properly fed and supported, as its mother was in great want and could not properly attend to the child. This was done. Dr. Nolan, the Surgeon of the Infirmary, removed the tumour, and the child for a time did well. The tumour recurred again, and a second time Dr. Nolan

removed it. The child was then brought to its home. Upon the 7th of July last the child came under his (Mr. Tufnell's care) in the City of Dublin Hospital. The condition then presented was the following:—Upon opening the mouth a fungoid tumour was visible, which nearly projected as far as the incisor teeth. Passing the finger backwards as far as the child would allow, the fungoid growth could be felt passing downward into the pharynx, but beyond this no further examination could be made. During the day time and whilst awake the child breathed pretty well; but the moment sleep set in, and the child became unconscious, asphyxia threatened, and it woke up with a sudden start. Upon consultation, it was considered possible by means of a firm wire *écraseur* to cut its attachment away. The child being well under the influence of chloroform, so that the mouth might be fully opened, upon the 25th of July an attempt was made to carry out this operation. The child was brought under the influence of chloroform very favourably, but upon opening the mouth, became asphyxiated, and was evidently dying, the case apparently being one of chloroform accident. Artificial respiration by means of Sylvester's method was resorted to, and the galvanic battery used. After a little time the child recovered. In the evening, reflecting over the case, Mr. Tufnell considered that this was not a chloroform accident, but that it had arisen from alteration in the position of the tumour. On the day afterwards this was tested by placing the child seated in the lap of the resident, the lower jaw was then simply depressed, and in fourteen seconds the child ceased to breathe. It being necessary that operative proceedings should be resorted to without delay, upon the 28th of July a second attempt was made to remove the growth rapidly without the influence of chloroform, with the assistance of an apparatus of Dr. L'Estange's for forcing the mouth open, and thus enable the wire to be got round the tumour at once. On attempting to do so, however, the child became asphyxiated a second time, and it was evident that nothing could be effected without the previous intervention of tracheotomy. That operation was consequently immediately performed, and the patient returned to bed. The trachea tube was used, two semicircular portions of the trachea being taken out, as recommended by the late Professor Porter. It was necessary, however, that some tube should be afterwards worn. The first introduced was of the ordinary character, but to this there were two objections; firstly, from the conical shape there was great difficulty in keeping it in; and, secondly, its sharp edge irritated the parts. Mr. Tufnell, therefore, substituted a piece of No. 12 gum-elastic catheter. After the child had become accustomed to the use of the tube, the question arose as to a third interference; but the emaciation and weakness were so great that no hope of recovery could be entertained. After death the body was examined, and the preparation exhibited was made. Prior to death there had been several hæmorrhages from the tumour, and it had since greatly contracted, assisted by the spirit in which it had been placed, but whilst the child was living it projected fully half an inch beyond the margin of the teeth. It was found to spring from the left side of the soft palate and thence filled the whole mouth. Posteriorly it passed upwards to the base of the sphenoid bone, filling the posterior nares, and then passing down into the œsophagus, distended it. The œsophagus, owing, no doubt, to the child having been for a long time fed by the rectum, was greatly contracted, and barely able to admit a No. 7 bougie. The tumour, having been microscopically investigated by Mr. John Barker, Curator of the College of Surgeons, was reported to be fungus hæmatodes in its early stage. The lungs of the child were examined and found to be healthy. Mr. Tufnell had endeavoured to find if the child had ever received any injury, such as a scald in the mouth, but no cause for the origin of the disease was given.

Mr. COLLIS said that some two or three years ago a

man, upwards of 80 years of age, came to him at the Meath Hospital suffering from cancer of the tonsil—an unusual situation for such a disease. It had grown forwards and inwards, so as to press on the orifice of the glottis, so much so, that the man was frequently threatened with suffocation when he attempted to swallow. The upper movement of the glottis brought it in contact with the tumour, and fits of suffocation were the result. On two occasions, he (Mr. Collis) removed as much as he could of the tumour, and with temporary, but only temporary, relief to the patient. The patient came to him twice at intervals of two months, and on each occasion a similar operation was performed. He presumed that the man died shortly afterwards, for he had not seen him since, and he was at least 84 years of age.

Mr. STAPLETON observed that, as to the late Mr. Porter's particular method of performing the operation of tracheotomy, as that gentleman was the first to publish it, he was entitled to the credit of it; but he (Mr. S.) had been for a great many years teaching that it was necessary to perform the operation in that way. He thought the best way, particularly in children, to perform the operation was by catching the part with double hooks and cutting the piece out with a curved scissors. Although this was an easy operation on the dead subject it was a very difficult one on the living, and particularly on the young subject, and the amount of the difficulty could hardly be appreciated by one who had not performed it. Instances had occurred where, by the slipping of the knife, the carotid artery had been penetrated. Therefore he thought the best way, as he had stated, was to seize the trachea by means of hooks and cut out a circular piece with a curved scissors. He perfectly agreed with Mr. Tufnell in what he had said about tracheal tubes. He thought the blunt end of a catheter was borne better than the silver instrument. Some years ago he had a case of a tumour in the mouth, which was a very interesting one, and had passed through more hands than his. It was first under the care of Mr. O'Reilly, who extirpated the tumour, which grew from one side of the palate, and the girl appeared to be well for *five or six months*. It then grew on the opposite side, and another surgeon removed a considerable portion of it. Again it grew, and it then came under his care, and he, too, thought he was equally successful. He removed the growth, and a cicatrix formed in the soft palate. Shortly afterwards it grew again, and was removed by the *écraseur* several times. It was also removed by the hot wire heated by galvanism. Each time it grew deeper and deeper, and was pressing more on the organs of respiration. Towards the end, a portion as large as a small orange could be observed, and in two days afterwards it was nearly as large as ever. There was no hæmorrhage from the tumour, when removed by the heated wire. The poor girl at last lost courage and returned to the country, where she died, partly from inanition and partly from asphyxia. This tumour could not be called fungus hæmatodes. It was a hard fibrous growth, and the rapidity with which it grew was another interesting feature. He was assisted by Dr. R. McDonnell, who brought a powerful galvanic cautery, which acted to perfection with the greatest rapidity and without the slightest hæmorrhage or pain.

Dr. HARGRAVE said that no more relief could be given to the patient in the present case than had been given by Mr. Tufnell in performing the operation of tracheotomy. The child recovered from it very rapidly. There was one operation that might have been attempted. By dividing the lower jaw they might have got a view of the tumour and removed it, but that was an operation which was not justified under the circumstances. He had paid great attention to the operation of tracheotomy, and had performed it seven or eight times. In some respects he thought it the most difficult operation in surgery, whether by day or by night, for on some occasions the surgeon was working against time, and the whole object was to get through the superincumbent tissues and let in the atmo-

spheric air. In these extreme cases what should the surgeon do? If he passed his finger into the wound and pressed down everything to the chest he could plunge his knife into the trachea and pass it upwards without the slightest risk. By pressing the trachea it was rendered fixed, and the operation could be effected in the safest manner. As to these tracheal tubes he thought they were the worst things ever introduced into operative surgery. If a tracheal tube were wanted the best they could adopt was the section of a catheter used by Mr. Tufnell.

Mr. STAPLETON observed that a very able surgeon now no more, the late Dr. Power, had more than once assisted him in performing this operation, and he agreed with him that the best way was not by raising up the trachea—that was not what he said—but by grasping it in the manner already described. It was not an easy operation; the moment you cut it from below upwards you take an elliptical piece out, and as soon as the lungs expand, and there was sufficient air, there was no danger of hæmorrhage. The great point was not to be in a hurry. It was an operation that required the greatest coolness. No one could have an idea of the depth of the trachea in a young child even, and the younger the child the more difficult was the operation for the greater the depth, he should say, the greater the danger from venous hæmorrhage.

Dr. DUKE wished to mention a case in which he had to perform the operation of tracheotomy, about a year and a half ago, under urgent circumstances. The subject was a gentleman past 60 years of age, a large man, but not very fleshy; was choking; his face livid; from attempting to swallow a piece of meat. On passing his finger down the throat he could barely touch the meat with his nail. He had a pocket case with him from which he took a scalpel, and without being very particular as to what veins he might wound, he plunged it into the trachea and made an opening, which was followed by relief. He kept the blade of the knife in the trachea until he obtained assistance. He sent for a probang, with which he dislodged the meat, and then the natural respiration was established. He then closed the orifice and brought the edges of the wound together. There was not a single bad symptom, the wound healed rapidly, and the patient got completely well. The only inconvenience he suffered being retention of urine for some days, owing, no doubt, to the shock to his system.

Mr. TUFNELL observed that if the case he had brought forward should lead to the discontinuance of tracheal tubes, as a general rule, he thought the evening would be well spent.

Dr. HANS IRVINE hoped it would not be understood that tracheotomy was the only operation to be resorted to. There was another operation which could be easily performed, and as quite as effectual—laryngotomy, which he thought would have been suitable in his friend Dr. Duke's case.

Dr. JAMESON said he had performed the operation twelve times for the one cause, the scalding of children by boiling water. They all knew the difficulty of performing it with young children, from the depth of the parts and the rapidity of motion of the trachea. He himself always seized the trachea with a small double hook, and with curved scissors cut out a circular piece, and never used a tracheal tube. He took care the line of the incision should be medial, and the aperture into the trachea central with that, so that there was no danger of the parts overlapping.

Mr. CROLY said while he was resident surgeon in the City of Dublin Hospital, a patient there was suddenly seized with intense difficulty of breathing. He was about opening the trachea when Dr. Geoghegan, under whose care the patient was, came in and performed the operation. It was utterly impossible that the man could live if the tube were introduced, and Dr. Geoghegan put his mouth down to the wound and sucked the trachea on several occasions. They were obliged to do so for an hour, in the ward, to save the patient's life. In such a case as that,

the tube would be perfectly useless, and must have choked the patient.

Mr. FLEMING observed that Dr. Irvine had started an important point. Unquestionably, in such a case as that mentioned by Dr. Duke, it was more than probable, if there were sufficient leisure, that the operation of laryngotomy would have been feasible, and likely to be productive of as much benefit as tracheotomy. On one occasion in the public streets a child was attacked with extreme dyspnoea, and was in danger of death from suffocation by choking. Sir Philip Crampton was riding by, and he used as a probang a little riding whip which he had, and saved the life of the individual. A somewhat similar thing once happened to himself. At the Royal Dublin Society the son of a respectable professional man in this city was playing with a penny, and it slipped back into the pharynx. He was in immediate danger of suffocation. An attempt was made by one of our best surgeons to remove the foreign body, but it failed, and death was impending, when under the circumstances he (Dr. Fleming) had recourse to a small piece of switch, and down went the penny into the stomach, and he subsequently learned that it passed along the tract of the intestines after three weeks' delay. He did not reflect on the treatment adopted by Dr. Duke; but he thought, if they were satisfied that the obstruction was caused by a foreign body, and that it was at the commencement of the œsophagus, recourse should be had to mechanical means to send that body into the stomach. As to the provisions requisite in cases of tracheotomy, it would be in the recollection of some present that at the period when he commenced his professional studies the leading men of that day had not recourse to any tubes.

Mr. HAMILTON said that he had been obliged to perform the operation of tracheotomy in the case of a man who was affected with syphilitic laryngitis. When he left the hospital he would not allow the tube to be removed. He went to work at his usual occupation, and on one occasion took out the tube and cleaned it, and in his hurry, when returning the tube, he lacerated the posterior portion of the trachea and died.

Mr. STAPLETON observed that very often, when people were choking, the jaw became locked, and it was impossible almost to open the mouth.

The meeting then adjourned.

MEDICAL SOCIETY OF LONDON.

MONDAY, DEC. 18, 1865.

Mr. I. B. BROWN, President.

THE meeting was very largely attended by members of the Society and visitors, the numbers present indeed exceeding the capacity of the room for accommodation. Most of the well-known syphilographers of the metropolis were present.

TERTIARY SYPHILITIC ULCERATION.

Mr. HENRY SMITH showed a patient who had suffered from a very severe form of tertiary ulceration of the skin and bones of the face, and whom he had cured by larger doses of iodide of potassium than he believed were generally used.

Mr. WALTER COULSON referred to similar cases.

OVARIOTOMY.

Mr. BAKER BROWN showed an Ovarian Tumour that day removed, the pedicle having been seared by the actual cautery, used after the manner which he had lately introduced. He had now operated in sixteen cases, using the actual cautery, and in fourteen of them with success.

SYPHILIZATION.

Mr. JAMES LANE stated that he was not yet in a position to make a formal communication on the subject of syphilization. It was his intention merely to offer a few remarks, chiefly clinical in their character, on the cases which had been under treatment by Professor Boeck in

the Lock Hospital, in order to afford him an opportunity of taking part in a public discussion on the subject before he left this country. But for this he should have considered it premature to bring the subject forward, sufficient time not having elapsed to enable him to form any definite conclusion on the value of syphilization as a curative measure. He was anxious, therefore, to have it understood that for the present he declined expressing an opinion on that point, and that as yet he was neither an advocate nor an opponent of the method. They were told by Dr. Boeck that by means of syphilization, properly carried out, constitutional syphilis could be completely and permanently cured, and that relapses, which were unfortunately so frequent after mercurial and other treatment, would not occur at all, or would be so slight in degree as to be of little or no importance. Therefore in proportion as syphilization became generally practised, might there be expected to be a diminution of all the most serious and destructive consequences of the disease. To assist in the solution of these important questions, he had, in conjunction with his colleague, Mr. Gascoyen, offered to place the in-patients of the Lock Hospital at the disposal of Dr. Boeck, in order that Dr. Boeck might conduct the treatment under their supervision, and that they might in due course report upon the result from their own observations.

Twenty-one cases had been under treatment by Dr. Boeck during the last four months. Sixteen of these had been well-marked examples of secondary syphilis, uninterfered with by any previous mercurial treatment. Four had been cases of secondary disease previously treated by mercury, and one was a very severe tertiary case. Dr. Boeck had been desirous of confining himself as much as possible to non-mercurialized patients, as affording the best illustration of the value of the treatment, having found that a previous mercurial course interfered materially with the regular progress of the inoculations, and with the permanence of the result.

Mr. Lane then gave a brief account of one of the cases which had been longest under treatment. The patient was a girl, aged eighteen, with mucous tubercles and a well-developed squamous eruption. She was admitted into the Lock Hospital in August last, having undergone no previous treatment whatever. The inoculations were commenced by Dr. Boeck on the 5th of September with matter from a non-indurated sore, two punctures being made on each side of the chest. The inoculations were repeated sixteen times in this region of the body at intervals of three days, the matter being taken each time from the inoculations immediately preceding. The resulting pustules became smaller by degrees, and at last failed altogether. A like process was then (Oct. 26th) commenced upon the arms with fresh matter, and proceeded with there till Nov. 19th, when the inoculations failed. The same thing was then done on the thighs, and has been persevered with there to the present time (Dec. 18th); fresh matter, however, having been several times required. Punctures have also been made several times on the arms with matter from the thighs, with positive results. The treatment of this case might be considered as nearly but not quite concluded, it having extended over a period of three months and thirteen days. She is now evidently losing the susceptibility to receive the poison by inoculation, and latterly, as that susceptibility has diminished, her symptoms have been rapidly disappearing.

A second case was alluded to, the treatment of which Dr. Boeck considered to be now concluded. In this case all the original symptoms had disappeared, and the immunity to inoculation with fresh matter was nearly if not quite complete. The important question of relapse of course remains to be decided.

Mr. Lane stated that in none of the cases had there been any spreading ulceration at the seat of the inoculations. The earlier sores seldom exceeded half an inch in diameter, the majority, especially the later ones, having been much smaller than this. Their average duration had appeared to be about three weeks. The health of the

patients had, in most instances, improved under the treatment; in none had there been any deterioration. The disappearance of the original symptoms, it seemed, could not be expected till towards the end of the treatment. On the contrary, a fresh accession of symptoms had been several times observed, and, in one patient, a severe attack of iritis. The inoculations, however, were persevered with notwithstanding. The patient with iritis had recovered in about the usual time without any permanent damage to her eye.

After alluding to some further details, Mr. Lane said there was one point of great interest which these experiments had served to illustrate. The inoculations had been practised with matter derived from indurated as well as from non-indurated sores. Matter from patients undergoing syphilization, but originally derived from an indurated sore, had been sent from Norway by Dr. Bidentkap, and had been inoculated on several of the patients in the Lock Hospital, with no appreciable difference in the size or appearance of the resulting pustules. Matter derived from a well-marked indurated sore in an out-patient of Mr. Walter Coulson had also been inoculated on one of the female patients, and well-developed pustules had resulted, from which many re-inoculations had been made. The conclusion to be drawn from this fact was obviously adverse to the theory that had been put forward of late years—that matter from an indurated sore could not be inoculated upon another individual already the subject of syphilis.

In conclusion, Mr. Lane said that, although he and his colleagues had not yet sufficient evidence to enable them to form an opinion as to the curative power of syphilization, they had seen quite enough to induce them to consider the investigation of great interest and importance, and fully intended to pursue it as suitable cases came before them. His association with Dr. Boeck had inspired him with a profound respect for that gentleman's scientific attainments, as well as for his straightforward and truthful character; and he felt certain that in leaving England he would carry with him the good wishes and the sincere esteem of all with whom he had come in contact.

Dr. DRYSDALE had had the permission of Mr. Lane to watch the progress of the interesting series of cases treated recently by Prof. Boeck at the Female Lock Hospital, and he thought that these experiments were pregnant with interest. As observed recently by Mr. de Méric, at a meeting of the Harveian Society, there could be little doubt that the idea of treating syphilis by inoculation arose from the fact that many medical men were most averse to prescribing mercury for the disease. He (Dr. Drysdale) certainly agreed in this view of the matter, and he could add that he knew, from conversation with Prof. Boeck, that that gentleman had observed that syphilis when treated with mercury became a most intractable complaint, whilst when treated by common, sound surgical methods it usually was a benignant disease, although not invariably so. Furthermore Dr. Boeck had said, frequently, that when cases had already been treated by mercury there was a certain *facies* by which he could recognise them, and that such cases did not benefit so much by the inoculation of fresh virus as others treated by hygiene, &c. Many medical men were apt to attach little importance to the doctrine with regard to mercury in syphilis, which they seemed to consider a subject fit to be decided by so-called specialists. Nothing could be a greater delusion. The six months' course of mercury prescribed by the renowned Ricord for indurated sores was the Malakóff of the empirical school, and was, in his opinion, the greatest blot in the modern practice of medicine. An example of the bad effects of the mercurial treatment had just been shown to the Society by Mr. Henry Smith. It was easy to see how long the poor man had been treated by mercury. Of the cases treated by Dr. Boeck, he (Dr. Drysdale) had made some notes. There were the cases of two women, one with severe rupia and ulcers on the lower extremities, which the Doctor had treated for some time by inoculations without any one of them rising. Finally, however, they did take, and seemingly

to the manifest advantage of both patients. Although this of course was, like most other medical sequences, a case of *post hoc*, was it *propter hoc*? In the other 18 cases of young women treated by inoculation of the virus, he had not thought that the eruptions seemed to fade much more rapidly than when treated either by expectation, or, what was much better in many cases, the use of hot-air baths, careful diet, &c. One young girl of the eighteen had iritis, and he would call the attention of specialists in ophthalmic medicine—for this was a medical, not a surgical question—to the fact that the patient was treated in the most simple manner possible, and yet recovered completely. On the whole, although he had not seen sufficient of the practice of syphilization to make him a great partizan of this method over that of rational treatment by the ordinary non-specific plan used in other diseases, he had not seen any damage done by the inoculations; no phagedena had appeared, and the pain was almost nil. Altogether it was infinitely less objectionable than Ricord's plan, and perhaps it might be a positive therapeutic agent, as well as a method of putting away mercury.

Mr. R. W. DUNN stated that through the extreme kindness of Prof. Boeck he had been enabled to watch a case in private practice treated by syphilization. Prof. Boeck commenced his treatment on Oct. 27th, and had from that time regularly attended. When Dr Boeck first saw the patient she was in a very low weak state, not able to retain anything on her stomach. She was so ill that he (Mr. Dunn) did not think she could recover, having large sloughing ulcers on her legs, feet, head, and face, and rupia, more or less, over the whole body. At first the inoculations did not take well, but as soon as they commenced to take, her condition began to improve. The ulcers put on a healthy appearance, her appetite returned, and her health improved in every respect. At present nearly all the ulcers are healed. Her appetite is good, and her general health very much better. Previous to the syphilization she had been treated by iodide of potash, steel, bark, chlorate of potash and opium; no mercury had been given. During Prof. Boeck's treatment the only medicine she took was some bismuth and effervescent medicine to allay the sickness, and opium at night to allay pain and promote rest. This woman when she was first syphilized was in a worse condition than the worst case treated at the Lock Hospital by Prof. Boeck. He (Mr. Dunn) intended to pursue the same treatment in this case after Prof. Boeck had left, and hoped at some future period to be in a condition to report to the Society a successful termination of the case.

Mr. DE MERIC said he had been anxious to hear Mr. Lane's paper, with the hope of becoming acquainted with some definite conclusions as to syphilization; but it was plain that the surgeons of the Lock Hospital were not as yet prepared to pledge themselves, and we must wait for the report which Mr. Lane had promised. He (Mr. de Méric) had been an antagonist of syphilization for the last twelve years. He was sorry to be obliged, in the presence of Professor Boeck, to offer a few strictures on this practice. He was sorry, because he held in very great esteem the scientific attainments of the Professor, and highly valued the services which he had rendered by his patient and extremely valuable investigations in syphilis and skin diseases. Indeed, the men who had practised syphilization were all men of worth and standing; as Sperino of Turin, Boeck, Bidentkap, and others. But, though highly estimable, they were nevertheless mistaken, because the practice must be condemned, whether it be considered in an experimental, a therapeutical, or a moral point of view. As an experiment, the successive inoculations of the matter of chancre, from various sources and from various species, were extremely interesting; the pathologist could only gain by observing the transformations, and might perhaps be led to the discovery of some great pathological principle. But the patients thus operated on would not gain by these proceedings; the possible results just pointed out were too dearly

bought; and he (Mr. de Meric) thought—though he had himself inoculated on a comparatively small scale—that we were not justified in indulging in hundredfold inoculations upon the same subject. In a therapeutical point of view, he considered that syphilization was quite nugatory. Dualists would at once condemn it; because they would justly answer that inoculating the matter of soft chancres had no effect on the disease diffused through the whole organism; and that, even where the operators succeeded, by dint of irritation, in inoculating the matter of hard chancres, the results were simply the phenomena of the soft sore. But even unicists might say that a patient suffered from generalized syphilis by his own peculiar receptiveness; and how could those who practise syphilization hope to act upon this peculiarity by inoculating a number of chancres? Unicists knew, in spite of their belief in one virus, how difficult it was to inoculate a hard chancre upon a syphilitic patient; therefore, seeing the ease with which soft sores could be multiplied, they must admit the inability of the latter to act upon the disease. When they saw the secondary eruptions fading during the successive inoculations they could not help recollecting that such eruptions might also fade without any treatment whatever, as shown by the non-mercurialists. Therapeutically, the patients were therefore no gainers, and were tortured to no purpose. In a moral point of view, the speaker contended that the practice was highly improper. It was not fair, he considered, to tattoo patients in this manner, and mark them for life; it was not right to introduce a morbid poison a thousandfold into human organisms. The practice might even have a demoralizing effect, especially upon the girls operated on. Mr. de Meric concluded by declaring immunity a myth; by adducing statistics (taken from Dr. Boeck's own works) damaging to the cause of syphilization; and by hoping that the Professor would some day frankly own his error.

Professor BOECK said—As medical men, and studying the natural sciences in general, we must observe Nature, and from these observations draw our conclusions. Whether the results be or be not agreeable to us is a secondary question: it must be truth in the first place, and truth only. So also with our observations on syphilization. Here we have a series of phenomena which are quite new. The first thing we observe is that, if we continue our inoculations with the syphilitic virus, the organism gradually becomes insusceptible to this virus. This is an important fact, with which I have been extremely struck, and which showed me that I had before me a thing which ought to be studied. At the same time, when we have obtained this immunity, we have also a healthy individual before us. This fact cannot be denied; we see it every day, and it must strike every scientific physician in the highest degree. But this immunity does not exist, says Mr. de Méric. This objection has been made before. Thirteen years' experience, however, has shown me that I in every case attain this immunity. Another question is, how long will this immunity last? It is true that after a shorter or a longer time we obtain a pustule. This pustule, however, is ordinarily small, and the sore also. And if, again, we inoculate from this pustule, then we shall have on'y a very short series of inoculations. I will explain, however, in another manner the state which is obtained by continued inoculations. The organism, with regard to the syphilitic virus, never comes back to the same state in which it was before syphilization. I presume it is a well-known fact that it is not seldom the case that, a week after the first vaccination, by the second vaccination we obtain another little pustule, and that most of the individuals, after a number of years, are no more insusceptible. Therefore I can, as to vaccination, also ask the question, where is the immunity? With regard to children born by syphilized women, the same result takes place as after the mercurial treatment—that is, when the woman has been syphilitic, the first child, according to the rule, is syphilitic; when the man has been syphilitic, as a rule, the children are healthy. Mr. de

Méric gives statistics for the different methods of treatment from my published works. We have more recent data from Dr. Biedenkap's memoirs. But I take the numbers as they are given by Mr. de Méric. In my opinion it matters little whether the treatment requires some days more or less; it also matters little whether a new rash appears. It is of more consequence when the relapse is connected with loss of the nose, as we have seen in the patient this evening presented before the Society. The principal thing to ascertain, however, is that the interior organs are not affected—the nervous system, the liver, the kidneys. The study of these internal syphilitic diseases is yet in its infancy; but in several hospitals in London I have seen such diseases, which have been shown to me as of syphilitic origin. This evening the different kinds of chancre have been spoken of. My experiments in the treatment by syphilization have made me a unitist. It would be out of place to discuss this point now. I shall only make one observation, which, I think, is convincing. My colleague, Dr. Biedenkap, has every day during a fortnight inoculated from an indurated chancre the man himself on both his sides, but without effect. Subsequently he irritated the chancre with savin powder, and then, when the matter had become purulent, he had a positive result by the inoculation, papules having been developed at the sites of the former inoculations. These papules were covered with crusts, and were of the same appearance as those which occur on healthy persons after inoculation from secondary symptoms. (These inoculations, as you know, have principally been made in Germany; I have never practised them.) As to the question, how does syphilization act? I answer I do not know; but if you will have my theory I will give it. The syphilitic disease tends to go through a certain course, and does so very often when we let it alone, without any medicine. But often Nature cannot help herself in these chronic diseases, as we have many relapses. Mercury will arrest in a short time the development of the disease on the skin and on the mucous membranes. But is this desirable? I believe not. When the disease cannot go through its own natural course, the interior organs are very easily affected. By syphilization I help Nature. Now, we come to another point—the immorality of the treatment. Here I stop; I have no answer, because I cannot understand the meaning of it. I cannot conceive how it can be immoral to apply on the skin a matter which already flows in every drop of blood. Mr. de Méric has shown that I have changed my opinion with regard to the nature of the radesyge. This is true. I hope Mr. de Méric will follow my example, and when he is convinced that syphilization is not immoral he will avow it frankly.

Mr. J. LANE, in reply, said he thought the discussion which had taken place could not fail to be satisfactory to Prof. Boeck. The opponents of the practice of syphilization had been represented by Mr. de Méric, who was as well able as any one in that room to do justice to any case which he took up. The result must be considered favourable to syphilization, if no more solid arguments could be brought against it than those which they had heard from Mr. de Méric. Its true value, however, could only be settled by time and by experience; and till the proper time arrived he wished himself to preserve a strict neutrality in the matter. Mr. de Méric had been disappointed that the officers of the Lock Hospital had not brought forward something more tangible; but would he not have had much more occasion to find fault with them if they had, with the imperfect data they at present possessed, come down with hastily-formed conclusions, which must have been practically valueless on one side or the other? It had been urged, among other objections to inoculation, that we do not know how it acts, or what remotely injurious influences may arise from it. The objection might be urged with equal force against almost every remedy in common use. Do we know how quinine acts? And might we not equally refrain from experimenting with every new re-

medy, for fear it might have some remote and mysterious influence on the system? Mr. de Méric had commiserated the patients subjected to syphilization. He (Mr. Lane) could only say that none of them had been so treated without their own deliberate consent after the matter had been fully explained to them. None of them had wished to have the treatment discontinued. In several it had been undertaken by their own express wish. The treatment, in fact, was not nearly so severe as might be supposed. They had also been told that syphilization was immoral. It would have been more to the point if they had been told how, or why, or wherefore it was immoral; for without further enlightenment, he, for one, was altogether unable to conceive how morality could have anything to do with it one way or the other. It was an *ad captandam* argument which, he thought, would hardly have been employed if more weighty ones could have been found. The question which these experiments had been undertaken to decide was, whether syphilization could do what it professed. If it could, he believed it would confer a great benefit upon the community. It might be that it would not entirely prevent relapses—that they would still occur in a certain proportion of cases; but the *quality* as well as the *quantity* of the relapses must be taken into consideration. After syphilization the relapses, it was said, are so trifling in degree as to be of no importance, while they must all know from sad experience what they sometimes come to after the ordinary methods of treatment.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, DEC. 5, 1865.

Dr. PEACOCK, President.

Dr. RAMSKILL showed

A HEART WITH RUPTURE OF THE LEFT VENTRICLE, from a lady of mature years, occurring soon after taking food, the heart being in a state of fatty degeneration. The coronary arteries were not diseased, nor were the valves. The rupture of the heart was preceded by pain, referred to the epigastrium, in the morning of the day on which she died. After the access of this pain she had dressed herself and taken food. Her death took place in the evening.

Mr. CALLENDER exhibited the parts removed at an

EXCISION OF THE KNEE,

in a child seven years of age. There had been partial dislocation of the knee. The femur was so soft that it was broken at the operation by the assistant in flexing the knee. This caused more shortening after recovery than would otherwise have taken place.

Mr. CALLENDER also showed a specimen of recent Fracture of the Carpal End of the Radius, with Fracture of the Styloid Process of the Ulna and Fracture of the Scapoid Bone.

The PRESIDENT introduced a specimen of

DISSECTING ANEURISM OF THE AORTA.

The first symptoms occurred a week before death. There was great ecchymosis of blood in the posterior mediastinum, considerably compressing the lung, but not bursting into the pleura. The coats of the carotid artery were separated from each other, and there was another opening near the root of the left subclavian artery. This was the only case on record where the rupture extended into the mediastinum, instead of into the pleura or pericardium as usual.

ACCIDENT TO DR. ALLSBORN, EDINBURGH.—On Thursday evening last a serious collision took place at the St. Margaret Station of the North British Railway, by which several passengers were dangerously hurt, including Dr. Allsborn of Princes-street, who was injured about the head, and is still in a precarious condition from the accident.

REVIEWS.

MANUAL OF MATERIA MEDICA AND THERAPEUTICS: being an Abridgment of the late Dr. Pereira's Elements of Materia Medica arranged in conformity with the British Pharmacopœia, and adapted to the use of Medical Practitioners, Chemists and Druggists, Medical and Pharmaceutical Students, &c. By FREDERICK JOHN FARRE, M.D. Cantab., F.L.S., &c., assisted by ROBERT BENTLEY, M.R.C.S., F.L.S., &c., and by ROBERT WARINGTON, F.R.S., F.C.S., &c. London: Longman, Green, and Co. 1865. Pp. 614.

ALTHOUGH since the publication of the British Pharmacopœia many excellent works have been published on the Materia Medica and Therapeutics, yet by none has the present volume been surpassed. Albeit the "Encyclopædia of Materia Medica" by the late Dr. Pereira, is quite unique, yet, as Dr. Farre in his preface very properly states,

"Its copiousness, however, had become embarrassing, not indeed to those who desired to study the subject in the comprehensive spirit of the author, but to the majority of medical practitioners, pharmaceutical chemists, and medical and pharmaceutical students, who, having only a limited portion of time at their disposal, were obliged to be content with such an amount of information as they could reasonably hope to acquire, and such as might assist them in their daily occupations. Bearing this in mind I have reduced the large work to about one-third of its size, without, I trust, diminishing—may I venture to hope with some increase of—its general utility."

And further on he states:—

"Although my chief object has been to prepare a smaller work by excluding the least important parts of the 'Elements,' much new matter has at the same time been introduced into the abridgment in order that it may represent more correctly the present state of our knowledge."

No doubt the "Encyclopædia of Materia Medica and Therapeutics" will remain a lasting monument of the author's great assiduity and profound talent. Yet the names of the present Editor and his Assistants would form a sufficient guarantee for this Abridgment being carried out according to the design of the original author; but in fact the work itself is its own best expositor—indeed, we have seldom read a volume written in a more accurate and concise style than the one now before us. A brief digest of its contents and a few examples taken from each department of the book will better enable our readers to judge of its worth than any lengthened commentary on our part.

Prefatory to the general plan of the work which is very simple, the Editor gives two very important tables; the first one showing the differences in the nomenclature of the British and of the London, Edinburgh, and Dublin Pharmacopœias; the second, on the weights and measures of the British Pharmacopœia.

The Editor has arranged the materia medica according to the late Dr. Pereira's work in two groups, the Inorganic and Organic, and his two classifications of medicines are founded, one on the chemical classification of the inorganic bodies, and the other on the

botanical and zoological classifications of the plants and animals which yield the organic bodies. His second mode of classification is founded on their physiological effects. The Inorganic group is subdivided according to the chemical relation of its members; the Organic according to their external, or, as they are usually called, natural history characters.

The products of Fermentation, and these of Destructive Distillation form, each, a separate chapter, and another is devoted to those portions of the Animal Kingdom which contribute to our remedial agents, and near the end of the volume is one on the Physiological Classification of Medicines, which is succeeded by a Posological Table and a copious Index.

We subjoin at random an article from each of the two groups which will serve to illustrate the style of the work. From the Inorganic Kingdom

BISMUTH (Appendix A.)

Bi=210

Natural History.—Bismuth occurs only in the mineral kingdom. It is found in Cornwall, Saxony, Bohemia, the United States, and other localities. It is met with in the metallic state nearly pure (*native bismuth*), and in combination with sulphur and with oxygen.

Preparation.—It is chiefly obtained from native bismuth by melting the metal out of its matrix.

Properties.—It is a reddish-white metal, without taste or smell, composed of brilliant broad plates, and readily crystallisable in cubes or regular octahedrons. The sp. gr. of purified bismuth is, according to Karsten, 9.65. It is moderately hard, brittle, pulverisable, fusible at 476° F. When strongly heated in the air, it takes fire, and burns with a faint blue flame, emitting a yellow smoke (BiO₃). In close vessels it may be volatilised. Copper may be detected in bismuth by precipitating the nitric solution with ammonia; the supernatant liquor is blue if copper be present.

Bismuthum Album.

White Bismuth.

Synonyms.—Bismuthi Nitras, Lond.; Bismuthi Subnitras, Dub.

BiO₃NO₃=288.

Preparation.—Take of bismuth, in coarse powder, two ounces; nitric acid, two fluid ounces and a half; distilled water, one gallon. Dilute the nitric acid with three ounces of the water, and add the bismuth in successive portions. When effervescence has ceased, apply for ten minutes a heat approaching that of ebullition, and decant the solution from any particles of metal which may remain undissolved. Evaporate the solution till it is reduced to two fluid ounces, and pour it into half a gallon of the water. When the precipitate which forms has subsided, decant the supernatant liquid, and agitate the sediment with the remainder of the water. After two hours, again decant, and, having placed the product on a filter, dry it at a temperature of 212°.

In the first part of this process we obtain a ternitrate of bismuth by the reaction of bismuth on nitric acid. One equivalent of binoxide of nitrogen is evolved, and an equivalent of ternitrate of bismuth formed. Bi+4 O₅=BiO₃, 3xO₅+NO₂. Water decomposes the ternitrate of bismuth, and causes the precipitation of white bismuth (also called nitrate, subnitrate, or trinitrate), leaving a supernitrate in solution, 4(BiO₃ 3NO₃)+HO=3(B.O₃.NO₃.HO)+BiO₃ 9NO₃.

Official Characters.—A heavy white powder in minute crystalline scales, blackened by sulphuretted hydrogen (BiS₂), insoluble in water, but forming with nitric acid a solution which poured into water gives a white crystalline precipitate, and with sulphuric acid diluted with an equal bulk of water a solution which is blackened (rendered olive brown) by sulphate of iron (showing the presence of nitric acid).

Composition.—White bismuth, prepared as above, has the following composition:—

Eq.	Eq. Wt.	Per Cent.
1 Teroxide of Bismuth	234	81.25
1 Nitric Acid	54	18.75
White Bismuth	288	100.00

Tests.—Dissolves in nitric acid without effervescence. The solution gives no precipitate with dilute sulphuric acid (showing freedom from carbonates, as carbonates of lead and lime).

Physiological Effects.—In small doses it acts locally as an astringent, diminishing secretion. On account of the frequent relief given by it in painful affections of the stomach, it is supposed to act on the nerves of this viscus as a sedative. It has also been denominated tonic and antispasmodic. Vogt says, that when used as a cosmetic, it has produced a spasmodic trembling of the face, ending in paralysis. Large medicinal doses disorder the digestive organs, occasioning pain, vomiting, purging, &c.; and sometimes affecting the nervous system, and producing giddiness, insensibility, with cramps of the extremities. On the other hand, M. Monneret states, after several years' trial of this medicine, that it may be given in much larger doses than are usually administered, and that it is then of the greatest value in gastro-intestinal affections, especially those attended with fluxes.

Therapeutics.—It has been principally employed in those chronic affections of the stomach which are unaccompanied by any organic disease, but which apparently depend on some disordered condition of the nerves of this viscus; and hence the efficacy of the remedy is referred to its supposed action on these parts. It has been particularly used and recommended to relieve gastrodynia and cramp of the stomach, to allay sickness and vomiting, and as a remedy for pyrosis or waterbrash. In the latter disease I give it in the form of a powder, in doses of 20 grains thrice daily, in conjunction with hydrocyanic acid mixture, and the patient rarely fails to obtain marked benefit from its use. It is also used in ulcer of the stomach. Dr Theophilus Thompson recommends it in doses of five grains, combined with gum arabic and magnesia, in the diarrhoea accompanying phthisis; and he thinks that, both in efficacy and safety, it surpasses our most approved remedies for that complaint. I have used it, with advantage, in the form of ointment, applied to the septum nasi, in ulceration of this part, and as a local remedy in chronic skin diseases.

Administration.—The usual dose of this remedy is from five to twenty grains. I seldom commence with less than twenty grains, and have repeatedly exhibited thirty grains without the least inconvenience. It may be administered in the form of powder, lozenge, or pill. The ointment which I have above referred to was composed of sixty grains of white bismuth, and half an ounce of spermaceti ointment.

TROCHISCI BISMUTHI, Bismuth Lozenges.—Take of white bismuth, fourteen hundred and forty grains; carbonate of magnesia, four ounces; precipitated carbonate of lime, six ounces; refined sugar, thirty ounces; gum arabic, in powder, one ounce; distilled water, six fluid ounces; oil of cinnamon, half a fluid drachm. Add the dry ingredients to the water; mix thoroughly, and boil till the mixture is reduced to a proper consistence. Then remove it from the fire, add the oil of cinnamon, and again mix thoroughly. Divide the mass into 720 square lozenges, and dry these in a hot-air chamber with a moderate heat.

Each lozenge contains two grains of white bismuth.

Respecting the one from the Organic Kingdom, we merely give the mode of arrangement, as to give it *in extenso* would occupy too much space; but our readers will judge from the various heads under which the details are arranged how accurate and painstaking has been the labours of the Editor and his Assistants. We select the article on—

“*Opium.*—The inspissated juice of the papaver somniferum, the opium poppy (which had been previously described), obtained by incision from the unripe capsules grown in Asia Minor.

“1st. Extraction and collection.

“2nd. Official characters.

“3rd. Description and varieties, each variety being fully described.

“4th. Test of various descriptions.

“5th. Composition, giving the various constituents of opium—viz., morphia, codeia, meconic acid, &c. &c. &c., with a description and test of each.

“6. Impurities and adulterations.

“7. Physiological effects, giving in detail its various effects and large and small doses on the different organs, on the cerebro-spinal system, on the digestive, the vascular, respiratory, urinary, sexual and cutaneous systems, also its topical effects.

“8. Post-mortem appearances.

“9. Modus operandi.

“10. Therapeutics, in fevers, in inflammatory diseases, diseases of the brain and spinal cord, diseases of the chest, in maladies of the digestive organs, of the urino-genital apparatus, as an anodyne, in hæmorrhages, in mortification, in venereal diseases, in ulcers and granulating wounds, in poisoning by belladonna or stramonium, its external application.

“Administration, antidotes, pharmaceutical uses, official preparations, with a table showing the strength of each preparation of opium.”

From these examples and our general remarks, our readers will perceive that the Editor and his Assistants have no anxiety to feel as regards the performance of their task, and that they have effected a great condensation of the original work without any deterioration of its value, and at the same time have kept pace with the present progress of this department of science. The book being printed in double columns, there is consequently no loss of space.

THE HALF-YEARLY ABSTRACT OF THE MEDICAL SCIENCES: being an Analytical and Critical Digest of the principal British and Continental Medical Works published in the preceding six months. Vol. XLII. July—December, 1865. London: Churchill & Sons.

This Abstract is, as usual, a faithful retrospect of the progress of Medicine, Surgery and Midwifery, during the last six months, and the materials are derived from all available sources, British and Foreign. The last part of the volume consists of Reviews and Bibliographical notices, in which most of the published works are papers which have lately emanated from the medical press are briefly introduced, and their principal topics described.

WHO WINS? Being the Autobiography of SAMUEL BASIL CARLINGFORD, M.D. Second Edition. pp. 332. London: Simpkin & Co.

Under the guise of a work of fiction, this book is an essay in favour of the trash which goes under the name of Homœopathy. Although professing to be written by a medical man, there is abundant internal evidence that such is not the case, and that it is rather the production of some weak-minded dilettante writer, whose imagination overpowers his reason. There is, indeed, some reason to believe that it is written by some half-educated lady, so absurd is the process of reasoning adopted, and so ridiculous are the mistakes made in scientific matters. The form of a novel, in which nearly everything is of course fictitious is perhaps an appropriate vehicle for the enunciation of the shadowy absurdities of the globulistic school.

ELECTION OF EXAMINER AT THE ROYAL COLLEGE OF SURGEONS IN IRELAND—At the meeting of the College on Thursday last, Dr. John Barker was elected Examiner in the room of the late Dr. Jerome Morgan.

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 17, 1866.

THE COLLEGE OF SURGEONS OF ENGLAND.

THE College of Surgeons of England would present to any intelligent and scientific foreigner many materials for varied contemplation in the anomalies of our British institutions. The stranger would behold, not without just admiration, the magnificent fabric which rises before his eyes as he reaches Lincoln's-inn Fields, and his wonder would be still further augmented as he wends his way through the extensive and most valuable Museum of Comparative Anatomy and Pathology, which is stored in room after room in that widely renowned collection; and, if he ascends into the Library, he would find an assortment of medical and scientific books perhaps unrivalled in the world.

Although any praise bestowed on such priceless treasures on our part may probably be deemed superfluous, we cannot help remarking that the Library and the Museum of the English College of Surgeons do honour to the British nation, and more especially the Museum, which, originating in the private collection of JOHN HUNTER, has gradually swelled into colossal proportions, and now presents an epitome of organic Nature, such as has never been before exhibited to the admiration of mankind. We write with a full knowledge of the existence of a Gallery of Comparative Anatomy in the Garden of Plants near Paris, filled with the treasures deposited there by CUVIER and his illustrious disciples, and some thirty or forty years ago a comparison of the two collections would have been unfavourable to the English College; but now times are altered, the French gallery has fallen into partial neglect, while, on the other hand, its English rival has been expanding itself into larger and larger dimensions, and its value has increased in a more than corresponding degree. Under the enlightened superintendence of Professor OWEN and his successor, the lamented Professor QUEKETT, the materials have been arranged in the most masterly manner, and copious catalogues have been supplied for the explanation of all the specimens exhibited; and the present curator, Mr. FLOWER, with a zeal and an intelligence in no way inferior to those of his predecessors, is still carrying on the Herculean but delightful labour of adding fresh specimens to this great Mausoleum of Nature, and rendering its details available for the inspection of the scientific visitor and further enlightenment of the student.

But, returning to the foreigner, whom we have supposed as inquiring into the whole history and constitution of the English College of Surgeons, we should find his admiration of the building, the Museum, and the Library, mingled with wonder at the sources from which

the expenses are defrayed. We ourselves recollect the surprise and almost incredulity with which a distinguished northern Professor received our own information while walking through the College galleries, that all the funds, or nearly all, were supplied by the fees of candidates for surgical diplomas. He observed that such national institutions, as museums and libraries, were supported, in Continental countries, by the liberality of the Government, and he probably thought, though he did not say it, that the application of fees derived from diplomas to such a purpose, however honorable it might seem to all parties concerned, was a system very liable to abuse.

Now, it is true that the exclusive superintendence and support of public galleries and museums by the Government of a country is in itself likely to lead to results unfavourable to science, and to blunt the edge of individual exertion; but, on the other hand, the maintenance of such institutions by the fees obtained from candidates for Professional Degrees or Diplomas is a still greater abuse. We desire it to be distinctly understood that we make no charge of corruption against any of the authorities of the London College of Surgeons, but we maintain that in the general policy pursued by the Council, and in the system adopted in the examinations, one of the principal objects always held in view is the aggrandisement of the College funds. For this reason the College has, for a very long period, kept down its standard of qualification to the lowest possible level, in order to invite candidates within its portals; for this reason it has created a class of Fellows, from some of whom a scientific test, but from most of whom a money-test only, has been demanded; for this reason a perfectly unnecessary and separate diploma has been created in midwifery, with which the College has no concern except as a subject included in the examination for the membership; for this reason the College has devised a separate and, we believe, mischievous diploma in Dental Surgery. None of the false steps to which we have just alluded would have been taken, we verily believe, if the College could have acted with independence. It is true it has been shamed into some improvements in the mode of examination, and compelled to adopt others by the stringency of the laws of the country, and whether, from this reason or from other causes, it is an undoubted fact that the College expenses now exceed the receipts by a very considerable sum, and the results must be, either that the efficiency of the Museum or the Library will suffer in consequence, or that the standard of examination will be openly or surreptitiously lowered, or some new diploma must be devised for the purpose of raising additional funds.

If we are not misinformed, there is even now some proposition before the Council to lower the qualification for the Fellows by examination, the object, no doubt, being to attract a larger number of this class; but whether this be so or not it is certain that the present vicious system of maintaining a magnificent institution

out of students' fees ought not to be continued. The examiners, in fixing their standards of qualification and in the actual decision upon the merits of candidates, ought to have no other aim or object in view than to secure an efficient class of practitioners for the public; and we again assert that no body of examiners, however personally honourable, can possibly act in this independent manner when they know that not merely their own salaries, but the maintenance of the institution to which they belong, are dependent upon the issue.

It is well known that the College of Surgeons has received from the Government, from time to time, considerable pecuniary assistance, and we most earnestly hope that this liberality will be further extended. Such aid would do honour alike to the nation and to the College, and it would relieve the latter from the necessity of bartering its diplomas for money, and enable it to act with the dignified independence and impartiality which ought to be assumed by one of the most important of our medical Corporations.

THE ERUPTION OF CATTLE PLAGUE.

At the last meeting of the Pathological Society a very interesting discussion took place in reference to the connexion of the cattle plague and small-pox. It was started by Dr. Quain, who introduced to the society a gentleman who had inoculated himself with the morbid secretions of a beast which had died of the rinderpest. It presented all the characters of cow-pox, and has been seen by Mr. Coely and others. Dr. Quain drew attention to the features of the analogy of rinderpest and small-pox, in details which accorded with the statements made by Dr. Murchison in the *Lancet* of December 31st, commenting especially, however, upon the fact that the eruption in rinderpest had been overlooked and often unrecognised till the skin reached and was removed from the tan-pit, when the spotting of the hide became visible. Dr. Sanderson took exception to the characters of the eruption as diagnostic of small-pox; indeed he expressed himself strongly to the effect that it was never, as affirmed, vesicular; he thought that it consisted simply of detachment of the epithelium and softening of the structures beneath, this condition of things being also observed in the mucous surfaces, especially about the mouth and lips. The papillæ of the cheek being devoid of epithelium, flat greyish patches or papillæ forming over the surface. Professor Gamgee agreed with Dr. Sanderson, that in his experience the eruption could not be regarded as that of small-pox; he had seen depressed papillæ, which even became confluent, but they were analogous to the changes produced in the whole tract of the intestinal canal, which were constant, whilst these of the surface varied much. He agreed in the main with Dr. Sanderson, in the detachment and shedding of the epithelium at the earliest stages. In addition he called special attention to the implication of the little glands of the mucous membrane, whose cells were rapidly thrown off, reproduced, and retained, choking up the follicles. The eruption in the skin partook of the same character and was not vesicular. He cautioned observers against any hasty conclusions in reference to the latter, for many cases of severe eruption of an ecthymatous nature were on record produced by the contact of irri-

tating animal secretions. As it was mentioned at one part of the discussion that the character of the skin of the ox might account for modifications in the aspect of small-pox eruption, Dr. Sanderson observed that the plate which he handed round from Professor Simmond's work, showed clearly that in the sheep the eruption of small-pox is distinctly vesicular. Dr. Murchison admitted that there was a want of distinctness about the characters of the eruption, but observed further that modifications often resulted in man and animals in regard to the eruption of small-pox as witnessed in India, the small pox poison produced in children sometimes variola and sometimes cow-pox. He did not defend the identity of rinderpest and small-pox upon the ground of similarity in the appearances of the eruption, but the symptoms and aspect of the disease in its general details, and the post-mortem appearances were particularly similar; it was rare to get a post-mortem of small-pox now, but from special inquiry and observation on this point he had been struck with the remarkable identity of the lesions in the two cases. Experiments had already been commenced to test the truth of the supposition, and a few weeks would probably decide the matter one way or the other. Now this discussion is a very important one, indeed we conceive up to the present time no objection has been taken to the close relationship which exists between the general aspect and features, such as premonition, incubation, contagiousness, symptoms, &c. of the two diseases. The difficulty and objection to the reception of the doctrine of identity are found in the eruption itself. What are the probabilities of the case? The French have carried on some very remarkable experiments on this point, which would lead us to suppose that there are many degrees of expression of variola, especially in reference to the aspect of the eruption, and it will be remembered that a discussion took place not long since at the French Academy on this point. Variola, and cow-pox, and vaccinia are now generally admitted to be related. MM. Bouley, Depaul, Mathieu, and Dr. Auzias Turenne, and others, have shown that one variety of grease in the horse, is capable of giving rise to cow-pox in the cow; that a vaccine pustule can be produced by inoculation with matter taken from a vesicle of what has been called aphthous stomatitis in a horse, and Dr. Tilbury Fox, in the *British Medical Journal*, 1864, has given us an account of an epidemic of contagious impetigo he witnessed, apparently a modified form of vaccinal or variolous disease, and which assumes a decided importance at the present time, inasmuch as the diagnostic characters between it and the contagious furuncaloid referred to by Mr. Gamgee were given. In India peculiar modified results also are observed; cases of bastard vaccinia too are not uncommon. As we have seen a good many of these different instances of eruption, we may be allowed to say that we think there is sufficient character to warrant us in diagnosing at once between the ecthymatous batch produced by the contact of irritant secretions, and it is the peculiar tendency to early umbilication in all cases of a varioloid nature, due to the peculiarity of the contents of the vesicle. There is clearly then a wide range in the appearances of the variolous eruption, and it is quite consonant, we think, with clinical and experimental observation, that the characters of the eruption of cattle may, upon further inquiry, turn out to be those of a modified form of variola. We wish to see the matter placed on a fair footing, to encourage investigators to undertake cheerfully the hard task before them,

and to deter those who are pledged as it were to contrary opinions, from using unfairly the influence of accepted theories. It remains then, first of all, by experiment to show that animals inoculated with cow-pox or vaccine matter, are proof against the poison of small-pox, that the inoculation of subjects by matter taken from man, affected from the cow suffering from rinderpest, produces the same disease, and that the modified aspect of the eruption in rinderpest has analogies elsewhere.

[FROM OUR OWN CORRESPONDENT.]

London, January 13th, 1866.

THE news of another baronetcy having been conferred on a member of our profession has been received with as much satisfaction in this metropolis as in Edinburgh, where Sir James Y. Simpson first made, and has since so honourably maintained, his position as one of the most distinguished physicians of the day. All your London medical contemporaries are loud in their praises of the last-made Baronet, who receives the distinction as a recognition from her Majesty of the Professor's "many services to the science of medicine, especially in the discovery and the application of chloroform, by which pain in surgical operations has been alleviated and human life, in consequence, rendered more secure against disease." It is stated that a baronetcy has never before been conferred on any member of the profession practising in Scotland.

The British Medical Journal probably exhibits the least satisfaction of any of your contemporaries at the elevation of Sir James, and draws comparisons, which, as Mrs. Malaprops observes, are particularly odorous on the present occasion. The editor does not appear to know what has taken place in the medical world, or he would not have expressed such innocent child-like wonder at the honour not having been conferred on that Nestor of British Surgery, as *The Times* designates William Lawrence, and that other great man, James Syme. It is stated that the former gentleman has refused the honour, and that nothing but a peerage will now satisfy the latter. The doctor admits his ignorance as to who the advisers of the Crown are in matters of this kind, and expresses a hope that it will come to their knowledge that the profession does not consider its claims fully satisfied by the present distribution of honourable distinctions. Now, I thought it was very well known through whom these recommendations were made, and if I am not very much mistaken, I think the *British Medical*, in common with all the Medical Journals, has expressed intense satisfaction at the admirable merit always displayed by Sir James Clark in the selection of these recipients of his sovereign's favour.

Our Medical Societies set an example which might be followed with advantage elsewhere; here are congregated all the most distinguished men of the day to countenance and support all those who bring their papers for discussion, utterly regardless of the weather and all those social pleasures so prevalent at this time of the year. Let any country surgeon desirous of seeing at once all the great "pills" of the day, he has only to repair to the Royal Medical and Chirurgical Pathological and London Medical Societies, and his wish will be gratified. On Monday night Dr. Litbury Fox will read a paper at the London Medical Society on leprosy, with notes taken during his recent travels in the east. At the Harveian Society Dr. Drysdall will read a paper on the medical aspects of prostitution.

Our Examining Boards are also busy. At the College of Surgeons 65 gentlemen are now going through their Primary or Anatomical and Physiological Examination, and on Saturday next will commence their Pass or Surgical and Pathological Examination for diploma of membership. At the College of Physicians the examinations will commence on the 6th proximo, extending to the 13th, for the second part. At the Apothecaries' Hall examinations will also be held on the 26th and 27th inst.

I see that Sir William Fergusson's baronetcy is at last published in the *London Gazette* of Friday; long may he live to enjoy the honour and old lustre to the Council of the Royal College of Surgeons.

The Medical Directories of the United Kingdom has made its appearance, and I am sorry to say anything in disparagement of this useful publication, but the complaints made last year are again repeated, at the bad taste, to use the mildest term, of the editors in exposing to the general public the names of *unregistered* but legally qualified practitioners. This is done by prefixing a (†) to distinguish those who had not so registered under the Medical Act. Let us fancy a cantankerous, ill-conditioned fellow anxious to shirk the payment of his doctor's bill; he turns to the Directory and finds, let us say, for example, Dr. Haughton, of Trinity College, Dublin, A.R.S. (perhaps this gentleman is not in practice, but his name, with the dagger affixed, is the first which catches my eye). "Oh," says the ungrateful patient, "I won't pay, because he is not registered." It is true the ceremony of registration can be soon accomplished, and the cross-grained varlet defeated, but look at the trouble and inconvenience given to those stilettoed practitioners by this most objectionable and unwarranted exposure. Another complaint is the assumption of titles by certain individuals having no claim whatever to them, and who are thus allowed to parade them before the public. Others appear as authors on taking popular subjects. I have a bad case now before me, where a man became, "in the year of grace" celebrated by the Horton and Meredith affair, a "M.R.V.S." This worthy has made a return, repeated year after year, of being the author of a work, "On the non restraint system in the Cure and Treatment of those Mentally afflicted, and as being surgeon to an institution which never existed except in the fertile imaginations of this ingenious individual. There are too many of this sort of men in our profession, of whom Miss Edwards says, in her recent novel of "Half a Million of Money," belong to that class whom Nature seems to have run up by contract, whose understanding the very smallest weight of knowledge would have at any moment broken down, while his little ornaments of manner were all in the flimsiest modern taste, who played croquet well and billiards badly, and was saturated through with smoke like a finnan haddock. There is an old saying and a very true one, that "the writer of an anonymous letter is a knave, and he who believes it a fool." Regardless of this proverb, I will send a few illustrations of the correctness of my statements to the publishers of the Directory, and if they will not take me for the former I certainly will not accuse them of the latter.

On the night of the 4th inst. Dr. F. Tietjen, first assistant of the Berlin Observatory, discovered a new planet of very pale colour, belonging to the well-known group between Mars and Jupiter.

HOSPITALS AND THEIR CONSTRUCTION.

AN able article in the "British and Foreign Medico-Chirurgical Review" attributes the increase of and more extended usefulness of Hospitals to the spread of Christianity, inculcating as it does that desire for doing good to our kind, which constitutes the chief feature of the Hospital system. In the earlier ages of Christianity the religious element had much more to do with Hospitals than has been the case at least in Protestant countries in later times. Now, however, various denominations have shown a tendency again to carry out a system of nursing according to religious sects. It is not, however, the subject of the original foundation and character of Hospitals that most concerns our profession, but the rendering these institutions as perfectly adapted to the ends required. In these matters it must be generally admitted that Hospitals have not, either in their construction or management, kept pace with advancing civilization. Their primary end and aim, as the writer observes, that of curing their patients as speedily and completely as possible, has not been kept prominently enough in view. Efforts have been expended rather in favour of multiplying patients within their wards, than in making Hospitals instruments of treatment; facility of access has been more studied than facilities of cure; and the administration of medicines and brilliant or ingenious operations have received much more attention than the provision of good nursing, of pure air, and free ventilation. Unlike the *Æsculapian* temples of ancient Greece and Rome, and the earliest Christian Hospitals, our predecessors have studied convenience of locality more than in all cases salubrity of site. Now, however, attention is again being paid to locality more than has been of late in many instances the case. At the recent discussions of the Surgical Society of Paris many speakers agreed that the larger general hospitals should be placed in the country and only the small infirmaries for urgent cases and accidents and for clinical instruction be constructed in towns. M. LEON LE FORT and M. LARREY advocated the adoption of this system which was understood to have been accepted as the opinion of the society generally.

Miss NIGHTINGALE, Sir RANALD MARTIN (the writer of articles on Hospitals in the *Builder*), and POZZI, all advocate a like principle. The latter author, indeed, viewed the Hospital as injurious to the inhabitants of towns when placed in their midst. Opposed to the views of the French school of the present day, and to those of the authorities in England, whom we have quoted above, are the opinions of Messrs. BRISTOWE and HOLMES, who held the inquiry for the Privy Council, published in 1864. The reviewer in the journal under our consideration observes:—"Having now before us the principal reasons urged *pro.* and *con.* for the erection of hospitals in the country, a few words by way of comment may be here introduced. If it be allowed that 'Subsidiary Hospitals' in the

country are desirable, the whole question becomes one of the proportionate development those institutions should assume relative to the town establishments. In other words, it becomes a question of selection of cases admitting removal, of the relative number of such cases, and of the available means of transit. Dr. BRISTOWE and Mr. HOLMES would, for their part, in the case of London, to which their opinions refer, retain the present large Hospitals and erect auxiliary institutions in the country, whilst the members of the Surgical Society of Paris, Sir RANALD MARTIN and others, on the contrary, would adopt rural sites for the principal Hospitals, and construct smaller buildings as supplementary to them within the town precincts for casual and severe cases of disease and for clinical instruction. By the one scheme Town Hospitals would constitute the principal places of treatment; by the other, the Country Hospitals. The admission by the Commission that improvement in the present system of Town Hospitals is needed, renders useless any lengthened argument on the point.

The mortality of three great French Hospitals, Val-de-Grace, Gr^os Caillon, and Vincennes, shows in military cases—and as such in uniform kinds of cases—the advantage of a rural site over a town one, as well as in the benefit derivable from hygienic improvements, &c.

The writer in the "British and Foreign," after a careful review of the whole question, concludes that the open country offers the best site for a sick hospital.

HUSSON, UYTENDOEVEN, and Miss NIGHTINGALE, have shown how much neglected this most important consideration has been in past times, not only on the Continent, but also in Britain. Miss NIGHTINGALE advocates the pavillion system of architecture, pointing out that other arrangements—such as that of the Hospital surrounding a quadrangular court—"stagnate the air even before it reaches the wards," &c. The air outside the hospitals cannot be maintained in a state sufficiently pure to be used for internal ventilation unless there be entire freedom of movement. Anything which interferes with this is injurious. The new Herbert Hospital, near Woolwich, the new Leeds Hospital, the Bucks and North Staffordsire, and other County Infirmaries, as well as the new St. Thomas's Hospital, London, have all adopted the pavillion system. In Dublin, the Cork-street Fever Hospital new building is an example of this style, the advantages of which we may shortly state are—thorough ventilation by opposite windows, complete exposure of every part of the building to the influence of light and sun, and this, with a sufficient area around, free from other buildings, so as to insure a space of at least twice their own height; if there be more than one pavillion confers an immense benefit on the patients. We have seen additions made to hospitals, originally constructed on this plan, which quite interfere with the original design of the building. St. John's Hospital, Brussels, constructed on the pavillion system, has the injurious addition of corridor communication on the ground and first floor, which, as UYTTER-

HOEVEN states, is so built against the pavilions as to form a sort of "common conduit, where the vitiated air from the several wards may intermingle and suffer detention in its passage externally."

The Lariboisière Hospital has not met the approval of the Paris faculty, as, though intended to have been on the pavilion system, its several sections have been placed too close to one another, and in this way the free exposure to sun and air has been interfered with. On the other hand, the Vincennes Military and the Malta New Hospital are examples of well-constructed pavilion Hospitals, and have the approval of the Paris physicians.

Our space only permits us to say that we must agree with the review in the "British and Foreign Quarterly," which regards the result of the inquiry into the very important Hospital question held by Messrs. BRISTOWE and HOLMES, as unsatisfactory, inasmuch as they have not once and for all expressed a decided opinion as to the best model on which to construct an hospital, but have allowed matters of expediency as to expense, *status quo, &c.*, to weigh as more important in their eyes than the answer to the question, which mode of construction is the best? For our part, we have no hesitation in commending the pavilion as the most desirable system on which to construct an Hospital; and we speak after observation, and after having duly considered the practical working of this and several other modes of Hospital construction. In conclusion, we think it but right to state that the pavilion system is not new in Dublin, as it is seen in the Cork-street Fever Hospital, in the House of Industry, now the North Dublin Union Hospital, &c.

MEDICAL EDUCATION IN THE ENGLISH UNIVERSITIES.

DR. HUMPHRY, in a letter to the *Lancet*, says that the question of University extension, which has been so largely discussed with regard to candidates for Holy orders, is worthy of consideration with regard to the influence it might be expected to have upon Medical students, especially as degrees in medicine are being more and more sought, and the aspirants are eager to obtain the degrees of the old Universities, which, for various reasons, have ever been in the highest degree esteemed. Having carefully considered the various proposals which are being canvassed, he proceeds to say that he does not anticipate much from them, for the following reasons:—

1st. The Universities and the several Colleges (more particularly Cambridge) are freely open to all students of all classes, and provided the student can afford the time and expense, any one can enter. Then, having passed the examinations, he may proceed to the degrees. He considers that the disadvantages of being a member of a College during residence in Cambridge are greatly outweighed by the social and other advantages of such membership. The expenses of the student at the Uni-

versity are little, if at all, greater than those of the medical student in London. He believes that the expenditure in Cambridge and London are about alike (£120 a year). Some University men have ample means, and are lavish in their expenditure; some who have not the same means are induced by the example of others to exceed the proper limits. These are usually regarded as the types of University students, being the two classes most known and written about. But the greater number are economical, and pass through their University career at a moderate cost. After all, the real source of expense and the real obstacle to the extension of University education must still remain, since it is essential to the advantages of a University education—namely, the additional time required.

A "University Education" means, for one thing, an "extended education," and the parent who makes up his mind to the cost incurred in giving his son this extended education will like to combine with it the advantages of the University course; those attached to his being a member of a College as well as others. Finally, if a parent wishes his son to receive the benefit of a University education he may calculate on having to maintain him as a student for about two years longer than he otherwise would. The cost of that need not exceed £120 a-year, and perhaps the extra expense incurred by a University education may be calculated at £100. This, of course, does not take into account the numerous Scholarships, varying from £40 to £80 a-year, which are bestowed on those who are most proficient in their school work, or who have acquired a certain knowledge of Natural Science. Nor does it take into account the Fellowships which are given to those who highly distinguish themselves at the close of their University career. Whether the investment will prove a good one must depend upon the extent to which the student avails himself of the opportunities offered.

A NEW CLOSE STOOL.

SANITARY science, a most necessary and admirable thing in itself, is the fashionable foible of the day, and the manner in which some otherwise estimable men carry it out, is a striking exemplification of the statement, "that a little knowledge is a dangerous thing." In a letter from India, we read lately:—"I had a terrible job in my jail hospital, when I took charge—men overcrowded, and dying of typhoid—the floor saturated with urine, and worse. I have now, however, got cleanliness and a better hospital, and am reducing the numbers in the jail, and I trust, at least, to be better than the first six months of the year, in which about 150 out of 1,000 died—70 in one month; yet, strange to say, little was done to check the grand evil—the excessive mortality being attributed to a jheel, or swamp, twenty miles off! by the surgeon then in attendance, who has the reputation of being a very clever fellow, certainly not undeservedly." And just the other day we heard that an epidemic of typhoid in an open, well-aired village, not twenty miles from Edinburgh, was attributed to what, think you? *To the want of drains!* Shades of Murchison and William Budd, are your labours in the cause of science and humanity so little known within twenty miles of your *alma mater?* The smell around the houses was stated to be

something horrible; and no wonder, for heaps of pigs and human ordure are accumulated at the back of these houses, and mingled with these heaps are the stools of the typhoid patients, *not disinfectd*. No wonder the disease spreads, ay, and will spread. It is not drains, but common sense that is wanting there, and a few handfuls of chloride of lime and a scavenger, are all that are wanted to keep this village free of such fever, both now and for ever. Moreover, we know well that drains, and water-closets, are only too frequently sources of danger and death in the houses of the rich even, and still more in the houses of the poor; and that, where it can be carried out, there is no plan at all comparable in safety and economy with removing the excreta *en masse* from the neighbourhood of the dwelling, to apply them to the soil of which they are the natural food, and which they enable, in its turn, to bring forth those various products, which are the food of man and animals. Besides, the actual danger involved in the ordinary mode of getting rid of these excreta, particularly in towns, it is attended with a wasteful extravagance, the character of which may be judged from the following quotation from a paper upon "The employment of water in the removal of excreta from dwelling-houses," recently read by Mr. Alexander Ramsay, the manager of the Edinburgh Water Company, before the Royal Scottish Society of Arts:—

"In the report by a committee of the House of Commons on the Sewage of the Metropolis, in Appendix No. 14, there are a series of tables by J. L. W. Thudicum, M.D., in one of which (No. 16) he states the value of the excreta of the population of London to be £1,165,495 per annum. Of course, this is on the assumption that the whole were collected, which, in any case, is impossible. It may be taken, however, as a foundation for a calculation in the case of Edinburgh and Leith. Taking the population of London at 3,000,000, and roughly estimating Edinburgh and Leith at 200,000, being one to fifteen of London, the value of the excreta, estimated at the same rate as in London, will amount to £77,699 per annum. I do not for a moment imagine that it would be possible, under any law that could be devised for the collection of this wasted matter, to realise so large a sum. I am clear, however, that if the use of water-closets were abolished, and some such arrangement as that I have suggested substituted for it, a clear income of not less than £25,000, but probably upwards of £30,000 per annum might be derived from it. This, however, represents only a portion of the loss by the present system. A sum of £10,000 a year as the cost of making and maintaining house and other drains may be safely added, bringing up the annual loss to from £35,000 to £40,000 a year. To this large sum there yet falls to be added the water so uselessly wasted. At this moment the consumption of water per day is somewhat upwards of what would furnish thirty gallons per head to a population of 200,000 persons. If water-closets were discontinued, and supposing that only fifteen gallons per head per day of water were set free and applied to the purposes of trade and manufacture, the income which might be derived by its sale, might probably bring up the sum lost by the present system to something between £40,000 and £50,000 a year, and all this without taking any account of the increased quantity of food which would be derived from the application of that excreta to the soil."

To remedy this waste, and to obviate these dangers, Mr. Ramsay recommends the introduction of a new form of close-stool, which he thus introduced to the notice of the Society:

"If it were not from the fear of startling the Society, I would go so far as to say that water-closets are at this moment productive of far more evil than good. Passing over other evils connected with them to which I have already adverted, I contend that the act of raising the handle of a water-closet unavoidably introduces into the house a quantity of foul-air from the soil-pipes or drain, greater or smaller in quantity, and more or less noxious in its effects, according to the size and condition of the soil-pipes, drain and apparatus with which the water-closet is connected. You will please to observe that, while this is a great and unquestion-

able evil, it is an evil superadded to the merely ordinary and proper purposes of a water-closet, and inseparable from it. From this evil, at least, the model before you is free. To give it a distinctive name, I will call it a Chamber-closet. The closet consists of two vessels, the upper one of which is covered by a valve, intended to be constantly closed, except when the closet is in use. This vessel is a sort of representative of the basin of a water-closet. Its lower end is also closed by a valve, which, when withdrawn, frees itself from, and deposits the soil in the vessel under it. When that vessel is full, it is detached by moving it a couple of inches round, so as to undo the bayonet screw, by which it is coupled to the lower part of the basin. When the full vessel is to be removed, it is covered with a lid which is secured in its place by the bayonet screw. An empty vessel is then put in, and soon continuously. On the shoulder of these vessels there is a small tube terminating in a coupling screw, for the purpose of attaching a pipe to carry the gases generated in the vessel into the open air. I should add that the valves are nearly air-tight, and may be made entirely so, and are opened and closed only when the closet is being used. The basin may be rinsed with water when it is thought necessary; but my view is, that as far as possible, the contents of the lower vessel should not be subject to dilution. The vessel itself being externally clean, its removal may be effected with less offence to sight or smell than is occasioned by the carrying of a house-maid's pail from one apartment to another."

We commend this chamber-closet to the attention of our friends, both in town and country, assured that the time is fast approaching when the absurdity of spending enormous sums in carrying into the sea what ought to be a source of wealth to the community, will be regarded as one of the most extraordinary fallacies of the nineteenth century, apart altogether from the danger inseparable from the system, and from the pollution of the rivers, which is its necessary consequence, unless we restrict large towns entirely to the seaboard of a country, which is an impossibility.

In the conversation which followed the reading of this paper, all the speakers spoke favourably of this plan, and one of them,

"Mr. John Reid, C.E., approved of Mr. Ramsay's plan, and said that he had been in the Netherlands for upwards of two years, where matters were managed on a plan similar to that proposed. Every night carts, or rather close vessels mounted on wheels, passed through the streets, received the excreta, and thence carted the substance direct to the fields. The population of the country probably was the most dense in Europe, and with naturally a poor soil—chiefly sand—yet there was scarcely a yard of land but what was luxuriant with vegetation, and this was, he thought, due to the care which the municipal authorities took for the conservation of the excreta of the different towns."

The Chinese are also well known to make large use of the fertilizing properties of human ordure. We should like to know what is their mode of collecting and distributing it. For we may rest assured that the deficiency of manure resulting from the ravages of rinderpest, as well as the too long delayed legislation on the pollution of rivers, will make this one of the most important sanitary questions of the commencing quinquennium.

MEDICAL ANNOTATIONS.

THE PATHOLOGY OF THE CATTLE PLAGUE.

DR. MURCHISON has lately expressed an opinion that the cattle plague resembles small-pox in many of its characters, and he supports this view with great ingenuity and learning. He admits, however, that great differences appear to exist between the disease known as human small-pox and the epidemic of the cattle; but still he conceives that the two diseases are essentially the same, the character of the erupt on being modified by the nature of the skin of the animal. But the pathological nature of the affection

is comparatively unimportant in a practical point of view, if any preventive measure could be devised to protect the beasts from the epidemic, and Dr. Murchison goes so far as to assert that vaccination of the cattle does really offer this protection. If such should turn out to be the case we need not point out the immense value of such a suggestion as that made by Dr. Murchison, and we only hope that his statements will be verified by experience. In the meantime, we understand that vaccination of cattle is being performed throughout England and Wales, and we shall therefore be able to judge of the success of the measure at no distant period.

“DR.” HUNTER AND THE *Pall-Mall Gazette*.

The action brought by “Dr.” Hunter against the *Pall-Mall Gazette* for an alleged libel will, we believe, be tried in the present term, and the case has already been the subject of an application to the judges sitting *in banco*, “Dr.” Hunter calling upon the defendants to furnish particulars of their plea of justification which they have placed upon the record. The application, however, was unsuccessful, the Chief Justice remarking that the plea of justification did not require any particulars to be set forth before the trial. The arguments were necessarily technical, but still the Lord Chief Justice (Cockburn) gave a pretty strong intimation that Hunter had laid himself open to criticism on the part of the press. It is a somewhat curious fact that Mr. Hume Williams, who appeared as counsel on behalf of Hunter, is on the staff of the *Lancet*, and is generally supposed to be the legal adviser to that journal.

THE QUEKETT CLUB.

WE noticed in a number of a previous date, the establishment of a Microscopical Society under the title of “The Quekett Microscopical Club,” started by Mr. W. GIBSON with a view to giving microscopists ampler opportunities of advancing in their pursuit than they already possessed. Since our notice, the Quekett Club has created a sensation in the scientific world. In its establishment we see an example of what well directed energy will do, even in the hands of an as yet unknown amateur. The committee have shown a delicate appreciation of the labours of Professor Quekett, in the selection of the title, and we trust this infant Society may be a long standing memorial to his memory. Every meeting brings large additions to its roll of members; surely the best guarantee of its usefulness. At the last ordinary meeting held at their commodious rooms, 32, Sackville Street, Piccadilly, P. LE NEVE FOSTER, Esq., one of the Vice-Presidents, in the chair, a paper was read on the determination of vegetable fibres (used in the manufactures) by the aid of the microscope. This is a most important subject, and if the Quekett Club succeed in working it out, and giving us the distinctive microscopical features possessed by certain fibres, they will not only have given the microscopist a fresh subject to work, but have rendered the public a benefit; for when the manufacturer knows there are means whereby his frauds can be detected, he will be less likely to substitute a poor substance for the genuine article. A committee has been appointed from amongst the members to report upon the subject, we hope to give the result of their investigation in those pages, and shall anxiously await it. Mr. BECK has read several papers on “Insect Anatomy,” illustrating the lecture by some beautiful dia-

grams. He advocated the study of the various parts of insect structure as they appeared on the insect itself, and not to so great an extent when having gone through various processes of pickling the object appeared as a mutilated image of its former self, often hardly recognisable. This Mr. BECK most clearly exemplified by first showing the spiracle of a common house fly as it appeared while a permanent object, and then the same object *in situ*. For beauty the former was not to be compared to the latter, but laying aside the appearance of the object as a pretty piece of mechanism, a most important part had been destroyed in the preparation of the insect, many of the fine hairs which keep the dust from the spiracle, being absent, so that very little idea could be obtained of the manner of its working. Members of the Quekett Club most assuredly ought not to lack material for their studies as each meeting gives them occupation for the ensuing month and sends them away with a fresh impetus for their fascinating pursuit; the younger members most likely with the intention of still further elucidating the subject they heard discussed; a purpose soon perhaps to be cast to the ground with the first failure, and requiring another meeting to have set up again and strengthened.

POOR-LAW INTELLIGENCE.

PAYMENT OF MEDICAL OFFICERS FROM THE CONSOLIDATED FUND.

DEPUTATION TO THE CHIEF SECRETARY.

ON the 9th inst. a numerous and most influential deputation from the various Poor Law Unions throughout the country waited upon the Right Hon. Chichester Fortescue, Chief Secretary for Ireland, at the Chief Secretary's office, Dublin Castle, for the purpose of urging upon the Government the claims of the payers of poor's rate to have half the salaries of the Medical Officers, and the whole of the educational expenses of the Poor Law Unions of Ireland defrayed out of the Consolidated Fund.

The following gentlemen composed the deputation:— Sir Robert Gore Booth, Bart., M.P.; Colonel Taylor, M.P.; Sir Robert Shaw, Bart.; Sir James Stronge, Bart., M.P.; Sir M. Crofton, Hon. Robert Handcock, Colonel Knox Gore, Captain King, E. Wingfield Verner, Esq., M.P.; Hans H. Woods, Esq., D.L.; Jonathan Pim, Esq., M.P.; Colonel Cooper, M.P.; Dr. Purdon, N. P. Leader, Esq., M.P.; Edward Sanderson, Esq., M.P.; Captain Lindsay, D.L.; Charles Cobb, Esq., D.L.; George Skippon, Esq., D.L.; J. T. Reilly, Esq., D.L., J.P.; Richard Kavanagh, Esq., D.L.; H. J. MacFarlane, Esq., J.P.; John Byrne, Esq., J.P.; John E. Vernon, Esq., J.P.; J. P. Kennedy, Esq., J.P.; George Austin, Esq., J.P. William James Armstrong, Esq., J.P.; Richard J. Smith, Esq., J.P.; James Roe, Esq.; John Finlay, Esq.; J. B. Burne, Esq.; A. Ormsby, Esq.; Richard Challoner, Esq.; Captain O'Callaghan, William Archdall, Esq.; Dr. Taylor, — L'Estrange, Esq.; Alderman Bonsall, J. L. Christie, Esq.; William Kemmis, Esq.; Captain Patterson, William Pidgeon, Esq.; O. J. Caraher, Esq.; and George Hepburn, Esq.

Colonel TAYLOR introduced the deputation.

Mr. BYRNE said that the deputation waited upon the Chief Secretary in consequence of a resolution passed at a meeting of the Balrothery Union on the 23rd of August last.

It is divided into two parts, one claiming half of the salaries of the medical officers, and the other the whole of the educational expenses connected with Poor-law unions in Ireland. The proceedings which led to the introduction of the Medical Charities Act in 1852, I need hardly go back upon. At the same time, in 1852, when it did

come into operation, this country had scarcely emerged from the awful crisis which it had passed through. The extent of the relief which that Act of Parliament has given to the country has materially benefited it, but it has done so at a very large and increasing expense upon the Poor-law establishment of Ireland. That expense has been growing from 1854, when it was £89,707, to last year, when it was £114,935, each succeeding year producing an increase in the taxation. In fact, at present, sir, the cost of the medical charities in Ireland is about one-sixth of the whole cost under the Poor-law Relief Act (hear, hear).

This Act also has been introduced since the Poor-law, as one of seven Acts of Parliament which have been passed in reference to this country, and the chargeability of the whole of which has been attached to the Poor-law system. Those Acts of Parliament are—The Nuisances' Removal Act, the Diseases Prevention Act, the Medical Charities Act, the Emigration Expenses of the Poor Act, the Registration of Births, Deaths, and Marriages Act, the Expenses for the Burial of the Poor Act, the Parliamentary Franchise Act, and the Vaccination Act. This deputation grounds its coming here to-day principally on the report of the committee of the House of Commons, which was appointed last year, on the subject of taxation, and which report states this important fact, that from the year 1851 to 1861 the taxation of England necessarily increased 20 per cent., whilst that of Ireland was increased 53 per cent.; and as gentlemen who represent the various unions in Ireland, and I may say the most important interests in Ireland, we feel that the time has arrived when some of those extraneous branches ought to be lopped off that serious chargeability of this country and that we should narrow its limits as much as possible to the relief which was originally intended to be given (hear, hear). The recommendation of the committee of the House of Commons last year was that the half of the salaries of the medical officers, and the whole of the educational expenses, should be borne by the Consolidated Fund, as was the case in England. But that committee went a little further, and said—"It is evident that if the Poor-law of 1846 was what the Poor Law of 1864 is, the Government would not have hesitated in making the grants simultaneously." This question was introduced into Parliament by the hon. member for Meath, and was defeated by a very small majority. I do not intimate this with a view to the suggestion of any independent action outside the Government; and, if you, sir, go before Parliament with the full confidence that you have, as, indeed, you have, the unanimous expression of opinion in Ireland upon this important question, and that you have the reasoning of the English members to support you, I have no doubt, sir, that in the next session of Parliament this measure of justice to this country will be obtained (hear, hear).

Colonel KNOX GORE then addressed the Chief Secretary.

Sir JAMES STRONG, M.P., also spoke in support of the object of the deputation.

Mr. H. J. MACFARLANE also spoke in behalf of the objects of the deputation. He wished to state while the total Poor law expenditure of 1863 was about £605,000, the medical charities were £109,000, or rather more than one-sixth.

Mr. LEADER also contended that it was a great hardship to have this tax levied. There was another serious tax, namely, that for lunatic asylums, which in his own county amounted to one-tenth of the grand jury cess, paid by the working farmers, and not by the proprietary.

Mr. SKIPTON, who stated that he represented Londonderry Union, stated that in that place the medical charities expenses amounted to a very large percentage of the poor-rates.

Mr. FORTESCUE—Gentlemen, I am sure you will not think that I wish any disrespect to this very important and influential deputation, if what I say is short, and if it

is not very positive or definite. Under the circumstances, you will not be surprised that that is the case. It is quite plain that the real ground upon which these changes are urged—and this ground does strike the mind of everybody who has looked at the matter—is a very simple one: that those local charges are borne by the Treasury in England, and not borne by the Treasury in Ireland. Of course, it would require a good deal to upset that very simple ground, upon which this application to the Government and Parliament is, and has long been supported. At the same time, I must candidly say that the matter is not so simple a one as it appears at first sight to be, as is very well known to anybody who has really examined the whole subject, because, of course, these two particular items cannot be taken alone, but a balance is to be struck between the circumstances of the two countries in respect to local taxation in all its branches, and the real assistance which that local taxation receives from Imperial funds; and if the whole case be viewed in that way, I must say that it is not so simple a one as many gentlemen are apt to suppose, and that those who have hitherto, on the part of the Government and the Treasury, declined to comply with this request, are by no means so destitute of argument in the matter as is sometimes imagined to be the case. But, for myself, I will not carry official reserve so far as to say that I have changed my mind since I myself voted in favour of a recommendation of this particular change in the committee of which I was a member in 1858. It so happened that that committee, as is well known to most of the gentlemen present, considered this whole subject, and made several recommendations, some of which, and very important ones, relating to criminal prosecutions and the expenses of Crown prisoners in county gaols, have been carried into effect. With respect to these recommendations the committee were unanimous. With respect to those two which form the subject of this deputation—namely, the charge for the half-cost of medical officers and the charge for workhouse schoolmasters, the committee were not unanimous, indeed, but it so happened that the view I took at the time led me to vote in favour of that resolution (hear, hear), and my name appears in the Blue-book as so voting. Well, I think it would be absurd for me personally to carry official reserve and pedantry so far as to say that I am not still personally of the same mind; but of course it becomes a question for the Irish Government whether they will be prepared to urge this change upon the Treasury. It is really a Treasury matter. *It lies in the last resort entirely with the Treasury, and the only part that the Irish Government could take in it would be by way of advice and recommendation. I cannot, therefore, say more than this, that my noble friend the Lord Lieutenant and myself are prepared to consider whether it may not be our duty to give that advice and to make that recommendation (hear, hear). I will not say less than that, but I cannot say more than that; and, if you will allow me, I must ask your leave to leave the matter at present in that state, at the same time assuring you that I will take good care that the Cabinet and the Chancellor of the Exchequer shall thoroughly understand the nature of the remarkable deputation that I have received to-day, and how I believe that they are thoroughly representative of the feelings of Ireland and of the wishes of every poor-law union in the country. I shall only be fulfilling my duty in doing that, and I shall take care that that shall be effectually done. The deputation will not understand me to commit the Irish Government, and still less, of course, the Cabinet and the Treasury; but I am authorized, after consultation with my noble friend the Lord Lieutenant, to say as much as I have said.*

The deputation then withdrew.

HEALTH OF GLASGOW.—At a meeting of the Sanitary Committee held last week, Dr. AEGLE reported that during the last fortnight 228 cases of typhus fever had been reported, being the same as the number reported for the previous fortnight, and six cases of small-pox, against five during the previous two weeks.

RETROSPECT OF THE JOURNALS.

THE *Lancet*, *Medical Times and Gazette*, and the *British Medical Journal*, are full of the rinderpest and its scientific bearings. Notwithstanding that the plague has been some months among us, yet the disease in England is on the increase. In Holland, also, from whence a large quantity of the meat used in Britain is imported, it is not showing any sign of abatement; but in Belgium and France, where energetic measures were used at the outbreak of the pestilence, it has been got completely in hand. There is no ruler so good as an absolute monarch, provided he be a man of common sense, and in this respect the Emperor Napoleon on questions of a sanitary nature, such as the plague, deserves to be imitated by European potentates. He is equal to the position, and by his prompt and energetic action benefits his subjects generally before a committee or royal commission has agreed to hold its first meeting or appoint a secretary. A new view has been advanced with regard to the nature of the disease by Dr. Fenwick, who asserts from the experience of several post-mortem examinations that the disease is entozoic. He has found several patches resembling the so-called "measles" in pigs. Dr. Cobbold, in several letters to the daily journals, controverts the assertion that they are of an animal nature.

From the *Association Journal* we learn that M. Bouilly has been giving an account of the outbreak of rinderpest in the Jardin d'Acclimatisation before the French Academy. It broke out in two gazelles, which were purchased in England, and contracted the disease in a cattle-truck on the railway between London and Newhaven. M. B. does not seem to have observed all the symptoms; at all events, he calls the disease typhus, and does not allude to the eruption.

In the *Lancet*, Dr. Murelison has a very able article on the identity of rinderpest and small-pox. "There is nothing new under the sun," and it now turns out that this question engaged the attention of our ancestors three centuries ago, and at present is the view taken of a similar disease in Bengal. Dr. M.'s ideas appear to be borne out by some letters which are published from farms in different parts of England, whereas a letter from Dr. Fairmann, detailing a case of rinderpest which proved fatal to a cow "only recently recovered" from cow-pock, goes to prove the contrary; at any rate, the demand for vaccine lymph within the last ten days has been enormous; any of our readers of a sporting tendency will recollect the time it was the custom to vaccinate well-bred puppies to guard against the distemper.

In the *Lancet*, Dr. West gives the particulars of two cases of diphtheria, in which, during convalescence, paralysis of the muscles of deglutition occurred; in one case the patient was choked, the other died of inanition.

We are glad to see that amputation at the knee-joint is coming into vogue; at St. George's, Messrs. Pollock and Holmes, and at Guy's, Mr. Forster, have been operating in this way.

At the meeting of the Medical Society on December 18th, Mr. Lane detailed some cases at the Lock Hospital which were treated on Prof. Boeck's plan. Although he does not decidedly give in his adherence to the doctrine of syphilization, yet his success appears to be complete. The discussion on the subject was interesting. Our experience is not sufficient to warrant us in agreeing with the up-

holders of the doctrine, yet we must admit that Professor Boeck is a most accomplished scientific gentleman. He has been everywhere received almost with enthusiasm; he has upheld his views in moderate language, and never has lost his temper, showing that he acts not from mere personal motives, but from a love of investigating truth.

At the Pathological Society, Mr. Ernest Hart exhibited a case of cancer of the dura mater extending to the orbit. Mr. Ogle showed a brain from an insane patient studded with masses of calcareous deposits. In their annual report the Society deprecates the multitude of specimens for exhibition.

In referring to a recent complaint of neglect on the part of some of the officials at the London Hospital, reported in the *Times*, the *Lancet* has the following, which comes home to all of us —

"But the whole circumstance will serve usefully to remind those young men who act as dressers and house-surgeons in our hospitals during brief periods of office of the serious responsibility which devolves upon them in performing their duties. As a whole, the work is done with an earnestness and humanity which have ennobled our professional character. The work carried on in our public hospitals by the voluntary services of our medical officers and their unpaid assistants is one of the greatest and most practical labours of mercy to which in this age we can point. Individual instances of fault arising from want of thought will sometimes occur; they are greatly to be deplored, and do a vast amount of mischief. We earnestly commend to the serious consideration of these young men the injurious effect upon the reputation of all the officers of metropolitan hospitals which a single instance of such carelessness as that described may produce."

Dr. Cameron's able letter on the treatment of abscess in the acute hepatitis of hot climates by early incision, is in answer to Professor McClean, and a continuation of a former communication.

In the *British Medical* we have an excellent account of a case of recurrent military fever after scarlatina. The remarks on it and the disease in general is a masterly compilation of nearly all that is known on the subject.

Mr. Adams' paper, read before the South-Eastern Branch of the Medical Association, on the new methods of dealing with cataract, is a valuable addition to ophthalmic surgery. He has enjoyed unusual success in the Kent County Ophthalmic Hospital, where 116 cases were operated on in nine months. In 28 the needle operation for solution was employed, supplemented by the use of the suction curette. In 25 the linear extraction method was adopted with but two failures; there were 6 cases of iridectomy extraction, and 28 cases of flap extraction, with but one failure.

Dr. Thomas of Melbourne, describes three cases of long standing dislocation of the hip which were reduced; one of these was by Mr. Reid's manipulation method; in another case the patient was kept under chloroform for seven hours, when the reduction was effected.

The Venereal Commission, probably owing to the difficulty attending the process, it is believed will not recommend the periodical inspection of soldiers.

At the Manchester Medical Society, Dr. Samuelson detailed a case in which mercury was discharged by the skin in a metallic state.

In the *Medical Times and Gazette* there is an instructive case of injury of the head, followed by convulsions and paralysis, which did not come on for some time, and then quite suddenly. There is also a case of suspected poison-

ing by chloroform in a medical gentleman, who is supposed to have taken it in mistake for chloric ether.

At Guy's, Dr. Pavey has had a case of ulcer of the stomach opening the splenic artery and terminating fatally.

At St George's, Dr. Ogle has been treating chorea with Calabar bean, apparently with some success. It was given in half drachm-doses of the tincture prepared by the addition of a drachm of the bean to an ounce of spirit.

On the subject of chlorodyne the *Medical Times and Gazette* comes out in a leader; talking of its use among the ladies—

“For our own parts, we think a ‘bumper of Burgundy’ more honest, more pleasant, and quite as cheap in the long run as chlorodyne. We can't think a woman virtuous or delicate merely because she will not, in public, drink or eat enough to compensate for her fatigue or exhaustion of mind or body. If she shirks a glass of wine at dinner, and takes a dose of chlorodyne at night, we are inclined to think her a hypocrite.”

All the journals notice the baronetcy lately conferred on Prof. Simpson; there does not seem to be a second opinion on the subject, but that he has well earned his distinction. In that the honour has come unsolicited and after a considerable lapse time, during which chloroform has stood the test of age and fashion, it is more acceptable than a distinction hastily granted for services which may be soon forgotten, or the value of which may be negated by experience

EDINBURGH ROYAL INFIRMARY.

On Tuesday, 2nd January, the annual general meeting of the subscribers to the Royal Infirmary was held in the Council Chambers.

The Lord Provost, after explaining the object of the meeting, called on the secretary to read the annual report.

Mr Bell (the secretary) submitted the following report:—

The following is an abstract of the daily register of patients admitted during the year, from 1st October 1864 to 1st October 1865, showing the result of the cases:—Patients remaining in the hospital at 1st October 1864, 309; patients admitted from 1st October 1864 to 1st October 1865, 4590—total, 4899. Of these there were dismissed—Cured, 2781; relieved 817; with advice, or at their own desire 94; irregular or improper, 128; incapable of further benefit, 221; died in the hospital, 492—making a total of 4533. The number of patients remaining in the hospital at 1st October 1865 was 366. Of the cases treated to a termination during the year, 44 were cases of small-pox, 504 cases of fever, 2652 ordinary medical cases, and 1843 surgical cases. The average number of patients in the house during the year, according to the returns of the weekly census, was 393; the greatest number at any one time, 459; the lowest, 315; and the average time each patient remained under treatment was thirty days. In the year immediately preceding, the total number of patients under treatment was 4394; the average daily number, 386; the greatest number at any one time, 438; the lowest, 306; and the average time during which each patient remained under treatment was 31½ days.

Of the cases treated to a termination during the past year, there were:—From Edinburgh, 2696; from Leith and Newhaven, 246; from the country and other places, 1561.

The managers report with satisfaction a further decrease in the average period of residence, and they acknowledge with gratitude, as they have done on former occasions, the usefulness of the Convalescent Houses in relieving the Infirmary of patients the medical officers might have difficulty in discharging were they to return at once to their own homes, often at a very considerable distance. The contributors may remember that the managers mentioned in their report of last year, that a gentleman who proposes to raise a memorial to deceased relatives, had offered to do so in the form of a Convalescent House, to be in connexion with the Royal Infirmary, and that they had with much pleasure accepted of his generous offer. They have now the pleasure of informing the contributors that, the plans having been prepared and approved of, the building has been already commenced, and that on a scale and at a cost considerably greater than were contemplated when the offer was originally made.

The managers report with much satisfaction, that notwithstanding the large number of patients received during the last year, and the high prices paid for certain articles of maintenance, the expenditure has exceeded the ordinary revenue by only £14 2s. 6½d. It gives them much pleasure to report an increase of ordinary revenue of £863 8s. 9½d. over that of the year immediately preceding; and that pleasure is enhanced by their being able at the same time to report a decrease in the expenditure of £308 7s. 10d. While the subscriptions from Edinburgh are slowly but steadily increasing, those from country parishes have increased during the last few years in a most gratifying manner.

The expenditure of the Infirmary having, in recent years, exceeded the ordinary income to the extent of £1000 and upwards, the attention of the managers during the past year has been carefully directed to the object, and they are happy to be able to report that they have succeeded

to some extent in raising the revenue on the one hand, and in lessening the expenditure on the other. As regards income, the contributors to the Institution will observe that it has been increased from £13,190 2s. 7d. in 1864, to £14,054 11s. 4½d. in 1865, showing a net increase of £863 8s. 9½d. This augmentation has been reached as the result, partly at least, of special appeals made by the managers during the year, not only to the community generally, but also to the operative classes, who so largely partake of the benefits of the Institution. The increase from this latter source amounts to £234 8s. above the sum contributed during the previous year; and from the measures which have been adopted to enlist the sympathies of the operatives, the managers entertain the hope of realising a still larger augmentation during the current year. From personal subscriptions in town and country, there has been an increase of £465 3s. 8½d.; and it is gratifying to note, more especially as regular yearly contributions may be expected from the same quarter in future, that this amount includes £73 7s. 6d. remitted from the most northern counties of Scotland—namely, Caithness, and Orkney, and Shetland. In relation to expenditure, it will be observed by a reference to the report, that the amount of disbursements during last year was £14,067 11s. 10½d., while, in the previous year, it was £13,376 1s. 8½d., showing a difference in favour of the former of £308 7s. 10d. It is proper to add that the surplus would have been much greater had there not been a considerable amount of extra expenditure throughout the year, arising from—first, additional patients, numbering 248; and, secondly, the greatly increased price of butcher's meat, and leaving out of view items of less amount, from charges for cleaning and painting to an extent very much above the average of former years. These three items combined have added to the expenditure during the past year more than a thousand pounds.

The managers derive encouragement from what has been already done to lessen the expenditure, to continue their exertions in the same direction during the current year, and are not without hope of effecting further reductions. At the present time they are making careful inquiry into the whole items of expenditure, having had very extensive returns laid before them by Mr. Russell, one of their number, enabling them to compare it with that of many other hospitals in various parts of the kingdom. From these it appeared that though the expenditure of the Edinburgh Royal Infirmary was much below that of the chief hospitals in London, in proportion to the number of patients treated, it was yet considerably higher than that of Glasgow. The managers, therefore, desiring more full information, appointed a deputation of their number to visit the Glasgow Infirmary.

SIR JAMES Y. SIMPSON, BART.

THE bestowal of an honour by the Crown seldom calls forth such universal and most hearty congratulation as has been manifested throughout the kingdom when it became known that Dr. Simpson had been created a baronet. To himself it must be a cause of just pride; that the Queen has deemed his exertions to advance the progress of medical science in the departments of physic midwifery, and operative surgery, worthy of some recognition from the Crown, and to the whole profession throughout the world, but especially to the medical practitioners of Scotland, it must be gratifying to feel that in thus honouring one of their most illustrious members, Her Majesty has also paid a handsome compliment to them.

The cheers and congratulations which have greeted Dr. Simpson's appearance during the last week in his class at the University, and in the numerous learned societies, of which he is a member, show that the universal feeling is that the honour is well deserved. That he may be spared long to wear his honours, and advance the science of medicine is the hearty wish of the whole country.

DR CARPENTER presents his compliments to the Editor of the *MEDICAL PRESS AND CIRCULAR*, and is desired by the Senate to request the insertion of the accompanying Letter, which has been transmitted to the several Medical Schools in connexion with the University.

University of London, Burlington House, W. Dec. 25, 1865.

SIR,—The Senate of the University of London having had their attention drawn to the large number of failures which have annually taken place among the candidates presenting themselves at the Preliminary Scientific M.B. Examination, and especially to the results of the Examination in July last (when 43 out of 75 candidates were rejected), have thought it expedient to place before you the following statement of their purpose in instituting this Examination, and of the mode in which they desire that this purpose should be carried out.

It is the opinion of the Senate that no system of medical education can be regarded as sound and complete, which does not ensure on the part of the student who is entering upon a course of professional study, such an aptitude of

mind as shall enable him fully to profit by it, as well as the possession of such an amount of general knowledge as shall supply a basis for his future acquirements. With this view they have from the first insisted upon the Matriculation Examination as the fundamental condition of medical graduation in this University. And it has been more fully to secure the same object, that they instituted five years ago the Preliminary Scientific Examination,—detaching from the First M.B. Examination the subjects of inorganic chemistry and botany which were previously included in it, and combining with these the additional subjects of mechanical and natural philosophy, and zoology.

A knowledge of the general doctrines and leading facts of physics and chemistry, and of the principal types of organization presented by the animal and vegetable kingdoms, is regarded by the Senate as essential to any one who would prosecute the study of the human organism in health and disease, and of the influence of external agencies upon it, in an enlarged philosophical spirit.

But they attach no less importance to the mental discipline by which the mind of the student is prepared, through that training in habits of correct observation and precise reasoning which the careful study of the physical and natural sciences involves, for dealing with the complex problems presented to him in the study and practice of medicine. And with these views they have so framed the scheme of examinations, that it shall embrace in each of the subjects those *details* which are most important to the student of medicine, whilst it shall test the mastery of *general principles* which the candidate has acquired, and his power of applying them.

Whilst limiting, by the detailed programmes contained in the regulations, the range of examination in each subject, the Senate feel it right to expect that the candidates knowledge within that range should be full and precise; since either deficiency or inaccuracy, presenting itself to any considerable degree, shows that the objects with which this test is imposed have not been fulfilled. And the Senate attach special importance to the *practical* parts of this examination, as affording the most satisfactory evidence how far the candidate has really profited by the course of study he has gone through.

The results of the last Preliminary Scientific Examination show that it is in the subjects of *botany* and *zoology* that the candidates have shown the least proficiency; for when out of the 43 candidates who failed, 16 were rejected in chemistry, 8 in mechanical philosophy, and 16 in natural philosophy, no fewer than 39 were rejected in botany, and 32 in zoology—4 of these rejections being in botany, and 3 in zoology alone.

The candidates who were rejected in botany, whilst showing an insufficient knowledge of vegetable physiology, especially failed in their descriptions of the plants placed before them. This exercise is regarded by the Examiners in botany as the best evidence of the candidate's knowledge of the fundamental facts of vegetable organization: whilst it is looked upon by the Senate as one which can only be effectually prepared for by the acquirement of those habits of correct and discriminating observation, of systematic arrangement and accurate record of the facts observed, which they regard as constituting a most valuable preparation for his whole subsequent career as a student and practitioner of medicine.

I am directed, therefore, to express the hope that candidates who may hereafter present themselves from your school may show themselves thoroughly trained in this elementary part of the subject; on which the Senate deem it right to insist far more than they do on a knowledge of the distinguishing characters of the natural orders—which will only be required where these orders represent great fundamental types of organization.

The case is different, however, with regard to the animal kingdom; since the knowledge on which the Senate feel it requisite to insist, is that of the "distinctive characters and chief peculiarities" of each of the great groups under which the members of that kingdom are now classified. It will scarcely be disputed that the student who has mastered these will enter upon the study of human anatomy and physiology at a great advantage, as regards both the value of the knowledge he has attained, and that of the mental training he has gone through in its acquirement. The Senate do not consider that this knowledge can be *real*, unless the candidate has gained it from *specimens* at least as

much from *books*; and with this view they regard it as essential that it should be tested by a practical examination. The experience of this examination has shown so lamentable a deficiency of such knowledge on the part of a large proportion of candidates, that I am directed respectfully to urge it upon you as essential to the success of candidates at this examination, that they should have access to a museum containing *typical specimens* of the several groups enumerated in the regulations, and of the principal subdivisions of these; and that they should so thoroughly familiarise themselves with them, as to be able to correctly refer any similar specimens to their proper places in the zoological series.

It is with great satisfaction that the Senate have observed, in the results of the recent second M.B. Examinations, the efficacy of the new regulations which the introduced five years ago, in raising the standard of professional acquirement on the part of the candidates who have been trained under them. At the second M.B. Examination of November 1864, 27 candidates presented themselves, of whom only 1 failed and 20 passed in the first division. And at the second M.B. Examination which has recently taken place, 24 candidates presented themselves, of whom 1 withdrew and 19 passed in the first division—the Examiners expressing themselves strongly as to the high standard of merit which was shown by the majority of these. No fewer than 15 subsequently presented themselves at the examination for honours in medicine, and 14 were placed in the first class, 6 of these being reported by the Examiners as having shown a degree of proficiency which rendered them deserving of the scholarship.

It thus appears not only that the candidates who are deficient either in natural aptitude or in steady application are eliminated by the Preliminary Scientific and first M.B. Examinations; but that those who have succeeded in passing these examinations have received a culture and undergone a discipline of the greatest advantage to them in the prosecution of those purely practical studies which occupy the latter portion of the University curriculum.—I have the honour to be, Sir, your most obedient, servant,

W. B. CARPENTER, Registrar.

To the Secretary of the Medical School of—

NOTICES TO CORRESPONDENTS.

"A Naval Surgeon," Dublin.—Is thanked for his kindness; he will find the other subjects to which he alludes, mentioned in the letter of our London correspondent.

"G. P. R., M.D.," London.—We do not decide bets in this journal, but for the honour of our country we claim Mr. Francis Kiernan, the late Vice President of the London College of Surgeons, as an Irishman. Mr. Quain, his colleague, also belongs to this country.

"A Traveller."—Consult Dr. Madden's Travels in Turkey.

"H. S., King's College."—Dr. H. R. Reynolds, who attended George III during his afflicting and protracted malady, was one of the last of the school. He wore a well-powdered wig and a silk coat, and was an excellent specimen of the well-dressed and well-bred gentleman. The following lines are by Wadd, of facetious memory:—

"Here well-dressed Reynolds lies,
As great a beau as ever!
We may, perhaps, see one as wise,
But sure, a smarter, never."

"A Student, Middlesex Hospital."—Plumket's Caustic was discovered and used most extensively, and it is said successfully, in certain cases of cancer, by a poor man of the above name, in the county of Wicklow. Sir Charles Blake used it extensively.

"A Fellow."—The earliest work published on the plan of the "Medical Directory" appeared in 1779, and ceased to exist in 1781. It was called "The Medical Register."

"A Student," Cork.—The preliminary examination of the Apothecaries Hall, Dublin, now exempts you from that ordeal at the London College.

"Dr. M. Liverpool."—We thank you for your good opinion, which we hope we shall continue to deserve.

"X. Y. Z."—Comparisons are odious, and we do not intend to make any. We think both the gentlemen in question are well entitled to the honour. "Et vitula tu dignus et hic."

"A Provincial Student."—The operating day at King's College is Saturday, and that at St. Bartholomew's is the same. Mr. Lawrence has retired from the Surgery of the latter Hospital, but he retains his seat at the Council Board and at the Examining table of the College of Surgeons.

"M. B. Cantab."—The degree of M.D. at the University of London can be obtained only by examination.

"The Obstetrical Society of London."—The Report has been received.

"Mr. Griffin."—The letter has been received.

"Mr. Neil McGroovy."—The letter has been received.

"Dr. H."—We think that the charge was quite moderate under the circumstances mentioned.

"Mr. A. H."—We do not advise you to bring an action without fully weighing all the probable consequences.

"Dr. J. Milson, Castleton."—Dr. Taylor's Principles and Practice of Medical Jurisprudence, price 2s., or the Manual of Medical Jurisprudence, by the same author, price 12s. 6d.

REPRINTS OF CONTRIBUTIONS.

CONTRIBUTORS to "THE MEDICAL PRESS AND CIRCULAR" are informed that their communications can be reprinted in book form at a very moderate cost immediately after they have appeared in the Journal. It being assumed that the contributions have been properly corrected and revised before publication in the Journal, and great delay and no little expense having been incurred in consequence of alterations made subsequently to publication, it is notified no proofs can in future be sent out, or alterations made in the matter, before reprinting. The rates of charges for reprinting will be forwarded on application at the office.

Mr. Langley's and Harris's advertisements did not reach us sufficiently early to be attended to this week.

THE GRIFFIN TESTIMONIAL FUND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The following subscription has been further received on behalf of the above fund:—

Dr. Hutehinson (Bishop of Auckland)	£0 10 0
Amount previously announced	132 4 3
Received at "Lancet" office	9 9 0

—Yours obediently,
145, Bishopsgate-st., Out, Jan. 10, 1896.

ROBERT FOWLER,
Treasurer and Hon. Sec.

HARVELAN SOCIETY OF LONDON.

W. TYLER SMITH, M.D., President.

The following arrangements have been made for the second half of the Session:—

January 18th.—Dr. Drysdale, "On the Medical Aspects of Prostitution."

February 1st.—Mr. Victor de Meric, "On Syphilization."

February 15th.—Dr. Camps, "On Railway and other Accidents attended with Violence: their Effects on the Nervous System."

March 1st.—Dr. Broadbent, "On Prognosis in Heart Disease."

March 15th.—Dr. Meredith, "On the Duality of Venereal Ulcers."

April 5th.—Debate, "On Rheumatism and Gout."

April 19th.—Dr. H. C. Stewart, "Some further Remarks on Embolism of the Great Vessels of the Heart."

May 3rd.—Mr. Berkeley Hill,

May 17th.—Debate, "On Infantile in its Medical and Social Bearings."

The Chair will be taken each Evening at Eight o'clock precisely.

J. BRENDON GURGENSEN,
CHAS. R. DRYSDALE, M.D.,

MEDICAL APPOINTMENTS.

N. Avent, M.R.C.S.E., has been elected Medical Officer and Public Vaccinator for No. 2 or Wallham-green District of the Pulliam Union, vice C. M. Meller, M.D., resigned on account of ill-health.

J. Barker, M.D., has been elected a Member of the Court of Examiners of the Royal College of Surgeons in Ireland, vice J. Morgan, F.R.C.S.I., deceased.

J. J. Barrett, M.D., has been elected District Surgeon to visit Out-patients to the Royal South London Dispensary, St. George's-cross, Lambeth, vice J. Tanner, M.D., resigned.

J. W. Barrett, M.R.C.S.E., has been elected Medical Officer and Public Vaccinator for the 1st North-Western District of the Freebridge Lynn Union, Norfolk, vice W. S. Black, M.R.C.S.E., resigned.

J. B. Bramwell, M.D., has been appointed to the Commission of the Peace for the Borough of Tynemouth.

E. Chaffers, M.R.C.S.E., has been appointed Assistant-Surgeon to the North Riding Lunatic Asylum, Clifton, York, vice J. T. Hingston, M.R.C.S.E., elected House-Surgeon to the Northampton General Lunatic Asylum.

M. Charteris, M.D., has been elected Assistant Medical Officer to the Parishes of St. Giles and St. George, Bloomsbury, vice Wm. Cribb, M.R.C.S.E., resigned.

T. Clark, M.D., formerly Professor of Chemistry in Marischal College, University of Aberdeen, has been appointed by John Stuart Mill, Esq., M.P., Rector of the University of St. Andrew, to be his Assistant in the University Court.

W. T. Crawford, M.D., has been appointed Medical Officer for District No. 2 of the Great Ouseburn Union, Yorkshire, vice H. Langdale, L.S.A.L., resigned.

B. G. Genham, M.R.C.S.E., has been elected Medical Officer and Public Vaccinator for the Ederney Dispensary District of the Irvinestown Union, County Fermanagh, vice W. Johnson, M.R.C.S.E., resigned.

W. Hignmore, M.D., has been appointed one of the Medical Officers to the Yeatman Hospital, Sherborne, Dorsetshire.

W. T. Hudson, M.R.C.S.E., has been appointed Medical Officer for the Southern District of the Parish of St. James, Clerkenwell, vice J. Bryant, M.R.C.S.E., resigned.

E. Jones, M.D., of Mount Craig Ross, has been qualified as one of her Majesty's Justices of the Peace for the County of Hereford.

J. G. Mackinlay, L.R.C.P.L., M.R.C.S., has been appointed Resident Medical Officer to the Charing-cross Hospital, vice Wm. Travers, L.R.C.P.L., F.R.C.S., resigned.

S. E. Proctor, L.R.C.P.Ed., has been elected Medical Officer for Districts Nos. 7 and 8 of the Tonbridge Union, vice A. Monckton, M.R.C.S.E., deceased.

J. L. Probert, M.R.C.S.E., has been appointed by the Metropolitan Board of Works Surgeon to the A Division of the Metropolitan Fire Brigade.

R. Ransom, M.D., has been appointed Medical Officer to the Union Workhouse, Cambridge, vice J. T. Beck, M.R.C.S.E., resigned.

W. S. Saunders, M.D., has been appointed Surgeon to the B Division of the Metropolitan Fire Brigade.

J. Tatham, M.D., has been elected one of the Honorary Medical Officers of the Royal Pimlico Dispensary, Upper Belgrave-place, vice J. Frodsham, M.D., resigned.

W. H. Williams, M.D., has been appointed one of the Medical Officers to the Yeatman Hospital, Sherborne, Dorsetshire.

W. T. G. Woodforde, M.D., has been appointed Surgeon to the C Division of the Metropolitan Fire Brigade.

MEDICAL VACANCIES.

Belfast General Hospital.—House-Surgeon and Superintendent.
Bridgewater Union (Chilton Polden District)—Medical Officer.
City of London Lunatic Asylum.—Assistant Medical Officer.
Criminal Lunatic Asylum, Broadmoor.—Assistant Medical Officer.
Liverpool Northern Hospital.—House-Surgeon.
Raddcliffe Infirmary.—Physician.
St. Pancras Workhouse.—Resident Assistant-Surgeon.
Wilton Union (Bishopstone District)—Medical Officer.

BIRTHS.

On the 21st ult., the wife of S. Plumbs, M.D., of Maidenhead of a daughter.
On the 29th ult., at Hanover-square, Dartmouth, the wife of Dr. A. Newnan, Mayor of Dartmouth, of a daughter.
On the 30th ult., at Harley-street, Cavendish-square, the wife of Dr. Hyde, Salter M.D., of a son.
On the 31st ult., at Rochester, the wife of Dr. Frederick James Brown, of a daughter.
On the 1st inst., at Stainston Lodge, Blackheath, the wife of Dr. R. Finch, M.D., of a son.
On the 6th inst., at Royal-terrace, Weymouth, the wife of James Lithgow, M.D., of a daughter.
On the 7th inst., at Fen bury-place, the wife of Dr. Palfrey, of a daughter.
On the 10th inst., at Risca, Monmouthshire, the wife of Richard Estance, M.R.C.S.E., of a daughter.
On the 10th inst., at Botley, Southampton, the wife of J. C. Harris, M.R.C.S.E., of a daughter.

MARRIAGES.

On the 4th inst., at Georgeville, Irvine, Robert Dunlop, M.D., to Mary daughter of Capt. James Brown.
On the 8th inst., at Windmill-hill House, Dalziel, Lanarkshire, William Whamond, M.D., of Janow, Durham, to Mary Ann, eldest daughter of Mr. Thomas King.

DEATHS.

On the 30th ult., W. R. Hatrick, M.D., of Glasgow.
On the 1st inst., Andrew Sisson, M.R.C.S.E., of Reigate, Surrey, aged 56.
On the 4th inst., E. Guest, F.R.C.S.E., of Halsey-street, Chelsea, aged 49.
On the 4th inst., at Buckingham-square, Govan, Mr. J. S. Mair, Medical Student, aged 20.
On the 5th inst., at Brynfydwyn, Treherbert, William Edward, son of Dr. Wm. Evans, aged 19 months.
On the 7th inst., Henry Payne, M.D., of Nottingham, aged 80.

LECTURES

ON THE NATURE, CAUSES, AND TREATMENT OF DYSPEPSIA.

Delivered at the
QUEEN'S HOSPITAL, BIRMINGHAM.

By BALTHAZAR W. FOSTER, M.D., F.L.S.,

MEMBER OF THE ROYAL COLLEGE OF PHYSICIANS, LONDON;
LICENTIATE OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND; PHYSICIAN TO THE QUEEN'S HOSPITAL AND PROFESSOR OF CLINICAL MEDICINE IN QUEEN'S COLLEGE, AND OF THERAPEUTICS AND MATERIA MEDICA IN SYDENHAM COLLEGE, BIRMINGHAM.

LECTURE II.

GENTLEMEN,—In considering the pathology of dyspepsia, we shall attach much importance to that portion of the subject which relates to the causation of the disease under our notice. Etiology forms a very necessary and important part of general pathology, but it is only in relation to special diseases that it has been carefully investigated, and the study has produced much that can aid us, not only in diagnosis, but in treatment. The disorders of digestion afford a good example of the benefit of this kind of inquiry, and on the soundness and completeness of our knowledge of their causes will depend in a great measure our skill in recognizing and our success in treating them. For depending, as these disorders mostly do, upon no marked or permanent lesion of structure, and being happily nearly always susceptible of cure, the recognition and removal of the causes generally goes far towards effecting the restoration of health. The complex character of the digestive act, the intimate connexion and sympathy of the stomach, through its nerves, with other parts of the system, and the great variety of irritants to which it is ordinarily exposed, render the study of the causes of dyspepsia, however, no easy task.

In similar inquiries into the causation of disease it has been found most convenient to arrange all causes under two heads in accordance with their more remote or more immediate connexion with the production of the malady. We shall, therefore, first consider the remote or predisposing causes, and under this head it will be well for us to dwell briefly upon the influence exercised by *age, sex, constitution, social condition, and climate.*

Age.—The first meal that enters the stomach may be a source of difficult digestion, so in early life we find gastric disorder no infrequent malady. It is, however, in children artificially fed that we see indigestion most frequently, although children fortunate in the enjoyment of their natural food are not always free from it. This is not surprising when we consider the delicacy of the organ involved, and the great and almost constant tax made upon its powers to supply materials for the growth of the rapidly changing tissues. The troubles of teething also act as predisposing causes. The dyspepsias of infants are, however, usually slight, and may be referred for the most part to the class of accidental dyspepsias.

In youth, especially in the strumous and ill-fed inhabitants of towns, the liability to digestive derangement is marked. At this period, from a want of due attention

to diet (for at no time of life are more indigestible and hurtful substances devoured), and in some cases, from the original weakness of the assimilative organs, indigestion is no uncommon complaint, and if not checked, too often initiates changes which lay the foundation of future tuberculosis. The middle period of life is open to all forms of difficult digestion, and we find that at this period (from 21 to 50) the malady most frequent—a fact which is to be explained by the greater exposure to the exciting causes at this time.

In the old the troubles of the digestive organs are not, as might be expected, more frequent than in middle life; on the contrary, especially in the upper classes, they are less numerous. This no doubt is due to the fact that the approach of old age has brought with it a cessation from the more absorbing and active duties of life, and has thus given to each one a greater amount of leisure for self-study. This self-study, rendered more acute by the stimulus of the universal desire to prolong existence, leads each one to exercise an amount of abstinence and regularity with regard to diet that diminishes much the occurrence of dyspepsia, and has made proverbial the almost medical care with which old persons regulate their food.

Sex.—Man, by reason of his habits and his occupations, would at first sight seem to be more predisposed to gastric difficulty than woman, but the highly nervous temperament and the peculiar functions of the female sex counterbalance this apparently greater predisposition in the male. Menstruation, lactation, and child-bearing, render woman obnoxious to many forms of dyspepsia, but chiefly to the more transitory varieties, while her moderation in the pleasures of the table and her comparative freedom from many of the vices of the other sex, enable her to escape the more serious and intractable forms of the disease which we find mostly in man. One habit, and that happily one likely soon to disappear from among the women of our own country—I allude to tight-lacing—is still found occasionally to be active as a predisposing cause of difficult digestion.

Constitution.—Weakness of constitution, especially when connected with the nervous temperament, strongly predisposes to dyspepsia, as is illustrated by the frequency of such disorder in the female sex, in whom this combination of temperament and habit is most commonly observed.

Hereditary predisposition is asserted by many to exist, but from the common occurrence of the affection and the variety of causes to which it may be referred, it is unnecessary to add this one to the many causes of dyspepsia. In the inheritance of a peculiar diathesis, such as the rheumatic, exist, in our opinion, the explanation of such cases as have been termed hereditary dyspepsia. In the out-patient room we have constantly seen together the special forms of gastric disorder associated with certain diatheses, so that with many of our patients, from our knowledge of the constitutional tendency, we gain much useful information in the treatment of the malady. I need scarcely add that we constantly see these peculiarities of habit of the parent appearing in the child.

The introduction also of certain poisons (of lead, mercury, syphilis, &c.) into the system give rise to difficulties of digestion, not only by means of the cachexia they induce, but in some cases by their special effects upon the assimilative organs.

In females the chloro-anæmic state, associated as it is with so great disorder of the mucous membranes, has connected with it very often a serious form of indigestion that often remains long after the original disease has yielded to treatment.

Debilitating influences (to which I can only allude) connected with the generative system, especially in young persons about the age of puberty, favour in a marked degree the production of a painful form of gastric neurosis.

The opposite condition of plethora, occurring more especially in the middle-aged, is by no means void of influence in the production of stomach disorders.

Social Condition.—In speaking of the social causes of dyspepsia, I include not only those which are connected with our present state of civilization, but also those which depend upon professional or business avocations. The history of each civilization that has preceded our own contains abundant proof that the vices and habits hitherto ever attendant on advanced social condition, have conduced strongly to the development of all kinds of disordered function in man. In the present day, among some we find that the long-continued labour necessitated by the struggle for existence in others, the absorbing character of their pursuits, and in a third class the thoroughly artificial conditions of life, all producing one effect—a great tendency to neuroses. It is well known that at periods of great public excitement diseases of the class to which dyspepsia belongs are very much more frequent, and the conditions of life in all our large towns are certainly great promoters of these diseases in the present day. In spite of the greater moderation in the pleasures of the table which prevails now, when compared with former periods, one must admit that our habits in many respects are more unphysiological than those of our forefathers.

Some occupations predispose to digestive difficulties by acting through the general system, producing a cachexia, as, for example, the trades which necessitate working with lead, mercury, or arsenic. Others, without being directly injurious, may be opposed to the laws of health. Thus I may enumerate all trades which expose their followers to an elevated temperature, as furnace-keepers, glass-blowers, and bakers. Those who in plying their business are constrained to occupy one position for several hours at a time are very prone to dyspeptic derangements, and those who, in addition, during their work are subjected to any pressure over the stomach capable of interfering with its necessary movements, are most frequently attacked. Clerks, tailors, shoemakers, and engravers, &c. &c., on this account afford us many examples of dyspepsia. In the pursuits dignified by the title of professions we cannot select one more calculated to bring about disordered digestion than that of the over-worked member of our own class. In his case want of proper repose, irregularity of meals, exercise soon after eating, prolonged fasting, no ordinary amount of care and anxiety, added to a large share of intellectual activity, form an assemblage of conditions which, were they not neutralized by a great knowledge of disease, would, by frequently invoking grave gastric troubles, materially shorten the already limited lifetime of the follower of our art. In many other professions (e.g. letters) we find conditions eminently favourable to the production of these maladies, but in none so many as our own.

Climate.—Warm climates exercise considerable influence over the digestive organs. The warmth of our summer produces a certain effect upon us, and we find that any excess is at this season more surely followed by indigestion than in the colder months. Our countrymen when in warmer climates soon experience loss of appetite and weakness of digestion, symptoms which, if the desire for food be stimulated by condiments, as is too often done, soon passes into serious dyspepsia. The diminished activity of the skin and liver, produced by an elevated temperature, indicate to some degree the mode in which the digestive organs are affected. Even in the natives of hot countries we find a predominance of the nervous and bilious temperament; the production of indigestion among workmen exposed to great heat, to which we have already alluded, is interesting in connexion with this question. The opposite condition of cold and damp has also an ill-understood, but nevertheless material, influence on the production of the diseases under notice. We know that in cold and moist climates a depressed condition of the vital powers prevails, and with it a loss of functional energy, to which we may attribute fairly the prevalence of dyspepsia. The use of alcohol is general in cold and damp countries, and is indicated in moderation as a means of

meeting the functional atony, common under these climatic conditions.

It will be our duty to pass on now to the consideration of the circumstances which are more closely related to the production of stomacual disorders, and which we may speak of as the *exciting* or *determining* causes. The study of this part of the etiology of our subject will naturally prove more interesting, because our knowledge of these conditions is more exact. The best method we can follow in the investigation of these causes will be to consider—1. individual conditions; 2. diet; 3. the digestive process. In carrying out this plan it will be necessary to speak under the first head of habits and idiosyncrasies; then to discuss the question of diet, and to point out how dietetic errors become causes of disordered action; and, finally, to review the digestive act, and to see how abnormality in any of its various stages may determine the production of dyspepsia. The consideration of individual conditions will lead us to dwell briefly upon *habits* and *idiosyncrasies*, and also to refer to what may be spoken of as the *moral causes* of indigestion. The use of ardent spirits in excess may be mentioned first of all as the most pernicious habit which produces these maladies.

It would be out of place here to enter upon the vexed question of the action of alcohol on the economy at large, we shall, therefore, only refer to its use as a cause of difficult digestion. When taken in large quantities by a person unaccustomed to it, it produces an attack of accidental dyspepsia, and when it is habitually taken in excess it gives rise to a well-marked form of chronic dyspepsia. Among certain classes of our population the custom of taking frequently small quantities of alcohol on an empty stomach, is lamentably common and productive of the most serious effects. The use of alcoholic fluids at meals is less injurious, for then its chief action is to delay, and in many cases to prevent, the digestion of the food; but on an empty stomach it acts as a stimulant to the lining membrane of the organ, producing, when taken in a small quantity, an increased secretion of gastric juice, but when frequently repeated in larger doses it becomes an irritant of the most hurtful kind. Of the various forms of ardent spirits rum may be considered the least hurtful, gin and brandy the most so. The injurious effect of wine is mainly in proportion to the amount of the contained alcohol; the same may be said of the various forms of beer and porter; but we must remember that these contain many principles by which they may claim the title of foods. Cider is less nutritious than beer, and often contains more alcohol, and its abuse we consider generally more hurtful. The habits of smoking and snuff-taking we may enumerate as often productive of digestive difficulty. Tobacco smoking is injurious only when indulged in to excess; to most individuals its moderate use is a harmless luxury. Its abuse is injurious by the exaggerated flow of saliva which it causes, as well as by the absorption of a greater or less quantity of the active principle of the tobacco. This principle is not only directly hurtful to the mucous membranes but also prejudicial by its indirect action through the nervous system. Snuff-taking, as a habit, has all the evil effects of smoking, and in addition to the modes in which the latter produces its deleterious action the contact of the snuff with the mucous membrane interferes greatly with healthy secretion. Habits which interfere with that mental and bodily repose after meals, so necessary to happy digestion, are especially injurious, and in many cases you will find a dyspepsia of long standing may be removed by attention to this point. Bathing either in hot or cold water I may also mention as being contraindicated after the ingestion of food. The ignorance or neglect of this often produces attacks of indigestion of the gravest form.

In speaking of idiosyncrasies I might detain you long, for the subject is full of curious interest, but it will suffice to devote a few remarks only to the consideration of these individual peculiarities. I must premise, however, that we believe less in these antipathies to certain forms of

food than formerly, and that they should only be admitted in any case after the most searching examination, for oftentimes they are due to functional disorder. The advance of chemistry and physiology we may expect will enable us to further limit these eccentricities of the digestive organs. Sometimes it is any kind of fish that thus disagrees is quickly rejected from the stomach. In some cases it is a particular kind, such as lobsters, oysters, or salmon that causes the digestive difficulty. Many fruits thus affect some persons, as, for example, peaches, oranges, and even a single strawberry has been known to produce considerable gastric derangement. Eggs, mutton, hare, and many other articles of food might be mentioned which are almost poisonous to some persons, and a peculiarity often to be remarked is that these noxious substances are often expelled *alone*, either by vomiting or by defecation, the stomach in such cases, as Chomel has observed, being endowed almost with an "elective action" by which it separates these materials from the remainder of the alimentary mass. Temporary idiosyncrasies are often met in female patients during the period of gestation, and at this time you will find all peculiarities of the kind under notice most marked. In speaking of the moral causes of dyspepsia I need not detain you long. We all know the intimate connexion that exists between mental action and digestive work, and the frequent occurrence of indigestion from great emotion will often present itself to you in practice. As contentment and joy are conditions favourable to digestion, so sorrow and fear, and like emotions, greatly interfere with, nay, in some instances, actually stop the digestive act.

TEMPERATURE OF THE BODY IN FEVER.

No. I.

By THOMAS WRIGLEY GRIMSHAW, A.B., M.B.Dub.,
PHYSICIAN TO CORK-STREET FEVER HOSPITAL, LECTURER ON MATERIA
MEDICA IN DR. STEEVENS' HOSPITAL.

THE following report of the results of observations on temperature in cases admitted into Cork-street Hospital, may not be without interest at the present time, when the temperature of the body in disease is attracting so much attention. In most of the following cases the temperature and pulse have alone been noted, but in all cases at present under observation the rate of respiration is also being recorded, so that in future when I may have the honour of continuing these reports in THE PRESS, I shall have more complete records to lay before your readers. The observations in these cases have been registered but once a day in each case, my reason for not having taken them oftener being, that I do not consider it of much practical importance, for in using the thermometer as a constant means of assisting our diagnosis, it would generally be impracticable to examine our patient's temperature more than once daily, just as we usually employ our stethoscope but once in twenty-four hours on each case. The fact is, it is only when a case has become serious that we give it two or more visits a day. The object of making these observations, upon which I am now reporting is to test the value of the thermometer as a practical help to the formation of our diagnosis, and not merely as a means of scientific inquiry. I am afraid the value of the thermometer as a means of diagnosis, has (at least in a fever cases) been much overrated, but I shall refrain from drawing conclusions, until I have finished my report of the observations which I am at present conducting.

The cases upon which these observations have been made have been all under the care of Dr. Henry Kennedy, many of them during the whole period of their treatment.

Case 1.—Elizabeth C., admitted December 21st, 1865,

age 22. Ill eight days before admission; brown tongue and all the symptoms of typhus, but no eruption.

	Pulse.	Temperature Fahr.
December 21	120	103.75
" 22	116	103.75
" 23	116	103.50
" 24	120	102.50
" 25	120	103.50
" 26	112	103.00
" 27	108	101.50
" 28	108	102.50
" 29	84	101.5
" 30	84	98.25
" 31	96	103.00
1866—January 1	84	99.00
" 2	84	98.00
" 3	84	97.50
" 4	130	not taken.
" 5	84	98.25
" 6	60	98.50
" 7	80	97.75
" 8	80	98.50
" 9	72	98.00
" 10	84	102.00
" 11	70	98.00

Convalescent.

The points to be remarked in this case are, it was apparently a pure typhus case *without* spots. On January 4th, the patient got up, contrary to orders, the pulse rising to 130, but the temperature was not tested; on January 10th, the temperature rose to 102°, although for some days it had been normal. On this day the patient complained of pain in the abdomen and confined bowels, which were relieved by a dose of purgative medicine, the rise in temperature not being accompanied with equivalent rise in pulse, nor sufficient decrease to account for the great increase of heat.

Case 2.—Teresa S., admitted December 21st, 1865, age 26; six days ill before admission; complains chiefly of weakness. There appeared to be a slight mottling of the skin, of which, however, there was no trace the following morning.

	Pulse.	Temperature.
December 21	112	102.00
" 22	120	101.50
" 23	108	102.00
" 24	112	101.75
" 25	108	101.25
" 26	88	102.00
" 27	84	101.00
" 28	84	101.75
" 29	100	100.00
" 30	120	99.00
1866—January 1	88	100.00
" 2	84	99.00
" 3	84	97.50
" 4	108	99.00
" 5	84	98.00
" 6	80	98.00

Convalescent.

The range of temperature in this case is remarkable, as the patient exhibited no other symptom of departure from health. The thermometer alone would have caused an erroneous prognosis.

Case 3.—Martha S., admitted December 23rd, age 60. Ill eight days before admission. Large dark maculæ very numerous; tongue dark-brown and very dry.

	Pulse.	Temperature.
December 23	132	103.00
" 24	104	102.00
" 25	132	102.50
" 26	124	101.50
" 27	132	100.50
" 28	Impereceptible	95.00

Died at twelve noon on December 28th.

In this case the sudden and extended fall in temperature on the day of death is remarkable.

Case 4.—Thomas H., admitted December 23rd, 1865. Ill three (?) days before admission; densely maculated.

	Pulse.	Temperature.
December 23	104	100.50
" 24	112	101.00
" 25	120	102.50
" 26	116	104.00
" 27	110	101.00
" 28	110	102.50
" 29	120	100.50
" 30	108	102.50
" 31	96	100.50
1866—January 1	100	99.50
" 2	88	99.50
" 3	90	100.00
" 4	76	98.50
" 5	70	99.00
" 6	84	98.00
" 7	84	98.00
" 8	84	98.00

Convalescent.

In this case the rise in temperature on December 25th and 26th is to be remarked. On the latter day pneumonia of the base of the right lung was discovered, to which the rise in temperature may be fairly ascribed.

Case 5.—Amelia G., admitted December 28th, age 57. Ill eleven days before admission.

	Pulse.	Temperature.
December 28	144	103.00
" 29	132	101.00
" 30	120 (?)	102.25
" 31	140 (?)	99.00
1866—January 1	Imperceptible	99.00
" 2	"	99.50

Died.

It is to be remarked in this case, as in Case 3, that there was a sudden and extended fall of temperature immediately before death. The temperature of the skin in this case although high did not give such a sensation to the touch, therefore the thermometer was of great value in ascertaining the real condition of the patient.

Case 6.—John L., admitted December 27th, age 18. Ill five days before admission; has many symptoms of commencing fever.

	Pulse.	Temperature.
December 28	84	99.00
" 29	84	Not taken. Patient up.
" 30	68	98.00
" 31	64	99.00
1866—January 1	84	98.00
" 2	76	98.00

This patient left the hospital against the advice of Dr. Kennedy, under whose care he was, still retaining many of the symptoms of approaching fever, but has not since returned.

Case 7.—Christopher McM., admitted December 29th, age 16 years. Ill eight days before admission.

	Pulse.	Temperature.
December 29	108	103.00
" 30	100	102.50
" 31	100	102.50
1866—January 1	112	101.50
" 2	104	104.00
" 3	100	103.00
" 4	104	100.50
" 5	84	99.50
" 6	82	98.50
" 7	84	98.50
" 8	60	98.25
" 9	60	98.00
" 10	72	98.00

Convalescent.

This case at first gave symptoms of being a case of typhus, but turned out to be one of febrile catarrh accompanied with parotid inflammation. The great rise in temperature on January 2nd, was immediately followed by the parotid inflammation.

Case 8.—Elizabeth S., admitted December 29th, 1865, age 15. Ill nine days before admission.

	Pulse.	Temperature.
December 29	120	101.50
" 30	104	102.25
" 31	100	102.00
1866—January 1	102	99.50
" 2	90	99.00
" 3	76	98.50
" 4	84	99.00
" 5	96	98.00
" 6	72	98.00

Convalescent.

This was a case of febricula, with some pleurodynia. Case 9.—Teresa W., admitted January 3rd, 1866, age 16. Ill twelve days before admission; densely maculated.

	Pulse.	Respiration.	Temperature.
January 3	140	32	103.25
" 4	132	36	105.00
" 5	144	36	103.50
" 6	112	40	102.00
" 7	126	32	101.80
" 8	96	32	99.00
" 9	112	28	98.00
" 10	96	21	98.00
" 11	108	21	98.00
" 12	96	20	98.00
" 13	120	20	98.00

Convalescent.

This, so far as it goes, may be considered as a typical case of typhus. There was no complication.

Case 10.—Thomas C., admitted January 4th, 1866, age 50. Ill five days before admission.

	Pulse.	Respiration.	Temperature.
January 4	72	22	98.00
" 5	72	24	98.00
" 6	72	20	97.50
" 7	72	20	98.00
" 8	74	20	99.25
" 9	72	24	98.50

Convalescent.

It was at first thought that this would prove a fever case, the state of the tongue and the patient's own account favouring this opinion. The thermometer in this case appears to have indicated that the case would not prove febrile.

Case 11.—Thomas S., admitted January 11th, 1866, age 30. Ill eight days before admission; densely maculated.

	Pulse.	Respiration.	Temperature.
January 11	144	24	104.00
" 12	Imperceptible	30	101.50

The great fall of temperature before death may again be remarked in this case, although not so marked as in Cases 3 and 5.

The thermometers used for taking these observations are made after the directions of Dr. Atkin, and were obtained from Messrs. Yeates and Son of Grafton-street.

(To be continued.)

A curious discovery has just been made at Ferté Bernard, in France. While digging in the Place de la Croix-Buisée, in front of the Church of Cherré, the workmen came upon a number of skeletons buried only a few inches beneath the surface; one of these had a large iron ring passed between the bones of the leg, and which, consequently, must have been riveted on through the flesh, unless, indeed, it was passed there after death, which is scarcely conceivable. Attached to this ring were several links of a heavy chain. Near the spot were the skeletons were found, stood, previous to the year 1200, a gate of the old wall which divided the town of Ferté from the Commune of Cherré. The Place de la Croix-Buisée was outside the wall, and is supposed to have been the place for the execution of criminals. The relics have been sent to the Museum of Mans.

VACCINE LYMPH.—There is at present a great demand for matter, and a liberal price is offered for tubes. Practitioners should neglect no opportunity of laying up a store, as there may be a scarcity by-and-by.

CLINICAL RECORDS ILLUSTRATIVE OF THE DISEASES OF CHILDREN.

By G. STEVENSON SMITH,

RESIDENT MEDICAL OFFICER, ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN.

II.

HYPERTROPHY OF THE LIVER AND JAUNDICE.

ENLARGEMENT of the liver is exceedingly common in children, and may exist for long without giving rise to any serious inconvenience. It most frequently occurs in children of a syphilitic or strumous taint, and according to the experience of Dr. Budd, it is often associated with scrofulous disease of the bones. The manner in which the hypertrophy usually takes place is by the deposit of an albuminoid or fatty matter in the substance of the organ, and a similar deposit is sometimes found in the kidneys and spleen. Unfortunately, medicine can do very little for this affection in the way of cure, and the treatment, which in the majority of cases is merely palliative, must be mainly directed towards improving the constitutional state. Cod-liver oil, the iodide of potassium, the mineral acids, iron, and a judicious diet, are the agents which will be found most serviceable in combating the vitiated state of the system and restraining the morbid exudation from the vessels.

The following case is typical of that form of chronic hypertrophy met with in strumous constitutions, and shows how much the liver may be increased in size, without causing any great disturbance in the circulation or much discomfort to the patient. The boy who was the subject of this disease, was under my constant observation for a period of six months, and it was only for about four weeks before his death that he had any severe suffering. During that time the abdomen was greatly distended, partly with fluid and partly with gas, which in conjunction with some œdema of the lungs, was the cause of a good deal of dyspnoea. He also complained of pain over the right lobe of the liver when pressure was made, or when his position in bed was changed. It is of interest to mention that in this case there was some evidence of a diseased condition of the pelvic bones, a complication which Dr. Budd, in his "Treatise on Diseases of the Liver," mentions as being not uncommon, but which Dr. West has not observed in the cases of which he has preserved a record.

J. R., æt. 4, was admitted to the Children's Hospital on the 13th of March, 1865. He was a pale, emaciated, unhealthy-looking boy, and bore marks of scrofulous disease on the right side of the neck. It was stated that about eighteen months previously an abscess formed in the right lumbar region, and was opened; since which a constant stream of pus has drained away. Ever since that time he had fallen off in health, and for about five months previous to admission his belly had been getting gradually larger. On examining the patient, the skin was found hot, and the pulse was small and rapid; the cervical glands were indurated and slightly enlarged; the muscles of the right leg were firmly contracted, and the limb was drawn up, and ankylosed at the hip joint. Over the ileum, on the same side, there was a sinuous opening, which discharged thick, light yellow pus. A probe passed into it revealed extensive undermining of the skin, but no bone was felt; attempts to move the hip-joint were attended with much pain. The belly was greatly enlarged, and as no satisfactory examination of it could be made, owing to firm spasmodic contraction of the abdominal muscles, whenever the hand was applied, chloroform was administered, and then an enormously enlarged liver was easily diagnosed. The right lobe filled the whole of the right side of the abdominal cavity, its lower margin reaching as low down as the groin; the left lobe extended into the left hypochondriac region, and its lower border could be felt three inches below the ribs; the surface of the organ

felt quite smooth and the position of the transverse fissure could be readily made out with the fingers; there was no tenderness on pressure. The presence of a small quantity of fluid could be detected in the cavity of the peritoneum; with the exception of a few bronchial râles, the chest was healthy; the urine was passed in considerable quantity, and was free from albumen. The iodide of potassium with taraxacum was prescribed, and patient was to have a nutritious diet. On the 17th of March albumen was detected in the urine, and some sanguineo-purulent matter was passed from the bowels. Owing to a continuance of slight bleeding with every stool, and as no piles or other disease of the rectum could be made out, he was put upon small doses of the tinct. of the mur. of iron, which had a beneficial effect. Throughout the months of April, May and June, patient enjoyed very good health, and complained of no pain; his appetite was good, the bowels acted regularly, and the stools were natural. There was no jaundice. In the end of June measles unfortunately broke out in the general wards of the hospital, and patient had a pretty smart attack of them, which pulled him down considerably; he made a good recovery, however, and beyond a slight loss of flesh, the illness had not seriously impaired his health. On the 26th of June a soft swelling was felt over the left lumbar region, and it was tender to the touch; the belly, too, was very much swollen, and numerous blue congested veins were seen meandering on the surface. The increased size of the abdomen was due not to any increase in the size of the liver, for it remained of much the same bulk as when patient was admitted, but to the presence in the cavity of a larger quantity of fluid. He complained of pain if pressure was made over the right lobe of the liver, and murmured if the position of the body was changed; the urine was albuminous, but not diminished in quantity, and of sp. gr. 1015. Fomentations were applied to the belly, and a mixture, containing the ammoniated citrate of iron and the acetate of potash, was prescribed. Patient remained in this condition till the end of August, and on the 30th of that month the report in the case book was as follows:—Patient is much worse, and is getting weaker; the belly is enormously distended, partly from air and partly from fluid; the penis and scrotum, as well as the feet, are very œdematous; the urine is still albuminous, diminished in quantity, and of sp. gr. 1013. Under the microscope numerous epithelial scales are visible. Wine and gin toddy to be given. On September 12th there was increased anasarca of the lower limbs and of the penis and scrotum, and there was great difficulty in breathing; pulse was rapid and very feeble. He lingered till the 13th, and died quietly at two a.m. In my absence from the hospital, an examination of the body was made, thirty-six hours after death, by my friend Dr. Moffat, whose report is as follows:—Body greatly emaciated; abdomen, lower extremities, penis and scrotum, very œdematous; no œdema of upper extremities or face. On opening the chest, about two ounces of clear fluid was found in the pleural cavity; the lungs were both congested and slightly œdematous, but otherwise healthy; the bronchial glands were indurated, but not much enlarged. On opening the abdomen, about a pint and a-half of straw-coloured fluid escaped; the intestines were greatly distended with gas; the liver was of a dirty yellowish colour, the lower margin of the right lobe reaching downwards as far as an inch below the superior spine of the ileum, while the left lobe extended across to the left hypochondrium; the weight of the organ was three pounds one drachm. The spleen was also enlarged and very friable; its weight was four ounces one and a-half drachms. The kidneys were large and pale.

It is of interest to observe in connexion with this case, that there never was any jaundice—a fact which is explained by the nature of the deposit poured out into the interstices of the liver, which being of a soft consistence, and having no tendency to contract, does not much impede the circulation or the flow of bile through the ducts.

From the scantiness of the urine towards the close of the disease, the albuminuria, the anasarca, and the pallor and enlargement of the kidneys, it is clear that in this case a similar infiltration had taken place into the structure of these organs.

JAUNDICE.

We have already remarked that in that kind of hepatic enlargement which has just been described, the occurrence of jaundice is rare. Icterus neonatorum is, however, a very common affection of early life, but as a rule it is happily not very serious in its nature, and is now generally believed to be unconnected with any primary disease of the liver. Cases of jaundice, nevertheless, do occur in children in connexion with serious hepatic disease, or congenital absence of the hepatic or cystic biliary ducts. The following case, which unhappily proved fatal, was evidently attended with a congested state of the liver, but as no post-mortem examination was allowed, the exact condition of the organ could not be ascertained. The intensity of the jaundice was very unusual, and altogether the case is of much interest:—

J. G., æt. 2, was admitted to the Children's Hospital on the 26th of August, 1865; his mother stated that he had never had any of the diseases of childhood, and was in perfect health till within the past four weeks, when he was seized with vomiting, which lasted four days; then his eyes and skin began to get yellow, and the vomiting ceased; he was sleepy and listless, and asked often to be put to bed; he had pain in his belly; was burning hot at night, and was restless and often started through his sleep; he had great thirst, and had frequent calls to pass water, which was very dark in colour. The bowels have been regular, but the stools were noticed to be very white. On admission the colour of the patient's skin was very remarkable; it was of a vivid deep olive green hue, and had a shining appearance; the conjunctivæ were tinged yellowish green; the pulse was quick, skin dry and hot; tongue foul; the liver was felt to be increased in size, and its lower border reached to about an inch above the umbilicus; he did not complain much when pressure was made over it. Fomentations were applied to the liver, and small doses of calomel, to be followed by saline laxatives, were prescribed; the bowels were frequently and freely moved, but the stools were very pale-coloured. On August 28th the child had not improved; the brilliant olive tint of the skin remained, and the urine passed was as dark as coffee, and scanty; it stained linen greenish yellow, and on the addition of nitric acid exhibited that beautiful play of colours from green to red, which is characteristic of the presence of the colouring matter of the bile. The sp. gr. was 1012, and there was no albumen present. On being allowed to stand at rest for a short time, a deposit is thrown down of a yellowish-brown colour; under the microscope numerous rounded and spiculated crystals of the urate of ammonia are seen, along with some epithelial scales, stained yellow; a few crystals of the phosphate of lime were also present. Warm poultices of linseed meal to be applied to the region of the liver, and the fourth of a grain of pulv. podoph. in combination with a few drops of tinct. hyos., was to be given every four hours. August 29th: Patient has rested pretty well during the night, but occasionally cried out as if in pain. The podophyllum has acted on the bowels, and the stools are now tinged with bile; the urine is still of a dark green colour, and has a very strong odour. To have a hot-air bath; the bath did not cause much perspiration, and towards evening patient vomited everything he swallowed; a few drops of solution of the muriate of morphia with sulphuric ether were administered, and had the effect of quieting the stomach; the citrate of potash was ordered as a drink, and enemata were likewise given. The child then began to sink very rapidly, and notwithstanding the administration of stimulants, he died at one p.m. of the 30th. The parents positively refused any examination of the body.

The sudden occurrence of the jaundice in this child,

who had been previously quite healthy, along with the pain in the hepatic region and the vomiting, would lead us to infer that the cause of the disease in this case was some impediment to the flow of bile into the duodenum. But what the nature of the impediment was it is not possible to say with any certainty, seeing that no opportunity was afforded for an examination of the body; and it is much to be regretted that the real nature of the enlargement of the liver diagnosed during life, could not be ascertained.

ON

AMPUTATION BELOW THE KNEE, AT THE PLACE OF ELECTION.

By GLASGOTT R. SYMES, L.R.C.S., L.K.Q.C.P.,
ONE OF THE SURGEONS OF STEEVENS' HOSPITAL, DUBLIN.

OF capital amputations of the lower limb this is by far the most frequent. It is had recourse to in disease and injury of the foot or leg, where if in the upper extremity efforts would be made to spare every inch; thus it is practised for cases which would probably be suited for amputation at the ankle-joint, and for causes affecting the limb at any point up to the situation of our incisions. Except by a few it is regarded in a poor person as preferable to amputation through the middle or lower thirds, although there is no doubt but that the latter is well adapted for a person of easy circumstances, who can afford to go to the expense of a well made artificial limb, and who can spare the stump as occasion may require.

The point to which I wish to draw particular attention is the method of the operation, whether by flaps or by circular incision. I admit that there is now a growing tendency to the contrary, but still there is a hankering after the old operation, and many will be found who insist that the leg should be removed at the seat of election, where feasible, by flap amputation. Without taking into consideration the reasons against such a mode of procedure, I have myself frequently, following the example of others, amputated in this way, where, if I had taken the trouble of casting the subject over in my mind, I would have acted very differently, and have been saved much annoyance.

The first question that presents itself in an inquiry of this nature is, What do we gain by a flap amputation? The object aimed at, as far as I can see, is twofold—rapidity of execution and superiority of the resultant stump.

There is a certain amount of *éclat* attending a flap amputation, which is not consequent on the performance of the circular. A dashing surgeon can show off before a class of students in such a case; he has all the soft parts divided in almost as few seconds by two clean cuts of his catlin, whereas in the circular method several incisions and some dissection would be required; but here there is no rapidity of execution necessary; and since the introduction of anaesthetics, in the absence of sensibility, it is not called for particularly, except through fear of hæmorrhage. Although this latter is a subject for consideration in amputations high up in the thigh, yet below the knee it is reduced to a minimum. When flap operations came into favour first they were thought to be peculiarly adapted to the upper part of the limb, for this very reason; but now so much has the fashion changed, and so little do they fear hæmorrhage, that the majority of surgeons adopt Mr. Teale's admirable operation by rectangular flaps, which is notoriously tedious compared with the old circular; but then it has points to recommend it in that situation which do not come under consideration at the "place of election."

Now, as regards the second object aimed at—superiority of the stump—that form of stump is the best which will bear pressure. Liston taught that muscular flaps made the best stump, then came a reaction in favour of skin flaps. Mr. Teale's success proves that though the muscle covering the end of a bone is absorbed, yet it leaves a tissue which is the best calculated to serve the purpose,

but there is no need here to enter the lists in a discussion on this point. When the intention is to use the stump as usual in the kneeling posture on an artificial limb there is not the necessity for the bones to be so well covered with a pad, as there will be no pressure exerted in this direction, the whole weight falling on the tuberosity of the tibia and front of the knee-joint. It is true, indeed, that orthopaxists now manufacture artificial limbs which retain the movements of the knee, for the use of persons whose legs have been amputated close to the joint, but these are expensive, not within the reach of the majority, and we find that most prefer the old-fashioned splint leg. In cases which are afterwards intended for using such limbs we generally find that we can leave a longer stump, and that we are not bound to operate at the seat of "election."

Having now disposed of the arguments which are in favour of amputation by flaps in this situation, let us consider the positive objections to it, and these we will find to be grave. It is an axiom in surgery which requires no proof, and which is sufficiently evident to the common sense of anyone, that the smaller an exposed raw surface is the better, the less time will it take to heal, the less will be the danger, and the less will be the discharge from it. Now the surface exposed by a circular is far less than that exposed by a flap amputation; the former is, therefore, to be preferred. Those cases in which union by the first intention is said to follow a flap, and indeed also a circular operation, are so few as to be almost mythical.

No matter how gradually the posterior flap may be sloped off, we always find that there is a redundancy of muscle, the skin retracting more, and when we proceed to dress the stump and approximate the flaps, we often experience a difficulty in stowing away the muscle, owing to the comparative shortness of the skin, and frequently in a muscular subject we are obliged to cut a portion away. This not only is objectionable for its tediousness, but the tension which the skin is called on to sustain is highly injurious, giving rise to constitutional and local irritation.

In my mind the most objectionable point of the whole operation is the "slicing" of the vessels which takes place in a flap amputation. Anyone who is familiar with the anatomy of this region will recollect the large vessels which are found in such numbers entering the head of the gastrocnemius muscle. These are cut obliquely across, and it is very difficult to apply a ligature properly; in addition to this it is often not easy to find them, as vessels of this size are not inclined to spout unless cut transversely. Before now I have seen the knife meet the artery a second time, so that a piece was actually cut out and the bleeding came from both portions. Besides these arteries, the upper part of the calf is very vascular in the adult labouring man; and when the limb has been removed in this situation for an accident, the posterior flap is very prone to "ooze" for some time after. In my own practice I have lost a case, as detailed below, in which I think the fatal result was to be attributed to this cause. It is pretty well established now that puerperal fever and surgical fever are the same, arising from the same causes and influenced by the same circumstances. It is an acknowledged fact that those cases are more prone to puerperal fever, and bear it worse, in which hæmorrhage has followed parturition, so in the same way operation cases, which are followed by hæmorrhage, are more likely to be attacked with surgical fever than others where the vessels can be seen for the purpose of being properly secured; besides, as the bleeding here frequently comes from the capillaries, the surgeon is obliged to open up the stump it may be the next day, and often has to apply styptics to the raw surface, a remedy of all others to be avoided. This is obviated by the circular amputation, or at least the chance of capillary hæmorrhage is reduced to a minimum.

Under any circumstances it is very difficult to apply a ligature on the posterior tibial artery in this situation. It will be remembered that the peroneal, anterior and posterior tibial, may all be found just at their commencement.

The vessel appears to be more firm and resisting here than lower down, so much so that while tying the second knot the first may slip. If this occur where the artery is cut transversely, how much more likely is it to occur where the vessel is cut in a slanting direction, as it is in very many cases? it even frequently is pierced by the knife. Hæmorrhage in a case of this nature may occur to an alarming extent. Mr. Skey's method of taking the posterior flap from only a portion of the calf and dividing the rest transversely, as in a circular amputation, is to be commended as far as the condition of the main artery is concerned, but otherwise it is open to all the objections which I have been endeavouring to lay down.

On the whole, I am obliged to confess that the flap amputation at the "place of election" is a bad operation and it is to be observed that almost all hospital surgeons who have had experience abuse it; yet many persons will be found, urged as it were by a strange infatuation, to perform an operation which is not called for, and which is open to so many and serious objections.

The circular method, on the contrary, fulfils all our requirements, and reduces to the minimum the chances against and dangers of a capital operation.

Mr. Syme's method, too, is to be commended; he makes skin flaps and divides the muscles as in a circular amputation.

The following are a few cases to illustrate the foregoing remarks; if I had kept notes of all I should have been able to have furnished more:—

Case 1.—W., æt. 13, admitted to Steevens' Hospital on disease of the ankle-joint, highly strumous. After some weeks the leg was removed by posterior flap at the place of election. Thirty-six hours afterwards I was called on to arrest arterial hæmorrhage, which had occurred suddenly, and to an alarming extent; this was accomplished by means of the pressure of a tourniquet; the case ultimately did well.

Case 2.—L., aged about 26, had his foot injured at Inchicore; the limb was removed in Steevens' Hospital by flap amputation below the knee; hæmorrhage occurred forty-eight hours after, the flap was opened down, some ligatures removed and new ones applied; flap was readjusted, hæmorrhage came on again, the flap had to be opened again and left so to heal and contract by granulations; the case ultimately did well. Although the wound cicatrized completely a piece of lint, which had been used as a pledget on a vessel, was enclosed in the stump, and was not discharged for near four months after.

Case 3.—T. F., aged 8, had both legs fractured by machinery; one was so bad as to require removal in Steevens' Hospital. I amputated at the seat of election with posterior flap. On the second day I was obliged to open up the stump, as owing to the inflammation that followed from the contusion of the muscles at the time of the accident the parts were in a state of great tension. I need not say that the wound took a longer time to contract than if the circular amputation had been performed.

Case 4.—A man, aged 27, had his leg removed at the knee-joint for disease in Steevens' Hospital. A large flap from the upper part of the calf was made use of to cover the stump; hæmorrhage came on shortly after the operation and continued for two days; the stump was opened up more than once; the case, however, ultimately did well.

Case 5.—A man, aged 25, had his foot injured by machinery. I amputated his leg below the knee by flap operation in Steevens' Hospital; he was a very powerful muscular fellow; the wound commenced to "ooze" very shortly after; although it was opened and styptics applied, the hæmorrhage continued; finally it was left open and the oozing still continued; he died of surgical fever on the eighth day.

Case 6.—A surgeon of my acquaintance also operated this way lately on a man, hæmorrhage set in six hours after, the wound was kept open and styptics applied, but the patient died of surgical fever.

HOSPITAL REPORTS.

LONDON SURGICAL HOME.

OVARIOTOMY has now become generally recognised as a justifiable operation. It has been performed in nearly all the Metropolitan London Hospitals, in many English provincial, in Scotland, and lately, with success, by Mr. Butcher, in Ireland. Germany and Belgium have long recognised this operation as one imperatively called for in certain cases, and have contributed their share to the statistics of success. France, also, led by M Nélaton, who did not consider himself too old to learn at a time when most men would retire, and who came to England expressly to gain personal knowledge of the operation and after-treatment from a London surgeon, has worked at the subject, and if the surgeons of that country have not succeeded so well as others, it has not been through want of operative skill on their part, but rather to radical defects in the sanitary arrangements of their hospitals, and more especially to a different method of after-treatment. Quite lately we have seen a careful translation into Italian of Mr. Baker Brown's work on "Ovarian Dropsy" by Dr. Peruzzi of Seriegaglia, who, when in England, was a constant student of Mr. Brown's practice, and has, in his own country, performed this operation on two occasions, the details of which he gives in an appendix to his translation.

There is no doubt that ovariectomy is the operation of the day. Every surgeon who gets a successful case publishes it, often with a detail of minutiae amusing to those who have seen scores of such cases. The slightest variation in the treatment of the pedicle, or the least modification in the after-treatment, is said to be the cause of success, and there is reason to fear that this over-confidence in matters of but slight importance will carry men away from the grand question which alone ensures a fair chance of success. Although we ourselves believe that Mr. Baker Brown's method of treating the pedicle by division with the actual cautery is the best, we willingly acknowledge the great success of Mr. Spencer Wells, who uses the clamp, and simply compresses the pedicle, afterwards allowing it to return; or again, Dr. Tyler Smith's plan of tying the pedicle with twine, cutting the ends off short, and returning the whole at once into the abdominal cavity. These matters are, after all, questions for each surgeon to decide for himself. The real point is, can he distinguish when ovariectomy is called for; whether, indeed, he has an ovarian cyst to treat, or some other tumour of the omentum, uterus, or pelvis?

It is not too much to say that no surgeon can always diagnose what is the tumour which he has to deal with. The faithful records of all our ovariectomists but too truly confirm us in our statement, and we believe that we shall best serve the cause of ovariectomy by relating a few such cases lately under the care of Mr. Baker Brown, who has now worked more than thirty years at ovarian disease. Increased experience has taught this gentleman to say that he cannot in many instances tell what is the nature of the disease until he has made an exploratory incision, and to those assembled around him on operation day at the London Surgical Home, his preliminary observation is always to that effect. If this is the case with one of the oldest ovariectomists, it behoves those who publish one or two successful cases with a great flourish of trumpets rather to be humble, lest, with all the success which their new knife, trocar, needle, or clamp has given them, they some day cut into an abdomen for an "ovarian tumour" to find a fæcus or some other complication which they have not anticipated.

COLLOID TUMOUR OF OVARIES, UTERUS, AND RECTUM, WITH ASCITES: ATTEMPTED EXTIRPATION: DEATH ON THE EIGHTH DAY.

(From notes by Dr. BOTTLE, late House-Surgeon.)

Case 1.—Elizabeth S., æt. 28 years, admitted September 29, 1865.

History.—Married ten years, has never been pregnant. She enjoyed very good health up to five years ago, when she began to feel generally out of sorts; but it was not for a year after this that she noticed any swelling of the abdomen. Three years and a half ago she was tapped, and since then the operation has been repeated twenty-three times; on the last occasion forty-nine pints of fluid were evacuated. The catamenia, which suddenly ceased three years ago, had up to that time been quite regular.

On examination, the abdomen is large, tense, and globular; the parietes very thin. Percussion note is resonant in the flanks and dull in the umbilical region. Fluctuation is very distinct in every direction.

Operation, October 5th.—It having been agreed on consultation that an incision was the only way of clearing up the difficulties of diagnosis, Mr. Brown operated. On exposing and puncturing the peritoneum, a large quantity of ascitic fluid escaped. The incision being enlarged, a large cauliflower growth was exposed, and found to be attached to the right ovary and uterus, with extensive ramifications inseparably adherent to the pelvic fascia. A broad band of adhesion to the omentum was divided by the actual cautery, and a few loose small cysts removed by the same means. As it was impossible to remove the mass, the wound was closed up in the usual way by silver sutures. She rallied badly, and peritonitis soon supervened. On the 10th the sutures burst open at the lower end of the wound, a large quantity of fluid gushed out, and immediately the patient seemed to revive. This was a change, however, only of short duration. She gradually sank, and, October 12, died at twenty minutes past twelve a.m.

Sectio-cedaveris sixteen hours after death.—About two or three pints of yellowish brown puriform fluid in the cavity of the peritoneum; the intestines firmly matted together with recent lymph. The mass was attempted to be removed from the cavity with the pelvic organs, but it was extremely friable, breaking on the slightest touch, and intimately adherent to the fasciæ. Uterus, ovaries, and rectum were also found incorporated with the tumour. The tumour consisted of small lobulated viliform masses, the pedicle of each lobe consisting of a large vein.

ALMOST SOLID TUMOUR, IMPLICATING UTERUS AND RIGHT OVARY, AND FILLING UP THE CAVITY OF THE PELVIS: PARTIAL EXTIRPATION: DEATH.

(From notes by Dr. BOTTLE, late House-Surgeon.)

Case 2.—Mary C. M., æt. 13 years, admitted October 5, 1865.

History.—Has never menstruated; has noticed her abdomen to be enlarged for the last two years, but considered herself pretty well until a month ago, when she began to suffer much from pain in the back with a "throbbing in the belly." The tumour has increased very rapidly lately, the proportion being an inch increase in circumference every week. The tumour presses on the bowel and causes great difficulty in defecation.

On examination, the abdomen is large and tense, measures thirty-six inches and a half at the umbilicus. Stretching across the umbilical region is a hard subcutaneous mass, over which the parietes are freely movable; another smaller but similar mass can be detected in the right iliac fossa; there is superficial fluctuation as of ascitic fluid. The child has a hectic appearance, rapid sharp pulse, hot skin, and flushed face. The vulva is very œdematous, and evidence of general anasarca. Relief is imperatively called for.

Operation, October 19, 1865.—Mr. Brown having made an incision seven or eight inches in length, evacuated a considerable quantity of ascitic fluid. A large and very solid tumour attached to the left ovary was then exposed and removed without much difficulty, there being only a few easily broken-down adhesions.

The pedicle, broad and thick, having been divided by the actual cautery, the wound was closed, and the patient

removed to bed. The patient recovered well from the chloroform; but on endeavouring to feed her by enemata, it was found that nothing was retained in the rectum. Simple laxative enemata were also returned. She was continually vomiting; the abdomen became painful and very tympanitic, especially at epigastrium, and she gradually succumbed, and died rather suddenly on the 22nd at fifteen minutes past six p.m.

Section cadaveris fifteen hours after death.—Body much emaciated; rigor mortis very freely developed; some slight attempt at union in the wound; both large and small intestines distended with flatus.

About the region of the pedicle there has been a little lymph thrown out, but none around the intestines, which are not even injected. There is about half a pint of darkish-brown fluid in the peritoneal cavity.

The mesenteric and lumbar glands are very much enlarged, and when cut across have a white cheesy aspect, and exude a milky fluid.

Kidneys large, capsules readily separate; no distinct margin between the cortical and medullary portion; substance very rough.

Filling each half of the true pelvis is a firm white tumour adherent to the pelvic fascia all around, and also to the rectum.

This mass was removed with difficulty, when it was found to have so compressed the rectum as to entirely occlude its cavity. This accounted for the rectal symptoms before death. The tumours varied in consistence in different parts, being generally fibroid in feel and appearance. At other parts they resembled the glands as just described. It was found also that this was only part of the removed stem, as the fundus uteri had been removed with the pedicle; the os and cervix uteri were healthy.

Remarks.—Mr. Brown, when operating, remarked that this was the youngest patient on whom he had yet attempted extirpation of an ovarian tumour. The operation was performed, as the child was evidently dying from the pressure of the tumour, and as removal was the only means which offered a chance of recovery.

DROPSY OF AN OVULE ESCAPED INTO THE PERITONEAL CAVITY EXTENSIVELY ATTACHED TO THE OMENTUM: EXTIRPATION: RECOVERY.

(From notes by Dr. OCTAVIUS GROSVENOR, House-Surgeon.)

Case 3.—Mary C., æt. 48 years, admitted December 19, 1865, was sent to Mr. Brown by Dr. Joseph Bullar of Southampton.

History.—Has had eleven children, the youngest of whom is five years of age. All her labours have been good, with the exception of the ninth, when she was in labour for a week, when she was delivered by forceps under chloroform. Three years ago she first complained of pain in the right side, which recurred in increased severity at intervals of six months. Six months since, after severe pain, she first noticed her abdomen has rapidly increased in size until now, and is so inconveniently large that she seeks relief. When she first felt the pain three years ago, she was irregular in her menstruation, being sometimes three or four months between each interval.

On examination, the abdomen is large and spherical, measuring on a line with the umbilicus forty-seven inches in circumference. There is a tumour very movable, and which can be readily "tossed" about. There is also evidently considerable ascites.

Operation, December 28th.—Mr. Brown (having conferred with his colleagues) made the usual incision, and having released a large quantity of ascitic fluid (over four quarts), exposed a tumour of an irregular oval form, having all the appearance of an ovarian tumour which had been inflamed on its surface. On being tapped, twelve pints of dark, muddy, and mucilaginous fluid were withdrawn. The tumour was attached to the omentum by three separate broad adhesions (principally on the right side), which were divided by the actual cautery and

clamp. One large bloodvessel of the omentum, which which bled freely, was tied.

Both ovaries and uterus were healthy, and quite free from any adhesion to the tumour.

January 15th: Up to this date the patient is perfectly well, and has recovered without a bad symptom since the operation.

Remarks.—Dr. Barratt, Physician to the Home, carefully examined this tumour, and gives the following opinion:—

"The mass consists of five hundred chief cysts, holding (with one exception, where the contents are more solid) five or six ounces ofropy mucus and soft puriform fluid, really albuminous, with fatty matter breaking down and softening.

"The cyst wall presents all varieties of epithelial cells, the flattened pavement, like the spheroidal and the columnar covering large villous growths, well shown by Dr. Fox in *Medico-Chirurgical Transactions*, vol. xlvii., plate 9, figure 16.

"That it has an ovular origin and has become sessile, *licked up (sic)* by omentum and then developed, is my present conviction."

(This tumour was exhibited at the Pathological Society on January 16th.)

PROCEEDINGS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, DEC. 5, 1865.

Dr. PEACOCK, President.

THE PRESIDENT showed, in conjunction with Dr. HICKS, a specimen of

ULCER OF THE ŒSOPHAGUS

from a person of intemperate habits, who had long complained of difficulty of swallowing, referred to the lower part of the neck. On post-mortem examination, the calibre of the œsophagus was found much narrowed by the cicatrization of a small ulcer, which was nearly healed. There was no enlargement of the glands in the neighbourhood. The origin of the disease was connected with a violent fit of coughing, in which he was said to have brought up some blood.

Mr. CANTON showed a specimen in which there was a Clubbed state of the Fingers of the Right Hand only, with disease (subclavian aneurism) of the right side; the arteries on the other side being healthy. The artery in this case was tied on the distal side; but the disease progressed, and the patient died in a fortnight of pleuropneumonia. The clubbed fingers appeared thickened, but with no adventitious deposit, and no enlargement of the phalanges, as has been thought to be the case. Another view of the pathology of this disease refers it to obstruction in the capillary circulation, and consequent enlargement of the veins. This was not verified in this case, in consequence of the part not having been injected.

Dr. DICKINSON showed three cases of

DISEASED CORONARY ARTERIES,

in which the patients had died of angina pectoris. One patient was a middle-aged man, a patient of Dr. Pudfield. All the other organs were natural. The aortic valves were very slightly diseased. The heart was enlarged. The root of the aorta was atheromatous, and the atheroma had encroached on the origins of the coronary arteries, so that one was quite impervious; otherwise the coronary arteries were tolerably healthy. The other cases were extremely similar to the above. In one of the latter, the patient was out walking at the time of death. In all these cases, one of the coronary arteries was obliterated at its origin, the other nearly impervious. In all of them also, the muscular substance was hypertrophied, but with very slight fatty degeneration. Dr. Dickinson called attention to the close relation of the coronary arteries with the nervous

tissues of the heart, and to the occurrence in all these cases of cardiac neuralgic symptoms, while the nutrition of the heart was unimpaired. Hence he inferred that the muscular tissue must be nourished from some other source.

Mr. ERNEST HART exhibited a specimen of CANCER SPRINGING FROM THE DURA MATER AND PROJECTING INTO THE ORBIT.

The patient was a child. The eyeball was protruding, but the sight was perfect. There was a smaller projection on the temple. After death, extensive disease and thickening of the dura mater were found, with spots of cancer strewn about on the membrane, and thickening of the periosteum of the bones of the orbit. A point of interest in this case which he saw in consultation with Mr. J. B. Walker of Bayswater, was the perfect vision coincident with great lengthening of the optic nerve. Mr. Hart mentioned another case in which the eyeball was affected with cancer, and where the power of sight was immediately lost. In this case, which he saw in consultation with Mr. Fyfe of Brompton, the cancer had originated in the optic nerve, and there was a great predominance of large ganglionic cells. In the case where sight was long preserved, the cancer had originated in a fibrous membrane; the dura mater and much fibrous tissue were found in it, with small nuclei.

Dr. CAYLEY showed a specimen of Arrested Development in the Upper Extremity.

Dr. CAYLEY also brought forward a case of Abscess of the Cerebellum, with Caries of the Temporal Bone. The man died at the age of forty, having had disease of the bones of the ear from the age of five years.

Mr. T. SMITH showed a Foot in which four Cuneiform Bones were found, the internal cuneiform bone being divided into two; the scaphoid having four articular surfaces, and the great toe two. Mr. Smith had found several feet in which the separation of the internal cuneiform bone was not complete, but was well-marked.

Mr. SMITH also showed a large Congenital Fatty Tumour, removed from a young female child, situated in the buttock, and lapping round the femur, presenting on both sides of the adductor magnus. It was firmly connected to the pelvis. The tumour was successfully removed.

Dr. GIBB exhibited a

FIBRINOUS CAST OF THE TRACHEA AND BRONCHI

of a child five years old, admitted into Westminster Hospital, who had had croup for three days previous, and upon whom tracheotomy was performed the night of admission. The child went on well up to the third day, when the tube of the canula became blocked up by portions of loose fibrin, which nearly suffocated him. Dr. Hawker, the house-physician, however, removed the canula, and extracted a complete fibrinous cast of the trachea and larger bronchial tubes. The child at once rallied, but unfortunately died from pneumonia on the ninth day after the operation.

Dr. GIBB also showed a

TAPEWORM EXPELLED WITH ITS HEAD,

from an hospital patient treated with the oil of male fern. The practice Dr. Gibb is in the habit of pursuing with general success is to administer a dose of castor-oil at night, followed by the fern oil at seven o'clock the next morning, and another dose of castor-oil three or four hours afterwards, the patient meanwhile fasting. The passage of the head of the worm is, of course, the great thing desired in the treatment, when the cure is considered complete.

Mr. CURLING exhibited a specimen of

COLLOID CANCER OF THE LOWER PART OF THE COLON, in which colotomy had been performed for the relief of symptoms of obstruction of the intestine, with temporary success. The patient was a lady of advanced age, who had suffered from a tumour in the pelvis unconnected with the uterus. She had had great pain in the part, followed

by total obstruction. The patient survived the operation for eleven days. There had been no bloody or mucous discharge. The gut was diseased for about three inches, and there was colloid cancer of one ovary, but not pressing on the gut. Mr. Curling dwelt on the relief of pain which followed the operation, and the slight prolongation of life which followed it.

Mr. SULLY thought that there was too great fear of opening the colon in such cases as this—an operation which he believed to be urgently called for.

Mr. CURLING also showed a drawing from a child one month old, in whom the testicle was found in the perineum at the time of birth; the scrotum being developed, but empty. He likewise produced, by way of contrast, a photograph from an adult patient, in whom the testicle was in the perineum, but the scrotum on that side was quite empty. Mr. Curling had performed an operation for the replacement of the testicle in its proper place. He succeeded in removing it from the perineum, but could only succeed in transferring it to the neighbourhood of the ring. He referred the difficulty in this case to the action of the cremaster rot being balanced by the gubernaculum, as is usually the case.

Mr. GASCOYNE showed a Fatty Tumour of large size, weighing 5 lbs. 6 oz., removed by Mr. Lane from the scrotum of a patient 52 years of age. The tumour seemed to be connected with the cord, which itself was healthy. (This tumour was referred to Dr. Hicks and Mr. Barwell for a report.)

Dr. OGLE showed a Tumour of a Cancerous Nature from the Mesenteric Gland in an adult. There had been no vomiting or other symptom. Many cysts had been found in the tumour.

Dr. OGLE also showed a False Membrane lining the Arachnoid Cavity in a patient suffering from dementia, and several masses of calcareous matter found in the brain, and apparently the result of the degeneration of tubercle.

Dr. FAGGE exhibited a specimen of Fibro-cystic Tumour of the Uterus, which had existed for at least twenty years before the death of the patient. There had been no uterine symptoms known. The patient had had one miscarriage, but no children. There was a slight suspicion of extra-uterine pregnancy, but the idea of ovarian tumour was negatived. The cavity of the uterus was dilated, and contained a small polypus. The right ovary was not found. The tumour was surrounded on all sides by the fibres of the uterus, and a good deal of calcareous matter was present in the tissue of the tumour.

Mr. LEGGATT showed a case of Dissecting Aneurism of the Aorta with rupture into the pericardium, situated about half an inch above the valves. There was some loss of power, but no complete paralysis.

Dr. BROADBENT showed a specimen of Aneurism of the Middle Cerebral Artery which had burst into the brain.

Mr. GAY introduced to the Society a living specimen of Glandular Disease, forming a large collar round the neck and a large mass in the axilla on both sides. The disease had begun about a year ago with enlargement, followed by inflammation and subsequent ulceration of the affected gland. The disease spreads rather externally than internally, like cancer; but it does not possess the microscopic elements of cancer or of tubercle. The general health is good and the secretions are healthy.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JANUARY 3, 1866.

Dr. BARNES, President.

THE following gentlemen were elected fellows:—Messrs. R. J. Cave, Birmingham; John Deans, Cranbrook; F. H. Gervis, Adelaide-road; W. K. Giddings, Calverley, Yorkshire; T. Langston, Broadway, Westminster; W. T. Molloy, Balmoral, Victoria; Jabez Thomas, Swansea; Drs. W. C. Lucey, Bermondsey; J. E. Neild, Melbourne,

Victoria: Mark Tanner, St. George's-square, Pinlico; H. J. Yeld, Sunderland,

Dr. SWAYNE, of Clifton, read a case of Double Monstrosity.

Mr. W. OWEN read a case of Mechanical Obstruction to the Growth of a Fœtus.

Dr. CORY exhibited an Ovum Forceps.

Dr. MURRAY showed two large Kidneys, weighing seven ounces four drachms, and six ounces three drachms and a-half, which had been removed from a still-born fœtus, otherwise normally made.

Dr. EASTLAKE read

BRIEF NOTES ON SOME UTERINE THERAPEUTICS.

The author first drew attention to the action of the resin of podophyllum on the uterus. He found an emmenagogue effect produced in several cases where it had been prescribed for constipation. He referred secondly to the beneficial use of the spiritus pyroxylicus rectificatus in cases of obstinate vomiting; and lastly spoke of "iodoform" as a sedative in cases of cancer especially attacking the uterus. The drug was discovered by Scrullus in 1824, and is produced by the action of iodine and alkalies or alkaline carbonates on wood spirit, alcohol, or ether. Dr. Eastlake has used it with much success locally, by means of medicated pessaries, the effect produced being a marked diminution of pain and discomfort.

Dr. GREENHALGH stated that eighteen months ago Dr. Eastlake called his attention to iodoform, suggesting its use as an anæsthetic and alterative, especially in cases of cancer. He (Dr. Greenhalgh) first gave it in quarter-grain doses, but soon found that it might be administered in pills of three to five grains thrice daily. He had prescribed the drug in carcinoma, epithelioma of the uterus, rheumatic gout, neuralgia, and other painful diseases, in most of which it had been followed by good results. In some cases, but slight effects appeared to result from its use, whereas, in a limited number, when given at once in full doses, sickness was occasioned. He considered it had the advantage of never producing that malaise so frequently attendant upon the use of opium, and regarded the drug as a valuable addition to our present stock of medicaments.

Mr. GASKOIN remarked that for many years he had been aware of the employment of iodoform as a disinfectant in many parts of the Continent; but that he had been unsuccessful in obtaining much information concerning it. The objection to its general use was its expense as compared with other disinfectants.

Dr. WOODMAN said that a small quantity of iodoform is produced when the compound tincture of iodine is prescribed with liquor potassæ—a favourite combination with many country practitioners, and considered by many to be more efficacious in the treatment of bronchoceles than iodine alone.

Dr. HALL DAVIS communicated the report of a case of
FIBROID TUMOUR OF THE UTERUS WITH EARLY PREGNANCY.

At first there had been retroversion of the womb and retention of urine. The latter was relieved by the catheter, the patient being placed in the kneeling posture; the former by the caoutchouc ball air-pessary. Nine days later (Sept. 29th) the patient came into hospital, presenting a considerable-sized solid enlargement of the abdomen, extending as high as the last rib. She was feverish, reduced in flesh, frequently vomiting; subsequently dysuria and renal pain appeared; later scanty urine and drowsiness, and also sloughing of the cornea, &c. She died on the 18th of October, after on the day previous discharging a putrid fœtus of about four months' growth. The morbid specimen, which was exhibited to the Society, showed a large fibroid tumour, of kidney shape, attached to the fundus of the uterus; also others much smaller growing from the cervix, in the substance, others bulging on the surface of the body of the uterus. The kidneys

contained purulent deposits; the ureters were dilated. Dr. Davis concluded that this patient died from pyæmia, and that had an early discharge of the decomposed fœtus been brought about, the patient's life might have been saved. It first became apparent at the autopsy that the largest fibroid might have been easily removed; others, however, would have remained for subsequent development had the patient survived extirpation of the tumour.

Dr. ROUTH said the case was important, viewed in the aspect of what should be done in such cases—*i. e.*, when we had abdominal tumours and pregnancy coexistent. The post-mortem examination revealed a large fibroid extra-uterine with small pedicle; precisely the case most favourable for gastrotony. Should this patient have been operated upon before labour had taken place, or should labour have been prematurely induced first? He thought the latter: First, because it commonly happened that when abdominal tumours, whether ovarian, but especially if fibroid, were operated upon before labour, a miscarriage or premature delivery occurred; occasionally death. Secondly, if premature labour was induced, then not only was diagnosis made more easy as to the exact nature and bearings of such a tumour, but the impetus given to its rapid growth by pregnancy was removed.

ANNUAL MEETING.

The report of the auditors of the accounts of the treasurer for the year ending Dec. 31st, 1865, was read, from which it appeared that the balance in the hands of the treasurer is £234 18s. 8d., and the amount invested in Consols is £881 10s., representing in Three per Cent. Annuities £955 15s. 1d.

Dr. TYLER SMITH moved the adoption of the report, and warmly congratulated the Society on its present very flourishing condition.

Mr. MITCHELL seconded the resolution, which was carried unanimously.

The report of the hon. librarian (Dr. Meadows) was then read. After detailing the general condition of the library, the report recommended that attempts should be made to establish in connexion with the library a museum of pathological anatomy, by preserving such specimens as, having been exhibited to the Society, were afterwards presented for that purpose. The entire cost of the library for the year was £61 3s. 5d. The number of works presented was upwards of sixty, making a total of nearly 900 volumes, a classified catalogue of which is about to be published in the forthcoming volume of "Transactions."

Dr. GREENHALGH moved that the report should be received and adopted. He warmly commended the suggestion of the establishment of a museum, and offered a donation of five guineas towards a separate Museum Fund, and a similar sum towards a Library Fund.

Dr. WYNN WILLIAMS seconded the resolution, which was unanimously carried.

Dr. MARTYN proposed, and Dr. CORY seconded, "That the best thanks of the Society be and are hereby given to the president and officers of the Society for their services during the past year, and that the special thanks be given to Dr. Braxton Hicks, the retiring hon. secretary, for the very efficient way in which he has discharged his duties."

The President (Dr. Barnes) and Dr. Braxton Hicks respectively returned thanks.

The report of the scrutineers was read, and the following gentlemen were elected officers of the Society for the year 1866:—Hon. President: Sir Charles Locock, Bart., M.D. President: Robert Barnes, M.D. Vice-Presidents: Dr. Gream, Dr. Greenhalgh, Mr. Haden, Dr. Hicks, Dr. Hall (Brighton), Dr. Wilson (Glasgow). Treasurer: Dr. Grailly Hewitt. Hon. Secretaries: Dr. Meadows, Dr. Murray. Hon. Librarian: Mr. James Reeves Traer. Other Members of Council: Dr. Aveling (Sheffield), Mr. Thomas Bryant, Dr. Earle (Birmingham), Dr. Eastlake, Dr. Gervis, Dr. Leishman (Glasgow), Mr. Mitchell, Mr. Newton, Dr. Oldham, Mr. Oldham (Brighton).

ton), Dr. Timothy Pollock, Dr. Priestley, Mr. Ray, Dr. Richards, Dr. Skinner (Liverpool), Dr. Tyler Smith, Mr. Wm. Squire, Mr. Symonds (Oxford).

The PRESIDENT then delivered the

ANNUAL ADDRESS.

After advertising to the continued prosperity of the Society, and the place which its "Transactions" occupied in obstetric literature, he observed that hitherto the annual surplus had been invested in the Funds; but now, the position of the Society being secure, it was thought better to put out what money could be spared at scientific interest. There was nothing so fruitful as knowledge spread abroad. It gathered increase at an infinitely quicker rate than did capital in the Three per Cents. He hoped therefore that more money might in future be spent upon the library and in forming a museum. The sale of "Transactions," indeed, during the past year had more than covered the rent and cost of maintenance of the library. The President then passed on to recount the losses the Society had sustained amongst its Fellows. It had never before fallen to the lot of its President to record so long a series of losses by death. He gave sketches of the lives of the late Dr. F. W. Mackenzie, Dr. Edwin E. Day, Mr. Decimus Nelson Frampton, Mr. Arthur Octavius Arden, Dr. Thomas Herbert Barker, Mr. Henry Merton Gould, Mr. Charles Saunders, Dr. William Bloxam, and Dr. Charles G. Ritchie. He dwelt more especially upon the personal and professional merits of Dr. Barker and Dr. Bloxam. Turning from the task of commemorating the lives of lost companions in labour, the President directed attention to the work before the Society. He hoped the proposed *conversazione* and exhibition of instruments would prove interesting and instructive. By bringing together the instruments that had been used in different ages and in different countries for the purpose of overcoming those obstetric difficulties which are met with in all ages and in all countries, we should be able to read by those tangible symbols the most important chapter in the history of obstetrics; we should be able to enter into the thoughts of our predecessors and contemporaries by studying the visible expressions of their minds labouring in the cause of our common science; and do something towards identifying and preserving the original forms of instruments as they were designed and used by their inventors. An instrument was not less the offspring of a man's mind than was a book. Libraries preserved books in their original form. But the security for preserving an instrument so that it should, even for a brief time, tell truly the working of the mind that produced it, and continue to answer in the hands of others the purpose for which it was designed, was very small. Instruments were made under instructions that were more or less faithfully observed; and there was a constant tendency to depart from the original forms under the hands of mechanics and the ideas of subsequent practitioners. Considerations such as these suggested to the President the project of instituting this exhibition. It had met with the cordial approval of the Council; and the College of Physicians had, in the most liberal spirit, given him permission to hold the exhibition in their building. The Council would endeavour to preserve a scientific record of the specimens sent; a *catalogue raisonné* would be drawn up; and drawings would be procured of such ancient and modern instruments as could not be presented for actual exhibition. It was anticipated that we might thus lay the foundation of a museum of instruments that should render a service to science similar to that which libraries rendered to literature.

A vote of thanks to the President for his valuable address was proposed, seconded, and carried by acclamation. The Society then adjourned.

On the night of the 4th inst. Dr. F. Tietjen, first assistant of the Berlin Observatory, discovered a new planet of very pale colour, belonging to the well-known group between Mars and Jupiter.

REVIEWS.

A HANDBOOK OF OBSTETRIC OPERATIONS.
By W. S. PLAYFAIR, M.D., M.R.C.P. H. Renshaw.

In ten chapters we find here treated in detail all the most important operations in midwifery practice. The induction of premature labour, turning, the application of forceps and vectis, with the various circumstances which demand instrumental and operative assistance. The dangers to be apprehended are nowhere better discussed and their treatment described than we here find them. The Cæsarean operation, hysterotomy, craniotomy, incisions, and, finally, transfusion of blood, are chapters well entitled to rank this little work with others of greater pretensions. It is eminently adapted to the wants of persons engaged in general midwifery practice, and especially those who have not the advantages of ready access to consultations with hospital physicians.

PARTURITION AND ITS DIFFICULTIES. By
JOHN HALL DAVIS, M.D., F.R.C.P. R. Hardwicke.

THE work of Dr. J. H. Davis is the result of personal experience in the life of a London obstetric physician, presenting, as he says, the "difficulties of childbirth in the history of one hundred and fifty-three labours, offering various degrees and kinds of difficulty, besides a statistical analysis of 13,783 deliveries chiefly in the Royal Maternity Charity, comprising also various forms of difficulty and complication during and after labour."

This work is well illustrated, and appears to be not only intended as a text-book for students in the class of midwifery at the hospital medical school, but as a work of reference for the mature practitioner. The faithful records of clinical cases will be consulted with advantage. It must be remembered also that Dr. Davis possesses an hereditary fund of practical experience, for his late father's midwifery practice, writings, and teaching, have perhaps contributed more than those of any other member of the profession to advance a true and safe practice in all that relates to this branch of medical art, and to place his son amongst the highest authorities in this specialty. We, therefore, recommend this work as a text-book for students and as a safe guide to medical practitioners.

CHLOROFORM; ITS ADMINISTRATION AND ACTION: a Handbook. By ARTHUR ERNEST SANSON, M.B.Lond. John Churchill and Sons.

ALL that concerns chloroform and its effects, with useful hints and advice in obstetrical, surgical, and dental operations, will be found in the pages of this work. Great pains and much labour have been expended upon it, and not the least apology is needed from the author "in endeavouring to supply a want," which it has done very efficiently. The work is very complete, and deserves, as we trust it will obtain, a very wide circulation. The chapter on "Administration of Chloroform in Midwifery" is written with great clearness and judgment.

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 24, 1866.

WHO IS A QUACK?

THE question of who is a Doctor? has frequently been asked of late in the medical journals, and has not yet been definitely answered; but the still more important question, who is a Quack? appears likely before long to receive some more satisfactory solution than it has hitherto met with. The Medical Profession, with some show of reason, regard as quacks those who profess to cure diseases without possessing the necessary legal qualifications for so doing; or those who, even if they possess some legal qualification, pretend to have discovered specific remedies, the nature of which they conceal from the rest of the world. Still, the meaning of the word "quack" is so ill-defined, that to use it in reference to any particular person may be considered libellous in the eye of the law, even although the individual may seem to deserve the appellation.

It is for this reason that even the medical journals, which aim at purifying the profession from the vermin swarming around its ranks, dare not denounce the most notorious offenders in this respect, and thus the public are left in ignorance as to the line of demarcation distinguishing the real from the false, the genuine practitioner from the spurious pretender. Even in the flagrant case of those obscene quacks, whose vile pamphlets and indecent advertisements are the scandal and disgrace of our modern British civilization, the medical journals, with a very few exceptions, have been wholly silent as to the names of the traders in infamy who are sapping the morals of the rising generation, and fleecing the credulous and the timid in all ranks and of all ages. The fear that an action for libel might be brought by any of these scoundrels against a newspaper, however honourable in its principles or pure in its objects, has imposed upon the press this discreditable but necessary reticence, and the consequence has been, that except by an occasional exposure in the newspapers as to some collateral proceeding on the part of those persons, the unguarded portion of the public is left wholly uninformed as to the real nature of the traffic in which they are engaged.

It is only right, however, that the veil should now be removed, and that, at any rate, the limits should be drawn which separate the profession from the quacks. In advising and advocating such a step, we desire no interference with individual or public liberty, for every one is free to employ a quack if he likes, but then he should be allowed clearly to understand that the person so employed is a quack. For, like vice which often attempts to pass itself off for virtue; quackery is con-

tinually attempting to pass itself off for legitimate medicine, and the empirics bedeck themselves with fictitious titles and boldly assume the rights and the privileges of the lawful and registered practitioners. The law, which professes to protect those who conform to its provisions and to punish those who disobey them, actually does the reverse in the case to which we allude, for it protects the quack in his illegal course, and by so doing punishes the true practitioner who has no chance of victory in the unequal contest.

But the law, while it thus practically ignores the claims of medicine to fair recognition, is singularly tenacious of its own rights and privileges. It would be idle for anyone to attempt to get up and plead in Westminster Hall unless he were legally admitted a member of the bar; and anyone who pretended to assume the functions of an attorney in any of our courts of law, without a certificate, would be peremptorily refused a hearing. Why, then, should the public be left entirely unprotected in the choice of their medical advisers when they are guided so carefully to a proper selection in the case of the law?

For obvious reasons we make no reference at present to any particular instance, but we may observe generally that the time appears to be approaching when in our courts of law and in the Legislature, there will be a distinction drawn between those who are honourably practising the Medical Profession and those who are usurping its functions, swallowing up its emoluments, and deceiving the public. The trickery by which the swarm of quack impostors has hitherto escaped punishment and exposure will be, we hope, speedily unmasked, and then, if the public choose to employ ignorant pretenders, they will do so at least with their eyes open.

There are at present two great classes of quacks—namely, those who are avowedly without any qualification at all; and secondly, those who pretend to possess diplomas or degrees, or who possess fictitious ones. The latter class is the more dangerous of the two, because there is in the public mind a sort of respect for constituted authority, and the man who calls himself a Doctor of Medicine or a Member of a College of Physicians or of Surgeons, is regarded as being legally possessed of the title he assumes. The community at large, when they hear a bishop preach or a curate reading prayers, or a barrister pleading at Westminster, conclude that each of these persons is legally entitled to perform his respective functions, and they take no pains to examine the clergy list or the law list to ascertain the fact: and so when Mr. and Mrs. BULL read in the *Times* that Dr. NOKES or RICHARD STYLES, M.D., has discovered a new remedy for hydrophobia, the worthy couple at once suppose that NOKES and STYLES are distinguished ornaments of the London College of Physicians or the University of London, or some other Corporation or Society entitled to grant diplomas or degrees by the law of the land. If some bold but rash journal calls NOKES or STYLES a quack, on the ground that their

names cannot be found in any of the authorized lists of the members of the profession, or that they are professing to do what they cannot accomplish, then forthwith an action is brought by the indignant NOKES or STYLES, and Serjeant GOURMAN holds up a document, perhaps a forgery, or perhaps emanating from the University of Utopia or the Carnivorous College of the Cannibal Islands, and demands heavy damages for his injured client.

As we have before remarked, this species of trickery will probably soon be unmasked, and we reserve further observations for the present. We may hereafter ask the question, whether pretenders who profess to cure all diseases, or to cure special diseases by secret methods, are not equally entitled to the name of quacks, with those who hold forged or worthless diplomas?

THE NEW MEDICAL BARONETCY.

THE speculations amongst the profession in Ireland, to which the well-deserved honours conferred on Sir WILLIAM FERGUSSON and Sir JAMES SIMPSON have given rise, have received a most welcome response. From the first it was confidently assumed that the Government intended for the medical profession in Ireland no less a distinction than it had conferred on that of England and Scotland in the person of their most distinguished members, and the election of a medical baronet amongst us was expected without hesitation. Irish medical men have reason to feel pride that their representative, as selected by her Majesty for especial honour, is as competent to take the position in which he is placed as those of Scotland and England can be. Sir DOMINICK CORRIGAN is eminently a man who owes everything to the commanding ability and power of mind, which every man has recognized and respected, whether in practice, in consultation, in Council, or in the Presidential Chair. As a public man he has been enabled to claim from every competitor the rank of talent and activity of mind; and in no position which he has filled has he condescended to a position subordinate to the leading rank. Amongst Irishmen, at least, stamp of rank was unnecessary to him, although it will be valued as a reflection on our profession.

MEDICAL GOSSIP.

I HAVE just seen an interesting report of one of those institutions, perhaps unknown in Ireland, called a "Cottage Hospital." The one to which I now allude was established at Fowey, a beautiful little nook on our wild Cornish coast and close to the mines at Par, to the population of which, as well as to the sailors visiting the ports, it has been of great and incalculable benefit, as I am enabled to verify from a visit I made to it a year or two ago, during an autumnal tour in that neighbourhood. The hospital was established little more than five years ago by Dr. Arthur Austin Davis, who states that during the past year fifteen patients had been received into the hospital, mostly cases of severity, two of which required amputation. It is satisfactory to add that all the cases did well, and what will no doubt surprise your readers is the very small working expense of the institution, which

only reached £19 0s. 10d. This is in a great measure owing to the admirable administrative ability of Dr. Davis, and to the fact that the patients are required to assist themselves by small payments when able. The financial affairs of the institution are in a very hopeful condition, as is shown in an account of the annual receipts and expenditure.

I wish I could give you as good an account of another matter introduced and constantly brought before the public by Mr. Richard Griffin, a Poor-law Medical Officer and Chairman of a Reform Association, of the abuses now pressing so heavily on all Poor-law Medical Officers in the United Kingdom. This gentleman's letter to you, published in the last number, states what I think is a disgraceful fact against all those gentlemen whose position he is so desirous of ameliorating, that during the past year he has received only £14 3s. 1d. from twenty-nine of the *three thousand and odd poor-law medical officers*. How can these gentlemen expect assistance unless they contribute towards the great expenses Mr. Griffin is incurring in their cause. Look at what only one shilling from each would produce—upwards of £150. This for a year or two would soon obtain all the concessions that are required.

Professor Huxley assisted at the first of the Sunday Evenings for the People on the 7th inst., by delivering one of his usual admirable discourses on the "Desirableness of Improving Natural Knowledge." St. Martin's large hall was crowded to excess, and upwards of two thousand were turned away; the prices of admission varied from 2s. 6d. to 3d., with the back seats free. Mr. Huxley will be followed by Sir J. Bowring, Drs. Carpenter and Hodgson, and Messrs. Heywood and Baxter Langley.

Without wishing to intrude on your hospital reporter's province, I must send you the short notes promised in my last of two operations at King's College. In that of Mr. Henry Smith, the patient was a marine suffering for six years from serious disease of the knee-joint. He had been under much surgical treatment in hospital and elsewhere, but the disease had gone on to such an extent as to produce ankylosis of the joint at such an awkward angle that the limb was perfectly useless to the man, and he was suffering much from pain, in consequence of the diseased action still going on. The operation consisted in taking out the ankylosed portions of bone, which was effected by making the incisions as practised in ordinary excision of the knee-joint, but the operation was of necessity much more difficult, as the parts were all firmly ankylosed, and there was a great amount of rigidity and thickening of the soft tissues around the joint. After a very careful operation the limb was brought perfectly straight, and the sawn parts were in complete apposition. Every bleeding point was secured, and Mr. Smith is very particular on this matter. The limb was carefully and thoroughly secured in a well-padded splint before the patient left the theatre.

In the remarks which Mr. Smith made he stated that three courses were open to him to adopt in this case. He might have made an attempt to break up the ankylosis with violent force, but to this he objected because diseased action was still going on. The next step was amputation of the limb, but it was a rule in King's College Hospital never to amputate a knee when it was possible to save the limb by excision of the joint. Therefore, he had adopted the latter proceeding. Up to this day the patient

has not had a single bad symptom, and is going on most favourably in every respect.

Sir William Ferguson's operation consisted in removing the lower jaw on both sides in front of the angle for epithelioma of that bone. The operation was accomplished by making an external cut from one angle of the jaw to the other, separating the soft tissues and then sawing through the bone on each side.

MEMORANDA OF THE MONTH.

"Tros Tyriusve."

THAT the cattle plague is an exanthematous disease is now generally believed, as also that the malady is transmissible to sheep, during which transmission it becomes milder. It seems, too, that the treatment, chiefly expectant and mildly stimulant, advised in Scotland, has proved far more successful than that in England. That the disease is carried by fomites, like small-pox, is too true, and in re-shipment of troops for Ireland, too much caution cannot be observed in guarding against the evil of such infection.

Sundry statistics and opinions on infanticide, emanating from government authorities previous to parliament meeting, have startled the admirers of coroners' court law. The Capital Punishment Commission have reported to parliament, rather unexpectedly, that it is advisable that infanticide be henceforward punished with penal servitude or imprisonment, the tests of the child having been born alive completely not required, and so of the crime of concealment of birth; a very remarkable suggestion no doubt, and doing away to some extent with the old tests of the lungs floating in water. Any marked injury to an infant newly born should be considered by a jury evidence of foul play, and punished with the minor penalty, but not that of murder.

A very detailed and able paper, by Dr. W. Farron, the "Statistics of Infanticide," has also brought up for debate the advisability of foundling hospitals as a remedy for infanticide.

It is pointed out that Dr. Chambers, and some leading journals arguing against such hospitals, from what they heard in Italy, were only in part logical, as they argue from the abuse of a thing against its cautious, careful use. M. Contino, the eminent Italian, as also Dr. Lankester, the latter who has a wide experience of the evils of infanticide in London, as we pointed out before, are both in favour of well-managed foundling hospitals, as, perhaps, the least of two evils. Of every hundred newly-born children, according to English life insurance tables, Dr. W. Farr says, twenty-six die in the first five years. In the families of peers or clergy of every hundred as many as ninety survive, but in foundling hospitals this is reversed, showing, no doubt, the evils of "bringing up by hand," and the other ills to which infant flesh is heir amongst the poor or improvident classes, and possibly still in a more marked manner in foundling hospitals. Still some good authorities are in favour of the milder expedient of such hospitals to the evils of infanticide. It is, indeed, a question whether medical men ought not always, in a balance of opinion, yield to what is most humane. These *enfants trouvés* in France, after their sojourn in the hospital, go to recruit the army or navy and for the females ample employment is found.

An agitation, calling for an improved *status* of medical

education in one of our surgical colleges, so as to keep the graduates of the latter somewhere on a level with the more or less advanced *élèves* of Pall Mall or Burlington House, has attracted notice. That we have every sympathy with the movement need scarcely be repeated.

A question of gravest importance to Poor-law Medical Officers has been submitted to the Treasury this week on the eve of Parliament, one of the good results of the late meeting of the Irish profession—namely, whether of the £114,905 which the not much admired "red ticket" system now costs (a system made so obnoxious to the country doctor by cheese-paring guardians, to save the pocket of the ratepayer, as it is usually called); whether this medical tax, about one-sixth of the whole cost of Poor Relief Act, should not be, as in England, borne in part by the Consolidated Fund: it was so recommended by a Committee of the House of Commons. The Irish Government are in favour of the change, and sensible folk here think it only requires some good man to keep the point still before Parliament to have the grievance removed. Irish Poor-law Medical men will thus be less fettered by guardians, more fairly paid, and superannuation allowances regulated. They must, however, make it their own business.

We may say here, perhaps, of our own perpendings on the point, that in some late articles admitted into the *Saturday Review*, where this and other taxes in Ireland, as contrasted with Great Britain, were examined in a somewhat exhaustive manner, it was shown vividly that such a remission of medical tax was a simple question of right, inasmuch as Ireland generally, during the last ten years, has had her taxes increased by Mr. Gladstone fully one-third (or thirty-three per cent.) over England, leaving the Irish ratepayer less able to meet this poor-rate of four shillings in the pound in many Irish towns; a rate which helps to hamper the Irish dispensary doctor, as it is not (as in England) borne in part by the Treasury. The exact figures are as 4s. 0 $\frac{1}{4}$ d., for each pound of income-tax, to 6s. 0 $\frac{1}{4}$ d.

This act, it need scarcely be said, is only one of seven acts passed, the chargeability of all which has been attached to the poor-laws—such acts as the Vaccination Act, Nuisances Removal, Diseases Prevention, Medical Charities, Registration of Births and Deaths, Expenses of Coroners, &c., under the Burial Board, and such like. In its elasticity, indeed, of late, one has seen, with something of surprise or dismay, the fever hospitals of cities like Limerick obliged to be transferred to the workhouse, almost of necessity, as the people cannot pay twice for hospitals; once, as formerly, by voluntary donation, and next by heavy poor-rates, the larger part of the latter, as regarding workhouse medical charges, taken off in England, which seems so unfair to Ireland.

But *paulo majora!* libraries and London lecture-rooms resound with gossip of another complexion, of new medical baronets, new cattle plague specifics, new lectures on "force," new Lettsoman orations on the fifth nerve, &c. So many medical men now-a-days are interested in the progress of general natural science that "memoranda" of progress would be imperfect without short glimpses of that kind.

During the week Professor Huxley delivered one of his usually placid, but difficult to digest, or heterodox discourses, which was attended by a crowd of *savans*. We had an apotheosis of "force" as the reigning principle

of organisation and vitality; man a mere accident of creation abruptly appearing in the development of the monkey; man as a savage first endowing the rocks and rivers and cataracts with "volitions" like his own (subsequently named deities and religious), and much of the same kind, so ably opposed and so happily met by our friend Dr. Acland in his late Harveian Oration. We mention such medical essays indeed in sorrow, rather to direct attention to the latter oration than the former—bane and antidote, verily.

Professor Owen has been busy in a revival of the Dodo from its bones, as also welcoming back M. Chaillu a week ago, and last, not least, finishing up a discussion with Mr. Flower, as to the cerebrum of the monotremes. Flower right and Owen wrong. We have had the irrepressible *cocon* also on the *tapis*, a fierce debate between Mr. King, of the College, Galway, and Dr. Carpenter, as to whether this animal is not a mineral, the incidental fact coming up (*teste* our full-blown friend, Sir R. Murchison) that the Connemara marbles of Galway are wrongly described in Ireland as Laurentian, whereas they are Cambrian. As our motto would fain be that excellent one—*petionus damusque vicissim*—to give and take, we take some comfort in such differences of opinion.

Dr. Bence Jones—*intervallo longo*—continues his payable in another direction on force and suboxidation, or rather on interstitial nephritis and alcohol as the chief causes of Bright's disease, with much of a practical nature on that malady. Alcohol, he believes, increases oxidation, followed as it is by uræmia, with deficiency of blood globules, exudation of urea (as shown by foul breath, sickness, and diarrhœa), gout, cramp, coma, &c., all well described. The chief remedies he has found useful are purgatives and diaphoretics to arrest the tendency to coma, and chloroform to lessen the severity of convulsions when they threaten in certain stages of the disease. It is observable that Dr. Bence Jones, in a manner rather pompous, has never replied to the scathing comments of Dr. Lionel Beale on these questions of vitality being in every particle of matter mere chemical oxidation or non-oxidation.

Dr. Andrew Clarke, the indefatigable microscopist of the London Hospital, whose views were chiefly, if not alone and first recognized by the CIRCULAR, sends a vivid reclamation this week of his thoughts, alleged to have been appropriated by Waters of Liverpool, on pneumonia, but not detected in a late debate in the Medico-Chirurgical Society.

The passing literature of cholera, seeing that many expect it again this year, deserves notice. An article in *Fraser* this month describes the panic and horrible exaggeration as to its contagiousness, which worked incredible mischief at Malta, and led the Emperor of the French to counteract such a feeling by visiting the Paris hospitals. Another essay in *Macmillan* gives the true history of the Broad-street pump, on which a dusty German Pettenkofer has built up an ingenious hypothesis, that the soil must be porous, permeable to air and water, impregnated with excrementitious products, and that the cholera "germ" must undergo decomposition about the eighth or tenth day before it acquires its poisonous properties, and yet how many localities have we where these conditions exist as to soil, air, water, excrementitious products, and yet no cholera?

MacPherson, on the other hand, tells us cholera in India

is far more prevalent in dry than wet months, more common (as 76 to 24) in the floating than fixed population of Calcutta, especially in the new arrivals from sea. All authors seem to agree that in hilly situations, where there is much rock and thin shallow soil, not permeable to excrementitious matter, cholera is absent; this was also well seen in London as to cholera at Lambeth and cholera at Hampstead. We are no doubt on the road to some new facts in the etiology of this terrible disease, so long the opprobrium medicorum. Some unexpected source of the malady may reveal itself, such as the recently discovered origin of many fevers in houses, the decomposing turf and coal-slack in coal cellars.

Dr. Brown-Séguard talks this week of various nerve fibres, so many as eleven in the spinal cord, their anæsthesia, hyperæsthesia, &c. He differs from Handfield Jones and Lister. He has found a strange thing—*viz.*, that the excitability of the same nerve varies in different parts of its length, and that this, as well as that of the muscles and cord, may be very much increased at the same time that the force developed is very small, a fact shown well in atrophied muscles.

SCURVY IN THE MERCANTILE MARINE.

THE attention of the public has been repeatedly called to the continued prevalence of this disease in the mercantile marine, and, in a medical retrospect of the past year, it is again prominently thrust upon our attention. By a return just made, by the resident medical officer of the *Dreadnought*, in the Seaman's Hospital Society, we find that the numbers of entries for scurvy on board that ship in 1865 largely exceeds the annual average return of the previous ten years, and that all these cases, with one exception, have been brought from ships carrying the British flag. This, of course, but feebly represents the actual amount of scurvy imported into London, and returns from hospitals in Liverpool still remain to be added to this unseemly list of avoidable diseases. The attention of the Board of Trade has been prominently directed to this subject, and a recommendation has lately been made by them to the Local Marine Boards with a view to the appointment of inspectors of liquorice. A majority of these Boards, however, have sent unfavourable replies; and, as men and property on the seas are alike endangered by the frequent presence of this disease in homeward-bound ships, it is of paramount importance that a remedy, at once simple and efficacious, should be provided and enforced by legislative interference. It is imperative that lime and lemon juice shall be good, properly stored, mixed with a certain proportion of spirits, and regularly (*i. e.*, daily) given out to the crew. The last only of these necessary items of arrangement is provided for by the Merchants' Shipping Act, and this is almost habitually disregarded. Few can tell to what an alarming extent men are temporarily reduced and permanently enfeebled by this disease, for it is now practically confined to a certain class only, the medical treatment of which class *en masse* comes under the notice of but few practitioners. But, as we enact laws and root out abuses, with a view to correct the sanitary state of our land community, it is but fair that the denizens of our wooden walls should receive some small share of our attention and regard, contributing as largely as they undoubtedly do to the commercial prosperity of this country.

SENSATION AND CATTLE PLAGUE.

WE verily begin to fear that in the matter of cattle plague our common profession may get itself into bad odour, instead of reaping that *éclat* which really seems almost within grasp. We feel bound to utter a caution against the railroad pace at which suggestions, interpretations, and theories have been started and then defended by quickly gathered and incomplete facts, during the last few weeks. The ignominious failure of the homœopaths in their handling of every matter connected with the rinderpest ought to put us on our guard against failure. It is essential to the establishment of truth, and to the preservation of the utilitarian character which medical inquirers should possess, that we set our faces steadily against the prevailing spirit of the age—sensation; yet we think we observe something more than the mere germs of that principle abroad amongst us. It has evidenced itself plainly enough in the appeal lately made to the public through the columns of daily journalism, as though it were a short cut to fame to get one's name in connexion with some supposedly novel occurrence printed there. For the while a little notoriety is attained, but mediocrity, and perhaps insignificance, are often to be the final effects. Patient, careful, and persevering observation alone is the means by which any satisfactory knowledge is acquired. Our remarks apply as well to the press generally as to individual contributors. Contrariety of opinion no doubt is conducive in the end to the establishment of right and correct views, but it should be accompanied by a fair balancing of *pros.* and *cons.* We beseech our medical friends to prosecute further researches in a proper spirit, and with that amount of cautious reticence as regards conclusions which the gravity of the subject fairly demands, otherwise rinderpest will become so complex, on account of counter and contradictory statements, that vast labour and time will be expended in unravelling the mistakes of our own committing. At the present moment there is clearly a tendency in observers to range themselves into distinct antagonistic positions, and to regard the rinderpest from totally different points of view in fact, because by this means individually they may acquire notoriety the more readily. In affirming thus much no accusation of any blameable kind is implied, it is simply a failing human nature to do so.

Now, how stand matters? Almost every one is agreed that the rinderpest is an acute exanthematous disease, its general features offer no objection to the possibility of its being small-pox. Not so with the eruption, however. Now, firstly, it must be remembered that most of the cattle die at a period anteriorly to that at which the eruption of small-pox is developed so as to be appreciable to the senses. Secondly, it, as a rule in the cow, does not assume the peculiar vesicular character which we are led to believe is a diagnostic feature. It has been argued that the texture of the skin of the ox accounts for the difference, and other points we noticed last week. If we regard the history of small-pox as to its eruptive state, we shall find a very wide range of variation. The results of vaccination are most important. Dr. MURCHISON has collected, up to the present moment, an amount of evidence upon this point which, though it is not very great *per se*, yet cannot be overlooked or disregarded. The preponderance of testimony in favour of the protective influence of vaccination *contra* rinderpest is undoubted.

It has struck us that neither the matter from human variola, nor that obtained from the vaccine pustule of the child, are the most suitable and proper kinds to be used for experiment. By analogy of the human subject it would appear that the matter of cow pox is most fitting to protect against the greater form of mischief, in the same way that vaccinia acts against variola. In a few weeks decisive results must be obtained.

Another matter, however, has startled the attention within the last few days. When Dr. FENWICK addressed a letter to the *Times*, stating that he had discovered in the muscles of cattle who died of rinderpest, small entozoa, some people imagined not only that it was a novel discovery, but that the cause of the cattle plague was solved. It is affirmed that these bodies are found in healthy animals and are quite independent of rinderpest. German observers found them upwards of twenty years ago, in the mole, the rat, the deer, and other animals, and Mr. Rainey, in the pig in 1857, imagining them to be the early stage of *cysticercus cellulose*.

Dr. BEALE, who has gone most intimately into their microscopic history, thinks they are at any rate more abundant in the muscles of rinderpest than healthy animals. This season has been peculiarly prolific in the production of all low forms of life, and it becomes a question whether this would not account for their greater prevalence. They appear to be simply elongated sacs, covered on the outside with ciliated processes, or rather hairs, and filled with young cells of an uniform size, slightly curved and larger at one end than the other. They lie amongst the elementary fibres, occasion no irritation, and reach sometimes a sixth or a quarter of an inch in length. They exhibit no trace of alimentary canal, gland, or other organ in their interior. The effect of reagents upon them shows them to possess the attributes of animal rather than vegetable structures; though Dr. COBBOLD has expressed the opinion that they are probably of vegetable nature. It is difficult to subscribe to the latter view, in consequence—first, of their situation; secondly, the peculiar cilia-like outer coat or test; and thirdly, the effect of reagents, especially iodine and liq. potassæ. They are clearly very definite things, as Dr. BEALE observes, and deserve to be most carefully studied. With regard to their connexion with cattle plague, little at present can be said beyond the fact already mentioned, that competent and trustworthy observers declare them to exist in perfectly healthy muscular structure. If they be entozoa, it is difficult to conceive how the connexion can be traced, inasmuch as they must take, one would suppose, pretty good time to grow to the size of an eighth or a quarter of an inch, and get filled with the enormous number of young cells which distend their interior.

Against the relation of rinderpest and small-pox may be mentioned the fact that Mr. CEELY has failed, "in the few cases in which he has attempted inoculation with the nasal discharge in cattle plague on subjects not having previously undergone variola or vaccinia," to produce any result. At the same time one remarkable affirmative instance occurred in the case of Mr. HANCOCK of Uxbridge.

It cannot have escaped the attention of our readers that vaccination is being practised largely in different parts of England, and that the public have taken the thing entirely into their own hand, which is much to be

regretted. It only shows that excitement is strung up to a very high pitch, and when this is the case cool judgment is considerably warped and unbalanced. A contemporary justly remarks that in this matter the cart has clearly gone ahead of the horse. We mean that people have taken bit in mouth and run clean away from our Cattle Plague Commissioners. It is high time that they lay down some very definite rules for the guidance of those who perform the operation of vaccination upon the cattle, otherwise a really protective method of treatment may get into discredit, and be nullified simply from error in executive detail. We should also like the careful observation of the characters of the eruption of the rinderpest entrusted to the hands of an experienced dermatologist.

Once again we implore observers to treat this matter in a truly scientific spirit, and to exercise the largest degree of caution, before they rush into print or otherwise give publicity to novel opinions.

MEDICAL ANNOTATIONS.

WORKHOUSES AND LUNATIC ASYLUMS.

WITHIN the last few days the public have been horrified by the revelations made as to the misery, the filth, the wretchedness endured by the unfortunate paupers in our metropolitan workhouses, and as to the systematic neglect experienced by this helpless class of the community. On seeing the gloomy rooms occupied by the paupers, sick or well, old or young, and the utter absence of any of that sympathy which they ought to receive from their "Guardians" (?), we might well exclaim with the poet "*Lasciate ogni Speranza, voi chi què entrate*." But let us turn to a lunatic asylum (a pauper one, be it remembered), and note the contrast. The *Times* of Thursday last occupies two of its columns with an account of a dramatic entertainment, supper, and ball given to the inmates of the Colney Hatch establishment, and the following is an extract from this graphic sketch. In another page of the very same paper the details are given of an official inquiry into the treatment of paupers at the Bethnal-green Workhouse. "Look hereupon this picture and on this":—

"There were about 700 of the inmates present throughout the entertainment, and a more orderly audience could not have been assembled. From beginning to end there was not the slightest interruption, and the patients exhibited remarkably good judgment in the bestowal of their applause. Perhaps the most interesting circumstance connected with the performances was the manner in which the delighted patients joined in the choruses of the comic songs. Mr. Moreton requested them to do so, and it might have been supposed that at least some of them would begin at a wrong place, or that all would not commence together; but no such mistake was committed. They took up the right note, and sung in a pleasing and harmonious manner. At the conclusion of the burlesque Mr. Wyatt, the chairman, and his brother visiting justices entertained their guests, while the patients were regaled at supper—cakes, oranges, figs, and other delicacies being provided for them. After supper there was a ball, at which the visitors, the officers of the establishment, and several hundred of the patients were present. Ladies of the families of county magistrates took patients for their partners, and the gentlemen danced with inmates of the asylum. Waltzes, polkas, and quadrilles were gone through without confusion, and the intricate Lancers accomplished with fewer mistakes than one often sees committed when they are danced in an ordinary ball-room. An excellent band was in attendance, the great hall in which the ball took place was brilliantly lighted, and the whole scene was as foreign to what one might expect to witness in a madhouse as anything that can be imagined. That such an evening can be spent in a lunatic asylum is one of the results of what may be called the "palliative" system. It can scarcely be called 'curative,' because, said

to say, the number of permanent cures of chronic insanity bear but a small proportion to that of those afflicted with the malady. Very many cures are, however, effected in our asylums; and the duration of life has been lengthened among the insane by the treatment in these establishments. More important still, their existence is rendered as happy as it can be under their heavy visitation. The fact that a though there are at present in Colney Hatch between 500 and 600 persons who had attempted suicide before their admission not a single inmate died through suicide or violence from another during the whole of last year tells favourably for the vigilance of the attendants. In their intercourse with them last evening the patients showed no fear of the officers. On the contrary, they appear to look upon the doctors, and those acting under them, as their personal friends. The company broke up at about ten o'clock; and if the visitors had not enjoyed an evening of unalloyed pleasure, certainly they enjoyed the satisfaction of having contributed for some hours to bring happiness to a number of their afflicted fellow-creatures who can do little to even temporarily cheer themselves."

The following extract is from the Poor-law Inquiry in Bethnal-green, from the same day's paper:—

"Pierce, the labour-master, gave evidence confirmatory of the changes of suits having taken place between incoming paupers and outgoing paupers who had been sick, and he said the stores of clothes were occasionally deficient, owing, in a great measure, to the 'cord' suits being away at wash.

"The Commissioner said he would not prolong the inquiry, but he desired to say a few words to the guardians. First, with respect to the bathing, he desired them to consider how essential it was the water should only be used once, when there was so much typhus among the lower classes, and that this was likely to be spread by persons bathing together. This typhus, he warned them was a species of plague, and one most likely to be spread by the treble use of one water as by the use of the shirt among the casuals. He hoped that the guardians would look to these matters, and try and prevent typhus spreading by these means. On passing through the wards the day before he had his attention attracted to the large number of children (300) in the wards. He desired the guardians to consider whether it would not be well for them to follow the example set by other London unions, and send the children away to district schools in the country, where they would be brought up without the associations of the 'union.' He could assure them that children brought up in the London unions in after life looked upon those places as their homes, and flocked there when out of work. Then, another thing; children brought up in the workhouse and sent out to places were beset with parents in many cases, who dogged their offsprings' steps, and, having lured them from their situations and stripped them of their clothes, sent them back upon the workhouse nearly naked. Then there was another point; the wards occupied by these little ones were required for other inmates, and sending the children away would make the necessary room."

NATIONAL FEVER HOSPITALS IN LONDON.

The Guardians of the parish of St. Pancras have applied to the Poor-law Board on the subject of erecting Fever Hospitals in London at the public expense, and have adduced several powerful reasons in support of this proposal. The London Fever Hospital in the Liverpool Road, Islington, is often overcrowded, and the consequence is that fever patients are refused admission, and sent back to the workhouses or other places, where they propagate the infection. It is also urged that the provision of accommodation for fever patients ought not to be a matter of private charity, as is now the case in London, but a national concern. Notwithstanding the arguments of the St. Pancras Guardians, however, we do not altogether concur in the propriety of erecting these public Fever Hospitals, which we think ought to be provided by the respective parishes. The fact is, that the local authorities have been culpably remiss in almost all cases in the prevention of fever and other infectious diseases, their negligence being generally cloaked by the plea of economy. Without advocating any special plan at present, we are inclined to think that temporary and isolated dwellings for the reception of

cases of fever, small-pox, cholera, or other such cases *when they occur*, would be far more desirable than permanent national buildings for the reception of any one class of cases. This plan has frequently been recommended, but we believe never has been followed.

NATIONAL HOMŒOPATHY.

Under the serious visitation of the cattle plague, which is now afflicting many of the nations of Europe, it may seem trifling to advert to the inanities of homœopathy in reference to this disease; but a letter recently written by Lord Sidmouth, and published in the *Times*, is so ridiculous that we are compelled to notice it. This nobleman, who appears to be one of the followers of the homœopathic delusion, accounts for the failure of the globulistic treatment in England, compared with its alleged success in Holland, by the assertion that the *right* homœopaths have not yet been consulted. The real Simon Pures are, it seems, Messrs. Sentin and Gondoy of Holland, who are said to possess the only true specific globules, of the nature of which all the other globulists are ignorant. Hence the failure of the British homœopaths, and hence the generous offer which has been made by Messrs. Sentin and Gondoy to come over to England at the small charge of £100 each, exclusive of expenses, for the purpose of curing our afflicted cattle. Thus there is not only an English and a Dutch homœopathy, but there is a real Dutch homœopathy and a sham one, and it is really very difficult to know which is which, they are so much alike. As Burns says, "If fate would but the giftie gie us, to see ourselves as other see us," Lord Sidmouth might perhaps discern his own folly, and at least refrain from parading it before the eyes of the public.

VACCINATION FOR RINDERPEST.

It is well known that during the last week or two, a theory has been proposed as to the strong similarity, if not identity, existing between the cattle plague and small-pox. We have noticed this very important matter in our columns, but have not given in our adherence to the views thus advanced, and without wishing to discourage speculation, we may state that we are very sceptical as to the analogy of the two diseases. The practical deduction to be drawn from such a suggestion would be that, as vaccination prevents small-pox in the human subject, so the same measure adopted in the case of cattle would prevent the rinderpest, and accordingly we find that the vaccination of cattle is now being performed to a very great extent throughout England. Rules have been very properly laid down as to the due performance of the operation, and in many cases, we are informed, the vaccination has been successful. But the question now at issue is, not whether vaccination can be successfully performed on cattle, but whether that operation will prevent the cattle plague, and on this point we believe that the evidence at present is completely negative. We hope, however, that we are incorrectly informed, and shall be only too happy to acknowledge our error.

RETROSPECT OF THE JOURNALS.

STILL the cattle plague. The periodicals are filled this week with original communications representing different views as to the nature of the "pest." These are backed by letters from different parts of the country, advocating the adoption of one or other of the most contrary opinions. In reading these communications one is put in mind of the position in which a non-professional person is placed on listening for the first time to a trial in a court of justice. When he hears the case of the plaintiff stated and his witnesses examined, he thinks there is not a worse used individual in the universe, but on hearing the de-

fendant's case his ideas are completely changed, and he is fully impressed with the idea that the plaintiff has represented a tissue of falsehoods. He is again *nonplussed* at the reply of the plaintiff's counsel, and finally he is utterly confounded with the address of the judge. So it is with this cattle plague dispute. The *Lancet* adopts Dr. Murchison's views as to the identity of small-pox and rinderpest; and, certainly, if we read the letters and evidence from farms in the more northern counties, there is every reason to think that we have, through his untiring zeal and perseverance, come near the truth. It seems that the proper method of vaccination is to obtain the lymph from the matured pustule in a child. One cow is inoculated from it, and the rest of the herd with the matter taken from the first beast. Dr. M. recommends Dr. Vaughan's plan:—

"Lastly, Dr. Vaughan of Crewe, who is public vaccinator to one of the districts in the Nantwich Union, and who has vaccinated a very large number of cattle, has not had more than ten per cent. of unsuccessful cases." He writes thus:—"I employ in the first cases ordinary lymph from the arm of a child, and afterwards from beast to beast. My mode of operation has been this. I select as the most convenient spot, both as regards facility of operation and protection of the vesicles, the portion of skin devoid of hair by the side of the vulva. Drawing the skin tightly over the ischial prominence, with the point of a curved bistoury I make from three to five slight incisions, about a line in depth and half an inch long. These do not bleed, but exude sufficient serum to dissolve the lymph dried on the points, when such are used (though I prefer tubes). Having introduced the lymph, I loosen the stretched skin, and the incisions close so as not to be visible, effectually imprisoning the deposited virus. In this way I have produced by the eighth day (occasionally by the fifth or sixth) as many as six well-matured vesicles exactly resembling those produced on the arm in infant vaccination, and yielding lymph in such plenty that I have vaccinated sixty beasts with the lymph procured from one. The vesicles, with their surrounding subcutaneous effusion, have raised a swelling equal in size to a florin or half-a-crown. I have not observed any particular constitutional symptoms."

The *Medical Times* adopts the views put forward by Dr. Ferwick, that the plague is due to the infiltration of the tissues with *entozoon-like* bodies; and, although there is some doubt as to the exact nature of them—whether animal or vegetable—still it is a remarkable fact that the majority of post-mortems on animals has revealed the almost universal presence of these bodies. Dr. Lionel Beale has taken the matter in hand, and from his great skill and success in microscopic research we are to take anything from his pen as a valuable addition to our knowledge. He has found these masses enveloped in a layer of muscular tissue and sarcolemma; he does not, however, pledge himself to the fact that they are *entozoa*.

"The facts concerning these entozoa(?) may be summed up as follows:—

"1. That in almost all, if not in all, animals dying of cattle plague, entozoa or entozoon-like bodies exist in considerable number in the voluntary muscles of the system and in the heart.

"2. These or closely allied species have been known for more than twenty years, but their nature has not yet been determined. They have been found in the ox, sheep, deer, pig, rat, mouse, and perhaps other animals.

"3. They are occasionally found, but in very small numbers, in animals apparently in perfect health when killed.

"4. In the muscles of a calf killed by cattle plague, under *six months* of age, these bodies were found in immense numbers.

"5. They vary in length from less than the 1-300th of an inch to at least a quarter of an inch in length. They are, for the most part, embedded in the contractile material of the elementary muscular fibre, but they are occasionally found free.

"6. They are for the most part spindle-shaped, and the external investment or envelop exhibits a very delicate and peculiar structure, being completely covered with delicate hair-like processes.

"7. The mass within appears granular to low powers, and exhibits a division into numerous segments, but it is found to consist entirely of minute bodies re-molting one another, possessing very definite characters, less than the 1-2600th of an inch in their longest diameter, and of peculiar form, being oval, flattened, the body slightly curved laterally, with one extremity blunt and the other almost pointed.

"8. The entire mass increases in size as these small bodies increase in number, probably by division and subdivision, within the cyst."

In the *British Medical Journal* there is a capital paper from Dr. Dobell, on the "Nature, Cause, and Treatment of Tuberculosis." He is a painstaking observer, and has worked at his present subject for sixteen years. It is not to be expected that all physiologists and pathologists will agree with him, but he puts forward his hypothesis so clearly and modestly that no one will find fault with him. He seems to think that diseases of this class are due to impairment of the functions of the pancreas. An idea of his proposition may be gathered from the following:—

"Tuberculosis is due to defect in the action of the pancreas on the fat taken as food (especially the solid fat). The supply of properly prepared fat is cut off from the blood: 1. by the fats not being brought into a proper condition by the pancreas; 2. by loss of absorbing power in the small intestines, due to the contact of unhealthy pancreatic juice and of defectively prepared food with its mucous membrane. Thus the blood becomes deficiently and defectively supplied with fat-elements from the food; is unable to afford those required for direct combustion; does not replace those taken up during interstitial nutrition; but, on the contrary, takes up more to compensate the deficient supply from the food. This having gone on up to a certain point, the fat-elements of the albuminoid tissues are seized upon, and these tissues are minutely disintegrated in the process. This disintegrated albuminoid tissue is nascent tubercle; and this process of disintegration is tuberculisation."

Dr. Tubbs gives the particulars of a case of labour induced by the use of Barnes' dilator; the proceeding was called for by the occurrence of hæmorrhage during the eighth month. Many may condemn the practice of "turning" in a case of the kind, where it was known that the child was dead for hours.

Dr. Kratz's account of the outbreak of trichina disease at Hedessleben, in Saxony, is very harrowing. We may congratulate ourselves that the lower orders of this country are not in the habit of eating raw pork. Out of about 350 cases there were 80 deaths, and the probability is that there will be more. In many of the cases the diarrhœa was not a prominent symptom; there was œdema of the eyelids and tension of the flexor muscles of the extremities and neck. Death occurred in about four weeks, from paralysis of the diaphragm.

Dr. Maclean, in the *Canada Medical Journal*, relates a case of fracture of the larynx followed by œdema, requiring tracheotomy.

In the *American Journal of Medical Science*, Dr. Cutter of Newark, relates a case of ligature of the common iliac.

A death from the administration of chloroform has occurred at St. Mary's Hospital.

Sir J. Simpson's eldest son is dead.

In the *Lancet* Mr. Coote gives his views on syphilization. Although he adduces no facts to prove the want of efficacy of the system, he objects to it principally from its tediousness, as might be expected. None of his patients would allow the treatment to be completed.

Dr. Ellis relates a rare case of carcinoma of the cellular tissue about the kidney, in a boy aged seven.

At the Kidderminster Hospital a weaver whose clothes were caught by machinery, has had the skin of the penis completely dragged off and the organ buried in the scrotum. This is not a very uncommon accident.

At the Obstetrical Society Dr. Eastlake recommends a substance called *iodoform* as a valuable local and internal remedy for procuring respite from the pain in cancer of the uterus.

On the subject of Workhouse Infirmaries, which has attracted such notice in London from the cases of death which have lately been published, in which it is believed neglect formed an element, the *Lancet* is of opinion that those institutions are overcrowded and under-officered. The very same may be said of the similar institutions in Dublin. In the North and South Unions we believe we are right in stating that each of the medical men are fully two hours engaged each day in getting over their work. It is only rational to suppose that where such a time is occupied the medical officer is anxious to get out of the place much too soon; the number of patients in charge of each is too large. In a general hospital there would be at least four surgeons and four physicians to do the same work.

The *Lancet* warns us against "Brahee sugar," which now turns out to be a secret remedy and not altogether free from the taint of homœopathy. It acknowledges that it was "taken in" in allowing the correspondence in reference to it to appear.

In the *Medical Times* we find four successful cases of ovariectomy.

We are sorry to find that scurvy, a disease which was almost banished, is on the increase in the merchant navy, probably owing to the inferior quality of the lime juice.

The famous Dr. Hunter, of advertising notoriety, has again appeared in court in an action against the *Pall Mall Gazette* for libel.

We are promised a host of correspondence in next week's journals in reference to the abuse of chlorodyne by the *Medical Times and Gazette*.

POSTPONEMENT OF THE PROPOSED BANQUET TO SIR J. Y. SIMPSON.

A VERY influential meeting was recently held in Slaney's Hotel for the purpose of making arrangements for a banquet to Professor Simpson, and a committee comprising gentlemen of all professions, and representing all classes of society, was then appointed. The Earl of Dalhousie had willingly consented to preside on the occasion, and it was resolved that the dinner should come off on an early day. The sudden and most melancholy death of the Professor's eldest son has, however, in the meantime put a stop to the preparations. We trust that ere long, nevertheless, the profession and the public may have an opportunity of manifesting how much they appreciate the services of the distinguished Baronet.

CHILDRENS' HOSPITAL FOR GLASGOW.—We are much pleased to learn that active steps are now being taken for the erection of an hospital for sick children in the western metropolis, and we understand that a public meeting is soon to be held for the purpose of exciting public interest in the movement. The promoters have already considerable funds in their hands, and we have no fears of the success of the hospital in a city which always subscribes so liberally to every good and charitable cause.

IS RINDERPEST SMALL-POX?

It is a singular fact that Dr. Murchison, whose pathological investigations have done so much to complete the separation between our three different continued fevers, which up to recent times have been, and still occasionally are, confounded together as one, should have lent his name to the theory that rinderpest and small-pox are identical, mainly, apparently, because both are attended by a pustular eruption. No one knows better than Dr. Murchison that the mere similarity of an eruption in any two diseases is not a proof of the identity of these diseases. To prove this there must be identity of the type of fever as well as identity of the eruption. No one has even attempted to show that the fevers of variola, vaccinia, and rinderpest are identical in type, and no one has ventured to prove that the eruptions are identical. The vaccine vesicle, like the variolous one, is, if true, always umbilicated, and in its early stages consists of an umbilicated multilocular cyst containing serum, around which spreads the rosily areolar rash. In rinderpest the fever does not remit, is always continuous of a low typhoid type, while the eruption either consists of simple conoid vesicles, or of true pustules, and never of umbilicated vesicles passing into pustules. The fact that inoculation of rinderpest virus produces a pustular eruption in man proves nothing. Dr. Henri, in his work on "vaccination," states that there are no less than six vesicular eruptions in the cow which can be communicated to man, only one of which is prophylactic of variola. M. Prüg of Saxony, Messrs. Clarus and Radius, Hildenbrand of Vienna, and many other authors make similar statements, so that this fact must go for nothing. Further evidence is daily accumulating that a previous attack of variola does not prevent animals from taking rinderpest. At a recent meeting of the Justices in Forfar, Lord Dalhousie stated that two cows, belonging to Dr. Guthrie, the Provost of Brachin, had cow-pox so bad last year that they could not be milked; recently they took rinderpest, and he was understood to say had died of it. In a private letter from the chief inspector of rinderpest in Forfarshire, he writes:—"I have just visited one place in which were six cows, who had natural cow-pox within the year, and yet were all suffering from rinderpest. As formerly remarked, the true nosological position of rinderpest has yet to be determined, and further and more minute inquiries into the nature of the fever and of the eruption must be made before this can be satisfactorily settled. Meanwhile we regret the promulgation of this theory of Murchison's, as tending to render both Government and the public vacillating in their application of the only effectual cure—the pole axe—to which both are rapidly tending. As interesting in the present conjuncture, we append a letter from Mr. Fisher, a Perthshire farmer, which has appeared in a portion of the public prints, and which contains a great amount of sound sense in regard to this matter:—

"I am perfectly satisfied that all my cows had the cow-pox last summer (some of them very badly). I cannot say that the calves had it, but as they were running occasionally with the cows, and drinking their milk when they were in that state, it is more than likely they had it, if it is at all infectious. I am happy to state that they are still all well, and I hope they may continue so. Most of the farms all round have been infected, and some of them cleaned out. In the beginning of October, when the plague began to spread in this district, I put my cattle into the byres, and since then they have never been out. I have been very careful that no one should go near them but the man who feeds them, and he never leaves the farm. They drink from a trough in which iron is placed and sulphate of soda mixed daily, and the whole byres and courts are daily sprinkled with chloride of lime and Macdougall's disinfectant. I have seen all that has been written in the papers regarding the small-pox, and, knowing my own case, I was in hopes a cure might be found; but I have been making inquiries since, and I find that a herd of cows in my neighbourhood are all

swept away but three, and the farmer says they had the cow-pox last summer. Now, if this is correct, there cannot be much in vaccination. My own opinion is that it is a low fever, very infectious, and that the only safety is in keeping clear of it. I may be wrong; but, I think, the fact that I put my cattle into the byres so early, and allowing no one to go near them since, with the liberal use of disinfectants, has as much to do with my being all right at the present time as to my cows having had the cow-pox during the summer."

It will be seen that Mr. Fisher has not much faith in cow-pox as the preserving agency in the case of his cattle, but that he attributes his good fortune to the prophylactic and isolating measures he has adopted.

Since the foregoing observations were penned, we learn on unquestionable authority that of the calves whose immunity from the disease formed the ground for Mr. Tolle-mache's letter to the *Times* on the efficiency of vaccination, one has since taken the disease by contagion, and the other by being kept in a vitiated atmosphere—Ed.M.P.C.

AN APOLOGY.

It would be disrespectful to our Subscribers to hesitate at offering a sufficient apology to them for our shortcomings within the last three weeks in punctuality, and in other respects in which complaint ought not to be possible or apology necessary. With the most anxious desire to render THE MEDICAL PRESS AND CIRCULAR as perfect as possible from its first number and in all respects, we must confess that the magnitude of our task has, in individual cases, overcome our desire and intention to do full justice to all our subscribers, contributors, and advertisers. In those days of publication by millions, little latitude can be allowed for failure in any respect, yet we suspect that the general public have a very short idea of the full meaning of an issue of 17,000 copies of a three sheet journal. When we say that after leaving the compositors' hands such a journal has to go through thirteen separate operations before it reaches the Post-office, and that from the 3rd inst. to the 18th, no less than fifty-two sacks full of copies have left our office, it will be understood that delay in transmission or faults in typography are indispensable. The publication of three separate and distinct journals, each comprising its own special material and information, is an undertaking of sufficient difficulty and responsibility to account for some little slowness or harshness of working in its machinery, and we trust that our readers will not be slow to extend to us an indulgence which we hope it will never again be necessary to ask from them. We have spared neither labour nor expense in the execution of our promise, and in point of fact have exceeded our estimated issue by nearly two thousand copies.

UTILISATION OF SEWAGE.

WATER-CLOSETS, as now managed, are an utter nuisance. The matters deposited in them ruin the air of houses, and when they reach the sewer poison the air of streets, and when they reach the river or the sea, further poison and defile the waters therein. Nevertheless, sewage matters are a very good thing in their own place, that is in the oil, and nowhere else. In Belfast for example, not to mention other Irish, English, and Scottish towns, the sewage matters driven into the sea, kill the sea infusoria, and a joint deposit of the sewage matters and dead infusoria takes place, and has

taken place, to an immense extent on both sides of the Lough, creating a stench, especially when the tide is out and the sun is war.n, which it is impossible to describe, and which, even now, renders an abode on either side, for some miles down, anything but agreeable.

The proper plan would be to collect *all* sewage matters in close vessels, wherein they might be disinfected by the addition, by hand, of a little carbolic or phenic acid, now sold very cheap by Calvert in Manchester, or simply of dry earth. Or, one or other of these substances might be added by some simple mechanism as connected with the seat. In Belgium as in China, necessaries are erected all along the highways, for the convenience of wayfarers. The system might be followed here with much advantage, both in town and country. As it is, human ordure, almost everywhere, pollute our streets, disgrace our roads. In China and in Japan every particle of human excrement is carefully collected and restored to the soil, although, unfortunately, they have not got the length of disinfectants and deodorisers. In the Appendix to Liebig's "Laws of Husbandry," as translated by Professor Blythe of Cork, will be found a most interesting account of the collection and application of sewage matters in Japan, where, in respect of this careful collection and thrifty application of sewage matters or rather human feculence to the soil, they excel every community, except perhaps the Chinese, in the whole world. Their example cannot be too universally followed with, however, the addition of those appliances and precautions suggested by modern science and modern delicacy. With this proviso, every farmer should be furnished with a printed slip of instructions from the Appendix already cited.

POOR-LAW MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Since the last report published in your journal I have received £7 3s. 6d., as the annexed list will show, which not only places the Association out of debt, but leaves a small surplus for future proceedings. To this surplus I trust the Poor-law Medical Officers generally will add their subscription, and thus enable the Association to take active proceedings during the ensuing Session of Parliament.

There is a question now before the country to which I desire to call the attention of the Poor-law Medical Officers—viz., "The Rinderpest," which, should it be proved to be a malignant form of small-pox, will compel the Government to consider the question of the compulsory vaccination of all calves, not to be killed as such, and thus prevent the spread or reappearance of the rinderpest in the United Kingdom.

Should such be the case, and the Poor-law Medical Officers not consider it derogatory to vaccinate these animals in their respective districts, a very material addition might be made to their at present miserable incomes; besides this, it would be the means of keeping up the supply of 1, mph for the human subject. If, however, they should decline to do this, I feel certain that those who are deputed to vaccinate the calf (a much more difficult operation than that in the human subject) will after a time vaccinate the infant, and thus a material reduction instead of an increase may be made in the fees of the Poor-law Medical Office s. I throw this out for the consideration of my brethren, that steps may be taken to ensure the attainment of this object should they desire it.

R. Griffin, Weymouth, £1 1s.; H. T. Matthews, Horsham, £1 1s.; C. F. Lewis, Horsham, 5s.; W. Martin, Horsham, 10s.; R. Harrison, Kendal, 5s.; A. Cheeves, St. Germans, 5s.; H. E. Sargent, Launceston, 5s.; H. B. Gould and W. B. Norman, Portsea Island, 10s.; W. A. Raper, Portsea Island, 5s.; J. T. Allnut, Portsea Island, 5s.; J. E. Brne, Shaftesbury, £1 1s.; J. H. Swain, 10s.; W. H. R. Bennett, 10s.; J. S. Miles, 10s.—1 an, &c.

RICHARD GRIFFIN.

12, Royal-terrace, Weymouth, Jan. 17, 1866.

MEDICAL ET QUETTE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A is sent for to a sick lady: he being from home and not putting in his appearance till the fourth day after being solicited, B (who happened to be in the village) is called in. The following day A visits the house of the sick lady, but is refused an interview. A then addressed a letter to B, apprising him (B) of his (A's) return, and requested that the patient be handed over to him in accordance with the rules of medical etiquette. B, of course, complied, and discontinued his attendance, but on the following day, to the great surprise of B, the patient wrote to him and requested him to visit her again or send more medicine. B, not understanding this anomaly, called again on the lady, and is informed by her that she will not be attended by A (whom she considered had slighted her), and urgently requested B to continue his attendance. B consented. Pray, Sir, 1st, to whom does the patient belong. 2nd, Has B violated the rules of medical etiquette?

By answering the above queries in your next impression you will greatly oblige,—Yours obediently, J. T. J.

[Under the circumstances stated, we think that the patient belongs to B, and that B has not violated the rules of medical etiquette.—ED. MEDICAL PRESS AND CIRCULAR.]

At the meeting of the Court of Examiners of the Royal College of Surgeons of London on the 16th inst., 66 gentlemen presented themselves for examination, 36 for the "primary" and 30 for the "pass," of the former eight candidates were referred back for three months, and of the latter nine were rejected, making a total of seventeen candidates out of sixty-six refused admission, or rather more than one fourth of the whole.

MEDICAL SERVICES IN INDIA.—A commission "to consider and report upon certain points connected with the Indian Medical Service" has been appointed. Mr. J. Strachey, C.S., will be the President; and Dr. H. A. Bruce of Bengal, Dr. F. S. Arnott of Bombay, Dr. W. R. Cornish of Madras, and Lieutenant-Colonel H. K. Burne, of the Bengal Staff Corps, the members.

A CASE of death during the administration of chloroform occurred last week at St. Mary's Hospital in the person of a man who was undergoing the operation of evulsion of the toe nail. It appears from the evidence on the inquest that the usual precautions of stethoscopic examination had been taken, and that no cause for the sudden syncope had been made manifest either by that or the subsequent post mortem examination. It was represented that the man had walked three miles and a half to the hospital that morning, and had expressed an unwillingness to receive an anæsthetic; but these circumstances were properly held to afford of themselves no sufficient reason for the unfortunate result.

BRAHEE SUGAR.

UNDER this curious and attractive title, our contemporary the *Lancet* recently admitted into its pages a puff of what turns out to be apparently sugar of milk. The writer is now stated to be the brother of a well-known homeopathist in Edinburgh, and his letter contained a sufficient amount of wonderful cures to attract a considerable amount of attention. Our druggists have been besieged with inquiries after Brahee, and it has recently had a large sale. The mystery about it has, however, leaked out, and it will need to be something wonderful to keep its position now. Though indeed there is hardly a better field for quackery than rheumatism, for there is no disease more thoroughly uncertain in its behaviour to drugs or remedies, or one which may be more safely entrusted to skilful nursing alone; and if the Brahee or saccharum lactis contain only a moderate proportion of morphia, its success is certain.

If you will permit me I will try to illumine the darkness of your correspondent of last week with respect to the endoscope, which, he states, is unknown in Belfast. The credit of its invention, or at all events of its practical application to disease, was due to Desormeaux, and it has been perfected by Dr. Cruise of Dublin, who has published a most interesting paper containing an account of the instrument, and the results of his most valuable investigations with it. I would commend this paper to the attention of "Darkness," who will see in it the manner of exploring the urethra, examining the character of a stricture, or the alterations of the mucous lining of the canal. To Dr. Cruise the endoscope also affords a means of examining the bladder, and he narrates how Dr. R. McDonnell tested the powers of his instrument by placing in the bladder of a dead person three articles, and then challenging him to tell what they were. In a few minutes Dr. Cruise was able to do so, and informed Dr. McDonnell of the presence in the bladder of a brass screw, a Minié bullet, and a lump of plaster-of-Paris.

With regard to Brahee sugar the rest of the world are in nearly as great darkness as your correspondent. A description of the therapeutical effects of Brahee sugar appeared in the *Lancet* by an anonymous correspondent, in which the writer records some wonderful cures effected by it, but neither giving the dose nor the nature of the medicine. A letter in the last *Lancet* from an apothecary in Leith, who, it appears, dispensed the Brahee, envelopes the matter in greater mystery, for according to him the introducer of the medicine is making arrangements for the sale of the medicine by a wholesale house, and appeared to be reluctant to tell anything about it. The remedy may possibly turn out to be a valuable one, but it is being introduced to the profession in a most questionable way.

MEDICAL NEWS.

CHAIR OF GEOLOGY IN THE EDINBURGH UNIVERSITY.—It has been transpired within the last day or two that the Senatus Academicus have resolved to petition Government to erect a chair of geology, as a compliment to the chair of natural history, so ably filled by Professor Allman.

STATISTICAL AND SOCIAL INQUIRY SOCIETY OF IRELAND.—POSTPONEMENT OF MEETING.—The meeting announced for Tuesday the 23rd is, in consequence of the Friends' Institute being otherwise occupied, postponed till Monday the 29th instant.

SOME interesting official statistics of the wine trade in France have been lately published by the French Government. According to these it appears that the average annual produce of the vineyards in France is 38,000,000 hectolitres. Of this quantity 13,340,000 hectolitres, are offered for sale; 2,454,000 hectolitres are distilled and converted into spirits of wine or brandy; the quantity exported to foreign countries amounts to 2,030,000 hectolitres; 220,000 hectolitres are used for vinegar, and 15,245,000 hectolitres are consumed by the growers or sold direct to consumers. The vineyards, which are in the hands of 2,200,000 landed proprietors, are situated in 78 departments. The annual consumption of wine in Paris by each inhabitant is estimated at one hectolitre and a half. The hectolitre is a little over 22 gallons.

GEORGE H. PORTER, Esq., M.D., F.R.C.S.I., senior surgeon to the Meath Hospital, and County of Dublin Infirmary, has been elected surgeon to Simpson's Hospital in the room of the late Edward Hutton, M.D.

A SLIGO DOCTOR APPOINTED TO THE COMMITTEE ON THE CATTLE PLAGUE.—Some time ago we mentioned in these columns that Dr. Tucker of this town, had produced an able work on "Cholera and Fever, with remarks on the Treatment of Cattle Plague." Dr. Tucker's intimate acquaintance with the latter subject has procured him the honourable appointment of member of the Cattle Plague Committee.

His Excellency the Lord Lieutenant has been pleased to select Dr. Tucker to proceed to London, in company with other gentlemen of eminence in the medical profession, in order to observe and consider the most approved and successful modes of treating the cattle disease, which is producing such devastation on the herds of England and Scotland. While the appointment to such an office confers eminent distinction on Dr. Tucker, we would also consider it as reflecting no small amount of credit on the town which has the benefit of Dr. Tucker's able services. It is gratifying to find that Sligo can produce men of such excellence in their profession as to merit being classed with the ablest professionals in Ireland in an appointment of such honour and importance. In consequence of Dr. Tucker's being selected by the Lord Lieutenant for the above named purpose, an extraordinary meeting of the Sligo Dispensary Committee was held last week, at which Dr. Fausset was appointed to officiate *pro tempore* as medical officer during the absence of Dr. Tucker.—*Sligo Chronicle*.

ACCIDENT TO DR. ALLSHORN, EDINBURGH.—On Thursday evening last a serious collision took place at the St. Margaret Station of the North British Railway, by which several passengers were dangerously hurt, including Dr. Allshorn of Princes-street, who was injured about the head, and is still in a precarious condition from the accident.

THE LATE SIR JOHN MCGREGOR, K.C.B.—This distinguished military surgeon and physician, who died on Saturday last at Ryde, Isle of Wight, at the age of seventy-four, was the second son of Mr. Duncan Macandrew of Culross, county of Perth, and assumed the name of McGregor, instead of his patronymic, in August 1863, the family being descended from the McGregors of Kora, the name having been changed after the rebellion in Scotland in 1745. After his education at the University of Edinburgh, he entered the medical branch of the army as hospital assistant in 1803, and saw considerable service. He became assistant-surgeon, February 15, 1810; regimental-surgeon, April 30, 1822; staff-surgeon, 7, 1846; deputy-inspector-general, October 21, 1853, and was for some years stationed at Madras in that capacity before his retirement. Sir John was made an honorary physician to her Majesty in August 1859, and was, in recognition of his eminent professional services, created a Knight Commander of the Bath the same year.

DR. ALEXANDER IRVINE of Clonmany, county Donegal, has been unanimously elected Medical Officer to the Irwinstown Workhouse and Dispensary, in the room of Dr. G. Irvine, deceased.

RINDERPEST AND SMALL-POX.—With reference to the small-pox theory advanced by Dr. Murchison, we may state that Professor McCall of Glasgow, is at present engaged investigating the matter, and in the meantime is experimenting upon two animals. Both of these animals experimented upon have been attacked and recovered from the plague. The one has been vaccinated, and the other inoculated with virus of small-pox, taken from the human subject. What the result of this interesting experiment may be we cannot at present tell, but we have no doubt Professor McCall will make it known as soon as completed.

THE PRITCHARD CASE AGAIN.—We are informed on reliable authority that this case will soon assume a new phase. Dr. James Paterson of Glasgow, whose conduct was so severely censured by the Lord Justice Clerk at the trial, has raised an action of damages against the *Glasgow Morning Journal* for a letter which appeared in its columns. The Lord Advocate and Mr. Gifford are retained for the defence.—*Fifehire Journal*.

GLASGOW EYE INFIRMARY.—The annual general meeting of the qualified contributors and subscribers to the Glasgow Eye Infirmary was held on Thursday afternoon, in the Religious Institution Rooms—Mr. Robert Daighish, M.P., for the city, presiding. The forty-second annual report of the directors was submitted, showing that during last year there were 1962 new cases admitted, which, with 1894 remaining on the roll at the date of last report, gave a total number of 3856 cases treated, showing that the increase in the number of cases noticed for many years past was continuous and progressive. The treasurer's accounts showed that the amount on the side of revenue was £1791 4s. 8d. After deducting the various items of expenditure, including £177 13s. 6d for painting and repairs, there was cash in bank to the amount of £270, and on hand 12s. 4d. The report was adopted. ■

MEDICAL DIARY OF THE WEEK.

WEDNESDAY, JAN. 24.

MIDDLESEX HOSPITAL.—Operations, 1 p.m.
 ST. MARY'S HOSPITAL.—Operations, 1½ p.m.
 ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ p.m.
 ST. THOMAS'S HOSPITAL.—Operations, 1½ p.m.
 GREAT NORTHERN HOSPITAL.—Operations, 2 p.m.
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 p.m.
 LONDON HOSPITAL.—Operations, 2 p.m.
 HUNTERIAN SOCIETY.—7 p.m. Special Council.—8 p.m. Dr. Peacock, "On some of the Hospitals in the North of Europe, and on Hospital Construction."—Mr. Couper, "On a Case of Deficiency of the External Ear remedied by Operation."

THURSDAY, JAN. 27.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 1 p.m.
 ST. GEORGE'S HOSPITAL.—Operations, 1 p.m.
 LONDON SURGICAL HOME.—Operations, 2 p.m.
 WEST LONDON HOSPITAL.—Operations, 2 p.m.
 ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 p.m.
 ROYAL INSTITUTION.—3 p.m. Professor Tyndall, "On Heat."
 KING'S COLLEGE MEDICAL SOCIETY.—8 p.m. Mr. Welch, "On Ovarian Cysts."

FRIDAY, JAN. 26.

WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ p.m.
 ROYAL INSTITUTION.—8 p.m. Mr S.W. Baker, "On the Sources of the Nile."

SATURDAY, JAN. 27.

ST. THOMAS'S HOSPITAL.—Operations, 9½ p.m.
 ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ p.m.
 KING'S COLLEGE HOSPITAL.—Operations, 1½ p.m.
 ROYAL FREE HOSPITAL.—Operations, 1½ p.m.
 CHARGING-CROSS HOSPITAL.—Operations, 2 p.m.
 ROYAL INSTITUTION.—3 p.m. Prof. Westmacott, "On Art Education."

TO CORRESPONDENTS.

Dr. Edwards Crisp's communication has been received.
 Mr. Griffin's letter is inserted.
 Dr. Edwin Hearne.—The communication has been received, and we hope that the health of our esteemed Correspondent will be improved by his temporary change of residence.
 MR. HARRY LEACH is thanked for his courteous communication, and we shall be happy to receive any further information on the subject.
 MR. W. J. GOODWIN AND ST. GEORGE'S HOSPITAL.—The subject does not appear to us to be of sufficient public importance to justify us in reprinting the letter, but if Mr. Goodwin will write a letter to ourselves, embodying in a brief space his cause of complaint against the authorities of the Hospital, we will give it our best attention.

MEDICAL VACANCIES.

ENGLAND.

Morpeth Dispensary—Resident Medical Officer.
 Southampton—Officer of Health.
 Officer of Health for Southampton. Not to practice. Salary £150. Application to be made before the 5th of February.
 Liverpool Natter Hospital—House Surgeon. Salary £50. If Junior House Surgeon be elected, his appointment (£60) will be filled up. Election January 26th.
 London Fever Hospital—Assistant Medical Officer. Salary £9 per month with residence—Election January 25th.
 Morpeth Dispensary—Resident Medical Officer. Salary £90, with fuel and residence. Election, February 4th.
 Bridgewater Union—Medical Officer. Salary £43, and fees.—Election, 31st inst.
 Broadmoor Criminal Lunatic Asylum—Assistant Medical Officer. Salary £175, increasing to £200, with fuel, residence, and attendance. Election February 1st.

IRELAND.

Carrickmacross Union—Donaghmore Dispensary. Salary £70. Election 26th inst.
 Letterkenny Union Workhouse.—Vice Dr. Grueber, deceased. Salary £50. Election 26th inst.
 ENNISKILLEN UNION, TEMPO DISPENSARY, vice Dr. Grattan, resigned. Election, January 27th. Salary £50, exclusive of fees. Population 9076. Acreage 30,911.
 CLONMANY DISPENSARY, INNISROWEN UNION.—Salary £90, with Registration and Vaccination Fees. Election, Tuesday, the 16th. Population 5,780; acreage, 23,375.
 BAKAHER DISPENSARY, PARSONSTOWN UNION.—Vice Dr. Tarleton. Salary, £100 a year, exclusive of fees. Election, Friday, 2nd inst. Population, 10,395; acreage, 39,961.

MEDICAL APPOINTMENTS.

A. D. Anderson, M.D., has been nominated a Director of the Glasgow Royal Lunatic Asylum by the Faculty of Physicians and Surgeons Glasgow.
 Mr. J. Barlow, of Wem, has been elected Dispenser to the Salop Infirmary, Shrewsbury, vice Mr. W. Edwards, resigned.
 T. Blades, L.R.C.P. Ed., has been elected Medical Officer and Public Vaccinator for the Morland District of the West Ward Union, Westmorland, vice J. M. Pothergill, M.D., resigned.
 A. Canton, M.R.C.S.E., L.D.S.R.C.S., has been appointed Assistant Dental Surgeon to the Dental Hospital of London, Soho-square, vice W. F. Forsyth, L.D.S.R.C.S., resigned.
 C. Evans, M.D., Assistant-Physician to King's College Hospital, has been appointed Pathological Registrar of that institution.
 E. F. Fussell, M.B., M.R.C.P. has been appointed Treasurer to the Brighton Lying-in Institution.
 Dr. G. de Gor. Griffith, Physician to the Pimlico and Westminster Institute for Diseases peculiar to Women and Children, has been elected Physician-Accoucheur to St. Saviour's Maternity Charity.

E. Gwynn, M.D., has been appointed Surgeon to the Holloway and Islington Dispensary, vice Dr. Benson, resigned.
 J. Harrison, M.R.C.S.E., has been appointed Medical Officer for the Braintree District of the Braintree Union, Essex.
 W. Hoffmeister, M.D., M.R.C.S., has been elected one of the Surgeons to the Cowes Dispensary.
 W. L. Hopkinson, M.D., has been appointed Consulting Physician to the Stamford and Rutland Infirmary, on resigning the Honorary Physiciancy.
 P. A. Jackson, M.R.C.S.E., has been appointed Medical Officer for District No. 2 of the Billesdon Union, Leicestershire, vice J. Hunt, M.R.C.S.E., resigned.
 W. Newman, M.D., M.R.C.S., has been appointed Surgeon to the Stamford and Rutland Infirmary.
 C. F. Oxley, L.R.C.P. Ed., has been appointed Resident House-Physician to the Westminster Hospital, vice C. St. Aubyn Hawken, M.R.C.S.E., whose appointment has expired.
 J. M. Pagan, M.D., has been re-elected a Director of the Glasgow Royal Lunatic Asylum.
 T.H. Redwood, L.R.C.P.L., has been appointed Senior Assistant-Surgeon to the Rhymney Iron Works, Monmouthshire, vice T. Damant, L.R.C.S. Ed., appointed Medical Officer for District No. 3 of the Aylsham Union, Norfolk.
 W. Rivington, F.R.C.S.E., Assistant-Surgeon London Hospital, has been elected Surgeon to the London Dispensary, Church-street, Spitalfields, vice T. B. Curling, F.R.C.S.E., resigned.
 O. B. Shore, M.D., M.R.C.P.L., has been appointed Physician to the Stamford and Rutland Infirmary, vice W. L. Hopkinson, M.D., M.R.C.P.L., resigned.
 T. Skinner, M.D., has been appointed one of the Medical Officers to the Lying-in Hospital, Liverpool.
 Arthur B. Steele, M.R.C.S.E., has been appointed Lecturer on Midwifery and the Diseases of Women in the Liverpool Royal Infirmary School of Medicine.
 T. Taylor, M.R.C.S.E., has been appointed Medical Officer for the Bocking District of the Braintree Union, Essex.
 Mr. T. A. Turner, has been appointed House-Surgeon to the Royal Westminster Ophthalmic Hospital, King William-street, Strand, vice J.G. Mackinlay, L.R.C.P.L., appointed Resident Medical Officer to the Charing-cross Hospital.
 J. Clarke, L.K.Q.C.P.I., has been appointed Surgeon to the Constabulary, Ballieborough, Co. Cavan, vice J. Taylor, L.F.P. & S. Glas., deceased.
 Geo. Hatchell, M.D., has been admitted a Member of the Royal Irish Academy.
 W. Lyon, M.D., has been nominated a Director of the Glasgow Royal Lunatic Asylum by the Faculty of Physicians and Surgeons, Glasgow.

BIRTHS.

January 2nd, at Kiltegan, the wife of Dr. Dockeray, of a daughter.
 At 5, Mansion-House Road, Grange, on the 5th instant, the wife of Dr. Norman Bethune, F.R.C.S.E., of a daughter.
 At 1, Woodside Crescent, Glasgow, on the 5th inst., the wife of Dr. M. Call Anderson, of a daughter.
 December 30, at Perth, the wife of Assistant-Surgeon G. S. Davie, M.D., Royal Artillery, of a daughter.
 Janua 7, at Rathkeale, the wife of Assistant-Surgeon R. A. Alleyne, Bombay Medical Service, of a daughter.
 January 7, at Tralee, the wife of R. Fitzmaurice, Esq., M.D., of a son.
 At Calder Bank, Mid-Caldor, on the 11th inst., the wife of Walter Watson, M.D., of a son.

MARRIAGES.

January 4, in Drumconrath Church, by the Rev. Richard K. Bolton, A.M., Incumbent of Newbold-sum-Dunstan, Derbyshire, William Fleming, Esq., 95th Regiment, son of C. Fleming, Esq., M.D., Merriown-quare, to Jane Marion, daughter of the Rev. Lyndon H. Bolton, A.M., Rector of Drumconrath, county Meath.
 December 30, at Rathlimes Church, Edmund Cooke Nicholson, Esq., I.D., to Annie Elizabeth Victoria, eldest daughter of the late James Joffit, Esq., M.D., first-class Staff-Surgeon, and grand-daughter of the late Major Sweeney, 70th Regiment.
 January 3, at St. Mary's Church, Newry, by the Very Rev. the Dean of Dromore, A. Walker Sinclair, Esq., Newry, to Mary Margaret, second daughter of W. A. Davis, Esq., M.D., Newry.
 At Windmill Hill House, Dalziel, Lanarkshire, on the 8th inst., by the Rev. Joseph Loudon, William Whamond, M.D., Jarrow, Durham, to Mary Ann, eldest daughter of Mr. Thomas King.
 At Broxburn Hall, on the 2nd inst., by the Rev. William White, Knox's Free Church, Haddington, father of the Bridegroom, Dr. Peter White, Fenwick, to Jeanie, eldest daughter of the late Joseph Alexander, Esq., Broxburn Hall, Lullithgowshire.
 At 22 Royal Terrace, Edinburgh, on the 11th inst., by the Rev. James Grant, D.C.L., Oxon, D.D., George Dods, Esq., M.D., Hong-Kong, to Faggie, daughter of John Crabbe, Esq.
 At 4 Bonnington-place, on the 11th inst., by the Rev. James Grant, D.C.L., Oxon, of St. Mary's, Edinburgh, John Gavin, Esq., of Tankow, China, to Mary Scott, only daughter of George Walker, Esq., I.D.
 At the residence of the bride's sister (137, Princes-street, Edinburgh), on the 4th inst., by the Rev. Dr. Candlish, of Free St. George's, James J. Hardy, Esq., surgeon, Banchory Terman, Kincardineshire, to Jane Kerr, second surviving daughter of the late Francis Adams, Esq., M.D., I.D., of Banchory.
 At Kihlold, on the 9th inst., by the Rev. Lachlan Maclean, Airsaig, Inaich MacCallum, Esq., surgeon, to Margaret Cowie, relict of Charles MacLeod, Esq., of Scotas, Invernesshire.

DEATHS.

Jan. 17, at Kiltegan, of puerperal fever, Agnes Henderson, wife of Dr. Dockeray.
 Jan. 10, at his residence, 9 Kildare-street, George Davis, Esq., M.D., deeply regretted.
 Jan. 14, at Mountjoy-square, James Richard Dunne, Esq., J.P., A.M., C.S.I., Moymore, county Clare, sincerely and deservedly regretted.
 At 62 Queen-street, Edinburgh, on the 14th inst., David James Simpson, M.D., aged 24, eldest son of Professor J. Y. Simpson.

"SALUS POPULI SUPREMA LEX."

Original Communications.

SOME REMARKS ON THE VALUE OF LARYNGOSCOPY:

BEING A REPLY TO DR. MORELL MACKENZIE.

By EBEN. WATSON, M.A. & M.D.,

LECTURER ON PHYSIOLOGY IN ANDERSON'S UNIVERSITY, GLASGOW.

It is annoying to most persons to be misrepresented, whether it be done wilfully or through misunderstanding, and in so far I have felt annoyed by Dr. Morell Mackenzie's remarks made on my papers in his recent communication to THE MEDICAL PRESS AND CIRCULAR for 10th January, 1866. Had this matter merely concerned himself and me, had it only involved Dr. M. Mackenzie's holding a poor opinion of me and my writings, I should not much have troubled myself to reply; but justice to my own professional character seems to me to make a reply from me necessary, and that all the more because Dr. M. Mackenzie has attacked, in THE MEDICAL PRESS AND CIRCULAR, papers of mine published in the *Lancet* (June 3rd and July 1st, 1865). This was not the proper course for him to take, because the readers of the two periodicals may be different, and thus the matter in dispute could not be fairly laid before them. I waive this point, however, and merely refer to the *Lancet* where the original papers may be found.

For the sake of brevity I shall pass by Dr. Morell Mackenzie's introductory observations about "vested rights," though I really do not perceive their relevancy to the matter in hand.

I cannot but remark, however, that the contrast he draws between himself and me is very amusing. I am the type of pre-laryngoscopic darkness, he the apostle of modern illumination. My book "was useful and instructive" enough in pre-laryngoscopic times; his papers, we are led to infer, are the very concentrations of all that is recent and reliable. Now, really, this is too bad. It is in bad enough taste to write thus regarding me, but it is infinitely worse regarding Cheyne, Porter, Ryland, Trousseau and Beloc, Horace Green, and others who have written so ably on the larynx before Dr. Morell Mackenzie studied medicine at all. What! is pathology old fashioned; is there no good in descriptions of disease, or of the means of diagnosis founded on it and them? Is there nothing to be learnt from the practice of others and the *rationale* of their treatment, and is that treatment likewise become obsolete? I hope not, else we have bid farewell to the scientific surgery of the larynx.

I shall perhaps be excused for stating here, that exactly ten years before Dr. Morell Mackenzie became acquainted with laryngoscopy through the teaching of Czermak—viz., in the year 1849—I wrote and printed, as it was then the custom to do, an essay on the larynx as my inaugural thesis when I became Fellow of the Faculty of Physicians and Surgeons of Glasgow, and in it I mentioned that I had already performed some experiments towards obtaining a laryngoscope, the idea of which I owed to the often quoted passage in Liston's "Practical Surgery." I have still in my possession one of these rude laryngoscopes, and I did not know till lately that it was almost identical with Bozzini's; but I was soon discouraged by the difficulties of applying such imperfect instruments, and gave up the investigation at that time; yet I do not doubt that this early, though unsuccessful trial, gave me some advan-

tage when I recommenced the study in more favourable circumstances, and prepared the way for my making more rapid progress in the art of laryngoscopy than I should otherwise have done. My experience in its application to diagnosis, both in cases occurring in my own practice and in those sent to me by other practitioners, is now considerable, and my faith in its results is very great; so that Dr. Mackenzie's attack was the less expected by me, for though I had been guilty of some opposition to his dogmata, I was not aware till I had read this paper of his, that I could possibly be accused of having written anything which might justly be deemed antagonistic to laryngoscopy; but we shall see.

I believe the best way of dealing with such statements as those of Dr. Morell Mackenzie is just to give the very words—first those which he attributes to me, and then in immediate sequence those which appear in the *Lancet*. Thus, Dr. Morell Mackenzie declares that I have "implied that laryngoscopy was almost superfluous in diagnosis and certainly useless in practice." (MEDICAL PRESS AND CIRCULAR, p. 23.) Whereas my words are, "the application of the laryngoscope to the investigation of the diseases of the larynx is a very welcome addition to our means of diagnosis. It gives us another and an entirely new source of evidence to judge from, and it is therefore fitted to make our opinions more correct and our treatment more definite than heretofore."—*Lancet* for 1865, p. 5.

Much more might be quoted from my paper in the *Lancet* to the same effect as that of the above passage; and I really think that words could hardly be chosen which would express a fuller appreciation of laryngoscopy. The only real difference between Dr. Morell Mackenzie and myself on the subject is just this—How does laryngoscopy improve practice? I answer that it does so by improving diagnosis; for whatever makes diagnosis more accurate renders treatment at the same time more precise, and therefore more successful. He, on the other hand, believes that the laryngoscope gives a new facility for topical applications to the larynx. In this I cannot agree with him. I have not found it so, and I think he has shown in his own records of his operations on the larynx that he has not been guided in them either surely or safely by the laryngoscope. I think no one but a very enthusiastic laryngoscopist would expect that it could be otherwise, since "the operator has to manage the forceps (or whatever instrument is required) with his right hand, while he holds the mirror with his left in the fauces of the patient, and the part operated on is out of the range of his direct vision and only presented to him in the reverse picture reflected by a half-inch mirror."—*Lancet* for 1865, p. 8.

For the ordinary application of solutions to the interior of the larynx there is no guide in my opinion like the index finger of the left hand, which can easily be made to touch the tip of the epiglottis, and then the sponge probang may be surely and safely passed along the finger-nail and down the laryngeal surface of the epiglottis to the rima. An extensive experience of this proceeding for the last sixteen years enables me to recommend it with confidence.

Dr. Morell Mackenzie tries to ridicule my method of using the laryngoscope, and, perhaps, in attempting brevity and writing of little things which had become very familiar, I did not make myself sufficiently plain. It is quite evident that Dr. Morell Mackenzie does not understand my method, for it is not essentially different from Czermak's, which he, I believe, also follows. In my paper I stated that I had sometimes obtained a view of the glottis by direct light, and I remarked in passing that a range of houses opposite my consulting-room windows reflected the light pretty strongly into them when the sun was shining brightly. I surely need not tell Dr. Morell Mackenzie that plate glass windows do reflect the sun's rays, and that this occurrence is fitted to make the light apparently coming directly through my consulting-room windows better suited for laryngoscopy than it otherwise would be. This is all I meant by noticing the fact which, however, I never thought would be subjected

to a hostile criticism, else I should have been fuller in my statement, or perhaps I should not have made it at all; for there is no doubt that the perforated mirror is required in far the greater number of cases.

I can offer no apology for my dulness in not perceiving the advantages of many little inventions of Dr. Morell Mackenzie's to assist (?) laryngoscopists. I refer to his "light concentrator," his "epiglottis pinicette," his "head rest," or his very barbarous looking "self holder or fixateur." I believe that all these things are very unnecessary, to use the very mildest term.

Again, Dr. Mackenzie quotes from my briefly-stated conclusions, given at the end of my paper, "that the special office of the laryngoscope is to give negative evidence—i.e., to show what is not the state of the larynx," and there he stops, as if that were all I had written on the point, whereas had he quoted the very next conclusion, the whole aspect of the affair would have been changed; for, just in the next line may be read, "but in some cases, such as ulcers, tumours, &c., it (the laryngoscope) does give positive information, which could not be otherwise obtained." I need make no remark upon this, except that Dr. Morell Mackenzie has here once more represented me not quite fairly.

My intention in mentioning separately these two parts of the assistance given by laryngoscopy in diagnosis was to express how very great that assistance was in that large class of cases in which the symptoms, and perhaps even some of the physical signs, are ambiguous, or at least not quite clear, as to the presence of ulcers, tumours, &c.; not by any means to depreciate the positive information yielded by it where these visible alterations are actually present in the larynx.

And now, perhaps, I might leave without any answer the sweeping accusation of Dr. Morell Mackenzie, that I have "entered the lists in favour of exploded views." I dare say the readers of THE MEDICAL PRESS AND CIRCULAR will think that I have just exploded some of Dr. Morell Mackenzie's views, and if thereby I induce him to be fairer and more charitable in future to his fellow-labourers in the field of applied science, I shall not regret what I have done. But, in reality, it matters very little what either of us has written on such a subject as this. I profess myself to be learning in it every day, and I hope that Dr. Morell Mackenzie is not too good or great a laryngoscopist to improve yet by his daily experience. Whenever I am convinced of error I shall change my views of this or any other subject, not for a moment deterred by what I may have previously written.

If I can at all regard the matter at issue between Dr. Morell Mackenzie and myself in a dispassionate spirit, there is one point in it regarding the value of laryngoscopy which certainly deserves the serious attention of the profession, and it is this: are we warranted in casting aside as useless, antiquated, exploded, in laryngeal cases, the older methods of diagnosis, now that we have learned a new one? Does laryngoscopy supersede all the other sources of information to which we had recourse a few years ago, or does it only assist in the conclusion arrived at on consideration of the whole evidence? The latter is my own opinion. I believe that laryngoscopy is to be ranked with stethoscopy and feeling with the finger as the three chief methods of physical diagnosis; and while no doubt men will differ as to their relative values, yet I dare say the majority will agree with me that no diagnosis can be scientific or well founded unless all the three methods have been carefully practised and compared. It should likewise be remembered that there are many cases in which laryngoscopy cannot be satisfactorily practised, but on this I shall not at present dwell.

I hope that I have now shown to the satisfaction of most readers of THE MEDICAL PRESS AND CIRCULAR that my views are not so "exploded" as Dr. Morell Mackenzie would have had them to think, but I can hardly flatter myself that I shall have succeeded in bringing him to that opinion. I have, however, reserved one

statement for the end of my paper which I hope will be somewhat more satisfactory, if not even conciliatory, in his estimation. It is that, although I have not been able to approve of many of his newly-invented instruments, yet I am happy to say there is one exception, and that is in the case of his laryngeal galvanizer. Dr. Morell Mackenzie has mistaken what I stated regarding this instrument in my former paper. I did not describe it as innocent but very inefficient, for I had never even seen it at that time. My words, as he will find by looking again at the *Lancet* for July 1st, 1865, p. 7, are, "I think it—the galvanizer—likely to be innocent but very inefficient;" and why did I think so? For the reason immediately added in the words, "as indeed the application of galvanism in medicine has generally proved to be." Now, however, that I have obtained this laryngeal galvanizer, I can and do describe it as a very pretty and ingenious instrument, and one which admirably performs the office it is intended for—viz., to pass electric currents through the glottis. I have as yet employed the laryngeal galvanizer in only two cases, and these are still under treatment, so that it would be premature at present for me to speak of the ultimate efficiency of electricity when applied directly to the organ of voice. I intend, however, to report my cases faithfully in due time, but even from what I have already seen of this topical application, I am sanguine enough to expect that the report will be favourable, and I shall be most happy if this proves an exception to my general experience of the medical use of electricity.

2, Newton-terrace, Glasgow, 20th Jan., 1866.

ON A

NEW METHOD OF APPLYING REMEDIAL AGENTS TO THE CAVITY OF THE TYMPANUM.

By EDWARD BISHOP, M.D., M.R.C.S.E., &c.,

SURGEON TO THE METROPOLITAN INFIRMARY FOR DISEASES OF THE EAR, SACKVILLE-STREET, LONDON.

(Continued from page 10.)

In reporting the cases selected for treatment by means of pulverized fluids and catheterism at the Metropolitan Infirmary for Diseases of the Ear, Sackville-street, I have not included those attended with considerable disorganization, cases, I may add, frequently met with in hospital practice, a large proportion of which might have been cured by timely treatment; but it is only right to state, in some of these, of a very unpromising character, considerable relief has been afforded, several at present under treatment showing daily symptoms of improvement.

The kind of cases likely to receive the greatest benefit are those attended with closure of the Eustachian canal, either at its faucial or tympanic extremity or its entire length. This closure may be the result of inflammation and thickening of the mucous membrane, commencing in the fauces and extending up the tube, or it may be the result of inflammation commencing in the tympanic cavity, from cold, fever, or other exciting cause, very frequently observed in children.

Practically, in these cases it is found that, associated with obstruction of the Eustachian canal, there is either a dry condition of the lining membrane of the tympanic cavity or the secretion is too abundant, producing in each case, singular as it may appear, the same distressing *tinnitus*, and this quite out of all proportion to the deafness existing at the time. When *tinnitus* can reasonably be referred to disease of the middle ear and its appendages, it may generally be attributed to pressure, for where the secretion is too abundant and the natural outlet closed or contracted, the cavity of the tympanum is filled, the ossicula and the contents of the middle ear are compressed, and, as the membrana tympani is very unyielding, the stapes is driven against the inner membrane, and pressure is produced upon the fluid in the cavities of the internal

ear, and is felt by the delicate expansion of the auditory nerve.

Other structures also are involved, but I must not encroach too much on your valuable space.

The fact, however, is illustrated by the immediate cessation of tinnitus, when, in acute abscess of the middle ear, the membrane ruptures, and the pressure is suddenly removed.

In cases where there is a mere closure of the Eustachian canal, attended or not by a dry condition of the mucous membrane, tinnitus often exists, but the pressure is produced in a different way. The Eustachian canal is not only intended as an outlet for the natural secretion, but for the entrance of atmospheric air. When, therefore, the latter is excluded by closure of the passage, there is not sufficient resistance to the pressure of the external atmosphere, and the membrana tympani is forced inwards. The contents of the cavity are gradually compressed, the ossicula being pressed against the opposite wall of the tympanum.

It is an *interesting* as well as important fact that so many cases of deafness are caused by disease of the mucous membrane, and it is in these, I believe, the use of pulverized fluids will be found valuable.

Case 1.—W. P., at 37, a waterman, admitted October 17th, 1865, a robust, healthy looking man, much exposed to the weather, complains of frequent cold in the head, totally deaf, as he expresses it, of the right ear, and gradually becoming so of the left. Lost the hearing on the right side fifteen years since after an attack of small-pox, when he had violent pain for three or four days, followed by copious discharge of matter. After this he became gradually deaf on this side, and at present can only hear very loud noises close to the ear. He can, however, faintly perceive the ticking of a loud watch over the mastoid process; the external meatus dry and devoid of wax, the surface of the membrana tympani desquamating, and there is the mark of an old cicatrix in a line with the handle of the malleus. An exostosis at the point of junction between the membrane and the meatus is apparent, and the whole membrane is very concave. Valsalva's method of forcing air into the tympanum produces no effect, nor does the more potent one of Politzer answer any better. The attempt, also, to introduce the Eustachian catheter failed, so that so far as this ear was concerned, the case appeared very unpromising.

On the other side, the *left*, the deafness was less complete, but, gradually getting worse, the watch could be heard only when in contact with the ear, but there was continual and distressing tinnitus. The mucous membrane of the fauces was congested and irritable, the tonsils slightly swollen, and the nasal passages obstructed, the patient breathing continually with the mouth open. On this side both Valsalva's and Politzer's methods of insufflation were successful, and the Eustachian catheter passed easily, the cavity of the tympanum being readily inflated through it, a part of the operation of much importance, if it be not essential to its completion.

Auscultation of this ear detected increased secretion.

Diagnosis on the *right* side, obstruction probably the entire length of the Eustachian canal, cicatrization and general thickening of the membrana tympani, and probably adhesions within the cavity of the tympanum.

On the *left*, closure of the Eustachian canal at its faucial extremity, with relaxed and unhealthy condition of the lining membrane of the tympanic cavity, with accumulation of mucus.

Treatment.—This at first was confined to the left ear, and consisted in the application of a solution of nitrate of silver, twenty grains to the ounce of distilled water several times to the fauces—the passage of a Eustachian catheter made by Weiss and Son, a drawing of which appears at the end of this paper, so constructed as to transmit pulverized fluid into the tympanum, *via* the Eustachian tube. The fluid for pulverization in this case was solution of nitrate of silver, two grains to the ounce. The operation

was performed daily for ten or twelve days, and nothing has been done for three weeks. His hearing on this side is much improved; he says he can "hear quite well enough." The watch he hears readily at the distance of two yards. The tinnitus was relieved after the third and fourth operation; it then gradually disappeared, and he has not had it since.

During the attendance of this patient at the hospital I made several attempts to blow air into the cavity of the tympanum on the right side by Politzer's method, but failed. I then tried my pulverizer, and eventually succeeded in opening the passage. The improvement in this ear was soon so manifest as to encourage me to go on with the case at a future time, his present employment preventing his further attendance. I may add that I consider the condition of the tympanic cavity, on the right side in this case, totally different from the left, that there was too little natural secretion, and that I shall hereafter succeed more effectually in restoring the ear to a healthier state by injecting pulverized alkaline fluid—a method I am adopting with marked success. It seems singular that conditions so essentially dissimilar should be found to coexist in the same patient. It is probably explicable by the fact that the mucous membrane of the Eustachian canal and tympanum on the right side were completely cut off by the closure of the former from the morbid action which had been going on for some time in the fauces.

Case 2.—C. V., æt. 35, a dressmaker and milliner, admitted October 17, 1865, pale and delicate-looking, of strumous constitution; complains of gradually increasing deafness of both ears, with intolerable tinnitus and occasional deep-seated pain; has frequent coryza and has suffered several times from hay fever.

Says she is seldom free from what she terms "cold in the head."

The fauces highly inflamed and deglutition painful, each meatus auditorius somewhat swollen, and the whole organ so painful as scarcely to admit of examination; hearing distance one inch from left ear; right ear in contact only.

Prescribed, one leech to each ear, to be followed by poultices, and to take a warm aperient mixture.

October 19th: Pain and inflammation much relieved, throat also improved and deglutition easier, but the tinnitus more distressing than ever. More careful examination could now be made; the left membrana tympani showed considerable inflammation still going on, the right was dry and collapsed, permitting the projecting malleus to be distinctly seen.

Passed the Eustachian catheter on this side, with immediate relief to the tinnitus and improvement in the hearing, the patient remarking, "I can hear so well at this moment that I am quite confused." This improvement of course passed away during the day, and the ear gradually relapsed into its former condition. Prescribed another leech to the left ear; to take mist. ferri co., with decoct. aloes co.

23rd: All active symptoms abated; the tinnitus almost gone from left ear, but continues the same in the right; passed the catheter on both sides, and very cautiously inflated the tympanum. Some improvement of hearing followed immediately on this operation being completed; to continue the mixture.

25th: Tinnitus nearly gone from both ears; hearing distance three inches from left ear, seven inches from right. Auscultation reveals a dry condition of tympanic cavity; blew pulverized lotion of liq. potassæ into the cavity of the tympanum.

This operation was repeated daily for eight or nine days, when the patient was requested to absent herself for a fortnight; she could now hear the tick of a watch fourteen inches from the left ear, and three feet from the right; she was requested to make use of Valsalva's experiment, once at least daily during her absence. It is scarcely necessary to remind your readers that this consists simply in closing the mouth and nostrils and attempt-

ing a forced expiration, by which air is driven into the middle ear, and the patency of the Eustachian passages secured after they have been once opened by the catheter. This experiment is as old as the hills, as every schoolboy knows, though it is to Valsalva we are indebted for its use as a means of diagnosis.

Nov. 7th: Reports herself as *hearing perfectly*. This, however, is not quite correct, as there is still a marked difference between the two ears. The left, which suffered more from inflammation than the right, has not improved as much as the latter, with which she can hear the tick of the watch three or four yards distance.

Injected pulverized solution of liq. potassæ into each ear, and repeated the operation every other day for twelve days, at the expiration of which period the tinnitus had quite gone, and the hearing distance was daily improving.

Dec. 12th: Hearing distance: left ear nearly three

feet; right, four yards nearly; discharged; reminded not to abandon the occasional insufflation of the ears as before directed.

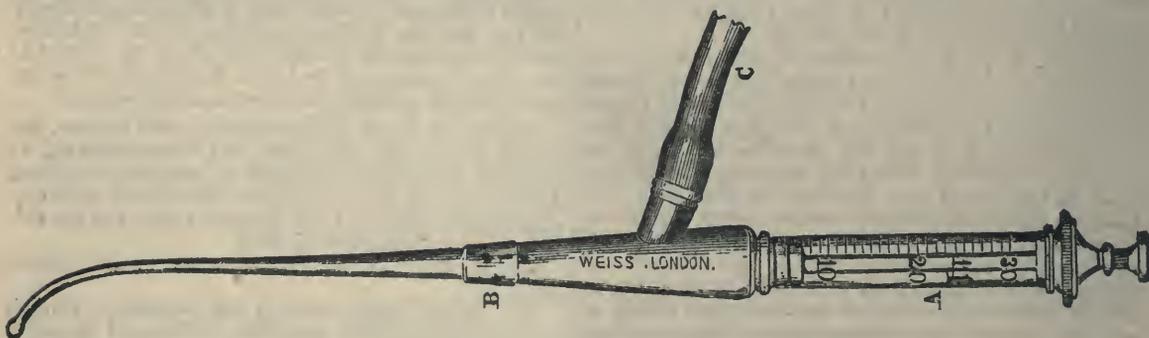

I may observe that in this case the Schneiderian membrane was implicated. This is of frequent occurrence, and to that I applied the pulverized lotion thereto, as well as to the mucous membrane of the fauces.

I have now supplied her with Yearsley's elastic tube and bottle, by means of which she will be able to secure a patent condition of the nasal passages, and to inject a stream of water into the fauces—a method of treatment found highly serviceable, enabling the patient to breathe more freely through the natural passages, the water acting as a tonic to the mucous membrane.

31, Sackville-street, London.

(To be continued.)

I offer no apology for the republication of the illustration which was appended to my former communication, inasmuch as an acquaintance with its mechanism is essential to the comprehension of the line of treatment which I have advocated.

ON THE USES OF THE BROMIDES.

By Dr. G. de GORREQUER GRIFFITH,

PHYSICIAN TO THE PIMLICO AND WESTMINSTER INSTITUTE
FOR DISEASES PECULIAR TO WOMEN AND CHILDREN; PHYSICIAN
ACCOCHEUR TO THE ST. SAVIOUR'S MATERNITY.

THE BROMIDE IN IRRITABLE OVARIES AND OVARIAN COUGH.

THE intimate relationship which exists between the uterus and the lungs has long been known, and the treatment of certain *apparent* lung affections, by acting directly upon the uterus, instead of upon the lungs—leaving these latter organs to be acted on indirectly by treatment—has in many instances proved the value of the knowledge of this relationship.

The papers of Dr. Henry Bennett on the relation of ulceration of the os to pulmonary phthisis are now well known to the profession, and his remarks as to treatment cannot but be corroborated by every practitioner.

The following interesting case came under my notice at "The Institute," where I saw it in conjunction with my colleague, Dr. Bates. The patient is thirty-two years of age, of dark complexion, of the bilio-nervous temperament, much above the middle stature, of spare habit, and masculine build. She is affected with that peculiar blinking of the eyelids, and irregular action of the muscles of the face, which show how nervous she is, and how much the nervous element predominates. At times she is much distressed by "flushes of heat, which seem to run all over her from her head to her very feet, and crimson her face;" then, to these succeed "cold chills," which make her shiver. She is subject to hysterical attacks. These are the most marked nervous symptoms which obtain.

On making an abdominal examination, the abdomen was found to be loose and pendulous. There was considerable pain produced, where pressure was made in the situation of the ovaries, but of that peculiar nature which made the patient laugh (hysterically) when the pressure

was so exercised; moreover, the moment it was made, a fit of coughing was induced, which continued while the pressure was being made, and ceased with the cessation of the compression.

This—the ovarian cough—was very remarkable. It was dry, barking, and spasmodic; it occurred to her frequently both by day and night, not being called into play by any apparent outward circumstances.

The round ligaments were much enlarged and thickened, and rolled under the fingers like swollen, tender cords.

Vaginal examination demonstrated the vagina to be exalted as to its sensibility; enlargement of both ovaries, but more particularly of the right gland; extreme tenderness of both ovaries; thickening of the fallopian tubes attended by an exaltation of sensibility.

Here, also, pressure on either ovary, but particularly on the right, at once induced cough, which ceased almost the very moment the compression was removed.

The patient was placed upon the bromide in gr. x. every two hours. The cough, which before harassed her night and day, quickly left her; her capricious appetite grew better and more natural; her complexion improved and grew fresher, and the hysterical symptoms disappeared. The ovarian neuralgia with which she had been troubled quite left her, nor was there any longer the tenderness on abdominal pressure, or when an examination was made by the vagina.

Of urgent symptoms this is a most decided case of the cure; and should the symptoms at any time recur we have in our hands the power to wield the same powerful remedial agent as we at first employed.

INDIAN CINCHONA BARK.—Dr. M'Iver has analyzed the cinchona bark grown in India, and does not appear to report very favourably of its percentage of quinine. He recommends the medical profession to try the effects of cinchonidine, an alkaloid largely present in the Indian specimens.

ON THE TREATMENT OF SYPHILIS.

By J. L. MILTON,

SURGEON TO ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

(Continued from page 28.)

If after the lapse of a few days the base of the ulcer still remain covered with a tenacious secretion, or if the ulcer itself threaten to spread, the soda has not been used freely enough, and it will be as well to apply it again, but very gently, and only to those parts which appear unhealthy. Any further resort to it is rarely requisite in the milder forms of chancre, but the more obstinate cases may demand four or five applications. When the sore has become stationary and has begun to contract, and when there is a pale, delicate, blue cuticle extending inwards from the edge, the caustic is no longer requisite, and zinc ointment may now be substituted for any lotions, particularly at night. Should the base shoot above the level of the skin, an escharotic may be used. The sulphate of copper is, perhaps, as good as anything yet tried.

It is the fashion to condemn the use of ointments as filthy, barbarous, and apt, if rancid, to irritate the part. Like many other lofty views, this opinion could only be held by those who have tried the plan imperfectly, or not at all. There is no necessity for any filth, and no ointment should be used when rancid. Those who have used the benzoated zinc ointment freshly made will, I think, admit that it would be a pity were so useful a remedy abandoned in deference to any prejudice.

M. Rollet has lately tried to revive the use of the red-hot iron in certain cases, and speaks very highly of its powerful action in obstinate creeping sores. However well the plan might succeed in France, I doubt if any person could possibly introduce it here. I feel convinced that it is the best remedy ever yet discovered either for creeping or any other kind of sore. I tried it many years ago in some dozens of cases, all of which turned out well; but I should never dream of recommending it, because I don't believe one patient in ten would allow it to be used.

When the chancre is very painful, and the patient is prostrated and depressed in spirits, small doses of morphia may be given two or three times a day, along with pretty large doses of ammonia, in some bitter aromatic infusion, like cascarrilla or serpentaria. Purgatives, too, I think should always be given, particularly when the tongue is coated, to the extent of acting distinctly upon the liver and opening the bowels two or three times a day, and they may be repeated two or three times a week. Unless there is very decided induration it is rarely necessary to do much more than this. When, however, the chancre is very hard, iodide of potassium may be given in five-grain doses, at first twice, and afterwards three times a day; dilute nitric acid, in doses of at least fifteen or twenty minims three times daily in some little infusion, agrees extremely well with these cases. When an indurated sore is obstinate, tartar emetic given to the amount of half or three-quarters of a grain every two or three hours, will often make a speedy and most favourable change in it. The sore, too, may be touched in such cases with concentrated tincture of cantharides or Ballin's blistering fluid, the Spanish fly having apparently a great power of reducing granulation.

Induration of the site often remains long after the healing of hard chancre, and which is apt, after disappearing to a great extent, to return in a much more severe form than at first. Indeed, it sometimes attains an extraordinary size. I have seen it as large as a hazel-nut, and Mr. Holmes Coote mentions a case in which the swelling reached the bigness of half a walnut.* But even much less than this will cause the patient a great deal of annoyance, and therefore it is best to employ at once some local means. Almost any good vesicant will do, such as

very strong tincture of iodine, solution of cantharidin in glacial acetic acid, ointment of the red iodide of mercury, &c.; but perhaps the best of all is the acid nitrate of mercury, recommended by Mr. Gay. Ointment of the white precipitate of mercury is a gentle yet efficacious remedy; even this freely rubbed in will produce vesication, sometimes followed by suppuration, in the body of the hard mass which opens by a minute orifice. After this the part rapidly shrinks.

Very frequently after indurated and indeed other kinds of chancre, the patient is surprised at seeing an eruption of spots on the penis. Some of them appear in the form of bright red small papulæ; if within the prepuce, they yield a sero-purulent secretion. At other times small masses of tenacious yellow secretion form on the surface of the glans penis, apparently at the orifices of sebaceous ducts, adhering firmly, and when detached, which is done with difficulty, leaving small, clean, conical pittings. Though this kind of eruption is not very uncommon, yet I am not aware that I have seen it described in any work. It may be safely left to itself, or if treatment is considered necessary, a little simple wash or water-dressing may be employed, and a purgative may be given.* But, except that antacids seem to have some power over these eruptions, and that purgatives judiciously given are suitable to every stage of syphilis, there is not much to be done by treatment, and indeed they disappear almost as fast under the unassisted efforts of Nature as under any system of management.

The *suppurating* chancre cannot be healed too quickly. It has already reached the phase essential to its cure, that of secreting pus, and the process of graining up is all that requires attending to; but this should be expedited in every possible way, as its remaining open can do no good, and may possibly (for we possess no certain knowledge on the subject) promote the formation of bubo. Free irrigation, at least two or three times daily, with hot water, mild aperients, rest, and light diet, are all the remedies really called for, and a piece of lint, wetted with simple water and covered with oiled silk, may, with the aid of the solution of sulphate of copper just spoken of, be safely substituted for all the lotions ever invented. Indeed, the very variety of these lotions is calculated to raise one's scepticism as to any great power they can exert over the healing of chancre, for it is only reasonable to suppose that amidst so many hundreds of formulæ some few would, by right of superior virtue, have acquired and maintained an undoubted supremacy.

This is beyond doubt the form of chancre most frequently followed by suppurating bubo, a primary, not a secondary affection, as if inoculated, it reproduces the suppurating chancre directly. Seeing that the arrest or development of bubo has not the least influence over the course of the disease, it behoves the surgeon by every means in his power to check, and if he cannot do that, to limit the suppuration.

When I publicly stated some years ago† that arresting the suppuration has as little power in bringing on secondary syphilis as fostering the suppuration has in averting this dreaded result, it met with general opposition. I believe the statement will be received now, and certainly I see no reason to modify it. It is quite true that after a chancre has formed a bubo will arise and threaten to suppurate. The formation of pus is checked by the energetic use of proper means, and then, if secondary syphilis follow, it is always attributed by the patient, and sometimes by the surgeon also, to interference with the course of Nature, which would have discharged the virus by its only proper outlet. As if to corroborate this view, it is equally certain

* Such as, for instance, magnis sulph. ℥ss.; magnis calc. pond. ʒii.; potass. nitr. ʒiiss.; tinct. zingib. ʒii.; aq. menth. pip. ad ʒvi. Coch. anip. ii. omni mane. Pil. coloc. comp. ʒss.; pil. hydrarg. ʒss.; ext. hyoscyam. ʒi. M. et divide in pil. xii., i. vel j. omni nocte.

† In a paper read before the Western Medical Society, Nov 19, 1858.

* A Report of some of the more important Points connected with the Treatment of Syphilis, 1857, p. 89.

that suppurating bubo is very rarely followed by secondary syphilis.

But there are reasons for this enigma, which, I trust, will bear out the assertion just made. Suppurating chancre is followed by two kinds of bubo, the inoculable, or that which, at a *certain stage*, yields a pustule when its pus is properly inserted beneath the cuticle, and the non-inoculable, in which this result does not follow. Though frequently confounded, they are as distinct as any two results of syphilis. The bubo, which generally accompanies sores with very little thickening or hardening, almost always ends in suppuration. The only remedy I have ever seen exert an appreciable influence over this result is tartar emetic. Otherwise the invariable course of the inoculable bubo is, that it bursts when not opened and yields pus, which, however frequently tested, never fails to generate a pustule from which we can again inoculate. It is a singular fact, which I have often verified, that so long as we open this bubo, and, having got out the pus, close the opening so thoroughly as to prevent its edges from ulcerating, the pus does not produce a chancre, and this I have frequently done. But whether this bubo be allowed to ulcerate or not, secondary symptoms rarely follow, if ever, so that we have everything to gain and nothing to lose by arresting the abscess.

19, Devonshire-street, Portland-place.

HOSPITAL REPORTS.

(FROM OUR SPECIAL REPORTER.)

KING'S COLLEGE HOSPITAL.

PULSATING TUMOUR AT THE ROOT OF THE NECK.

(Under the care of Sir W. FERGUSSON.)

THE following case has created an unusual amount of interest in King's College Hospital:—

M. W., *æt.* 43, has been a sailor, principally in hot climates, since he was thirteen years old. On his last voyage, on October 1st, 1864, he fell, striking the bowsprit, and was lifted insensible from the water. On recovering consciousness he discovered that his right arm was powerless. There was no surgeon on board, so by the advice of the captain he had the arm, chest, and back, on the right side, covered with pitch plaster. Six weeks after this the surgeon at Aden found that the collar bone had been broken at the junction of its inner and middle thirds, and had not reunited. At this time a small pulsating tumour had made its appearance (he says) about two inches above the clavicle. Subsequently he spent seven weeks in the Bombay Hospital, when the tumour alluded to was considered an aneurism of the innominata; it steadily increased, and for the last six weeks of a tedious voyage home round the Cape, did so rapidly. On his admission under the care of Sir W. Fergusson, it had grown to a large size. The bones had disappeared, and a pulsating tumour with ill-defined margins extended from the third rib below to the parotid above, from the acromion of the right side to the sterno-clavicular articulation upon the left. On the right side the pulse seemed oppressed, the right arm slightly swollen; breathing was slightly impeded. There were no cerebral symptoms.

Chlorodyne, opium, &c., were given, but on November 7th, the aneurism was evidently spreading towards the left side; he suffered from cough and dyspnoea while recumbent.

Ten days after this the swelling increased towards the right axilla, and he vomited.

October 30th, the tumour was painted with gutta-percha dissolved in chloroform, but this covering cracked through the expansion of the tumour; the skin seemed inflamed; a superficial abscess formed, and close by the latter the aneurism seemed to "point."

December 17th, the skin began to ulcerate, and he com-

plained of pain in his shoulder and arm; great dyspnoea and dysphagia now occurred.

January 2nd: The tumour burst and a small quantity of blood was lost before the nurse arrested it by pressure and compresses, or Ferri Mur. could be applied. Veratrum viride, digitalis, &c., ordered.

5th: The cough was alleviated by *trœ opii*, ʒss., every four hours, but he complained of great pain in the arm. At ten p.m., blood again flowed and escaped by many points from beneath the compress. Under this pressure the aneurism subsided so suddenly and completely that the dressers who had been in constant attendance thought it had burst internally. He died in about twenty minutes.

Post-mortem examination.—Kidneys congested, right, six and a-half ounces, left, six ounces. Spleen healthy, nine ounces. Liver congested. Lungs healthy, small. Heart healthy.

The clavicle was found to be fractured, and the broken end could be felt through the opening in the skin. The whole bone as far as the acromion was stripped of periosteum. The manubrium had been removed by absorption. The aortic arch was found much dilated, and at the base of the innominata there was an oval opening which communicated with a sac extending from the trapezius and deltoid above to the lower rib; under these muscles were found many clots of blood. Sir W. Fergusson's first opinion was that this was a subclavian aneurism, but he soon became of a different opinion, and now it seems that the innominata had been injured by the sharp end of the clavicle, a false aneurism formed, which had burst, and a secondary sac formed by the blood forcing its way through the cellular tissue and intermuscular spaces.

This case is a striking illustration of the difficulty which every surgeon finds in determining the starting points of all tumours at the root of the neck. The complication of a dilated arch of the aorta, with fracture of the inner third of the clavicle, is also very important, and the position where a small pulsating tumour was first noticed. The greatest credit is due to Mr. Howells, the house-surgeon, Mr. Blythman, and relays of dressers who sat up night after night with this poor man, and prolonged his life for several days.

Case 2.—There is another anomalous case of pulsating tumour, but not aneurismal, at the root of the neck, on the left side, with a distinct bruit; the patient, a widow, has been the subject of rheumatism. The principal symptoms are puffiness in the left posterior triangle, and enlargement of the superficial veins of that neighbourhood. Sir W. Fergusson proposes to treat the following case by flexion of the leg.

POPLITEAL ANEURISM.

Case 3.—A man, *æt.* 31, fruiterer, of robust build, but addicted to spirit drinking, and of a rheumatic tendency. He has a pulsating tumour in the right popliteal space. He first felt a pain, supposed to be rheumatic, about four months before his admission upon January 12th, and gradually the present swelling made its appearance. Aortic and mitral disease render operating proceedings unadvisable before trying other measures. The patient is evidently an unfavourable subject for any kind of treatment. In addition to the history of rheumatic disease, he bears the marks of a recent syphilitic eruption, and his left hip-joint is ankylosed.

TUMOUR IN THE HYPOGASTRIUM.—UNDESCENDED TESTICLES.

The following case has been under the care of Sir W. Fergusson for several weeks.

Case 4.—B. D., *æt.* 34, married, childless, testicles undescended, but no further peculiarities in his pudic or inguinal regions. Ten years ago, about which time he received a severe blow on the lumbar region, a small swelling appeared in the left groin. This was movable, and could be pushed backwards and upwards into the belly; it was mistaken for a rupture returned half a dozen times by different surgeons, and he was desired to wear a truss,

which he did until eighteen months ago. The supposed rupture had extended upwards and downwards, and was then as large as an ostrich's egg. At St. Bartholomew's Hospital it was tapped, and ℥xxiij. of straw-coloured fluid was drawn off. Eight or nine months afterwards he returned, and ℥xvi. of dark-coloured fluid was withdrawn, and on a second occasion ℥xxxij. of porter-coloured liquid were taken away. After these tapplings the tumour never wholly disappeared, and he now began to feel numbness and cold in the left thigh. On admission, November 24th, 1865, his scrotum was small and empty, it was pyriform at the base, about the size of a fœtal head; upwards it occupied the hypogastric and iliac regions, without any definite boundaries; below, Poupart's ligament could be distinctly felt. The mass is divided into two unequal portions, the upper, the smaller. The tumour is opaque, elastic, tremulous on percussion, and has a distinct impulse on coughing. Cannot lie on his back or right side.

December 5th: Oij. ℥v. were drawn off by tapping; as it flowed the liquid gradually assumed the colour of port wine, was opaque, and deposited a copious red sediment. This reduced the tumour about one-third, and allowed a movable body to be felt.

6th: The swelling was rather larger than before tapping. The seat of puncture was swollen and tender.

16th: A longitudinal incision was made over the centre of the tumour for about three inches, which gave exit to a quantity of dark blood mixed with clots and grey fibrinous masses; about Oiiijss. were removed. After this a more limpid fluid was seen to issue from the outer side of the incision, from a smooth sac lying between the abdominal muscles and the skin. These proceedings reduced the tumour to about one-fourth.

January 1st: Discharge from the wound purulent. Pulse soft, full, 108; belly tympanitic; purging and vomiting.

8th: Some slight improvement which did not last, and he has gradually sunk until to-day (15th), when he is moribund.

Proceedings of Societies.

SURGICAL SOCIETY OF IRELAND.

Dr. WILMOT, President of the College, in the Chair.

A MEETING of this Society was held on the evening of Friday, 5th January, at the College of Surgeons.

CASE OF CIRRHOSIS OF THE LIVER WITH ASCITES, SUCCESSFULLY TREATED BY IODIDE OF POTASSIUM: RETURN OF THE ASCITES: DEATH.

By Dr. MAPOTHER.

The patient, John Ryan, a railway porter, was first admitted under my care into St. Vincent's Hospital in Nov. 1860. He was then aged 40. The abdomen was very full of fluid, and that this condition depended on contraction of the hepatic tissue appeared from the absence of other dropsy; large veins on the surface of the parietes, a slightly jaundiced hue, and the man's intemperate habits. He had been already twice tapped in a county infirmary, although his dropsy had been but of four months' duration. As he was otherwise pretty healthy, it was thought that a trial should be given to medical treatment, and as the effused lymph was apparently so recent, iodide of potassium was judged to be the agent most likely to promote absorption. Five-grain doses, gradually increased to ten, were given thrice daily, and the ointment of that salt was applied to the abdomen over a surface one foot square, the cuticle having been previously removed by blistere. The fluid gradually disappeared from the peritoneum, and at the end of three weeks was all gone. I saw him frequently afterwards, as I was passing his station, in excellent health. But his dropsy at last returned, and he was again admitted into

hospital in August, 1865. The same treatment as before, as well as purgatives and diuretics, including the application of infusion of broom to the abdominal surface, was tried, but without relief, and we were forced to tap the cavity on October 1st. Thirty-five pints of serum flowed away. About fifty hours after the operation complete coma supervened and continued for thirty hours, when it very suddenly disappeared. During this period his full pulse and warm extremities indicated that it was not the insensibility which mere weakness of circulation would produce, nor was it ureal poisoning, for I drew away, by three introductions of the catheter, forty ounces of very normal urine. Complete cessation of the excretion of bile seemed the most probable explanation. On the fifth day after the operation the puncture reopened, and discharged, occasionally with force, many pints of serum. He became very gradually weaker, and died four weeks after the removal of the fluid. As the specimen exhibits, the liver was contracted, hard, and nodulated, the spleen vicariously enlarged, and the right lung, so long compressed, had assumed, throughout almost the entire lower lobe, that condition known as atelectasis. Every other organ in his body was healthy. The points on which I invite an expression of opinion are, the treatment of cirrhosis by iodide of potassium and the cause of the coma which supervened after tapping.

Dr. BENSON believed that cirrhosis of the liver was generally attributed to the irritation produced by ardent spirits, and no doubt often proceeded from that cause; but he recollected one case in which a child eight years old was affected by that disease, and there was no reason to suppose the child had used any of the ordinary stimulants. It was so unusual that he would not say he diagnosed it during life, but the post-mortem examination revealed it, and it was a well-developed case of the disease. The liver had that remarkably nodulated appearance characteristic of cirrhosis, and when cut into had that appearance of tubercular structure so common in that disease.

Dr. MACSWINEY said that Dr. Todd denied altogether the theory that cirrhosis of the liver was caused by the use of ardent spirits, and he mentioned several cases of children affected by the disease who had come under his observation. Many authorities, however, mentioned that it was the use of whisky—that is, of spirits rather than wine—ale, or diluted spirit which gave rise to cirrhosis. The explanation was, that the spirit was absorbed by the veins, and that in a comparatively undiluted condition it made its way to the liver and exercised a stimulating effect there. The fact of the man being operated on was interesting in the view of its being a practical procedure, because he had known objections raised against taking away the fluid in cases of ascites. He had himself resorted to operation twice with beneficial effects, but the man died on the second occasion from acute peritoneal inflammation, set up by the operation of paracentesis. He thought it would be hardly possible to diagnose cirrhosis of the liver from negative symptoms merely, and he considered the symptoms mentioned by Dr. Mapother—viz., the jaundiced appearance, large veins on the abdomen, and intemperate habits of the man, were scarcely sufficient to enable the physician to pronounce positively as to the nature of the disease.

Mr. B. W. RICHARDSON observed that one of the most interesting points of Dr. Mapother's case was the coma under which the patient for some hours laboured. Many years ago Dr. Griffin recorded in the *Dublin Medical Journal* some cases of jaundice in which coma was a prominent symptom, and the late Dr. Graves likewise published similar cases, the particulars of which were sent to him by Dr. Hanlon of Portarlington. Dr. Budd also, not only alludes to those cases but gives others of a like nature in his valuable work on diseases of the liver. Although in the cases mentioned by these gentlemen the patients were deeply jaundiced, the symptoms cannot be explained by the presence of the bile which circulated in their blood, for people may be

jaundiced for months without heal symptoms supervening. It has been imagined that a poison is present in the system when coma and convulsions occur in jaundice, and notwithstanding that Dr. Mapother's patient was only slightly jaundiced, if the poison theory is the correct one, it is possible some toxic agent was in operation in the case. He begged to ask Dr. Mapother if he examined microscopically the secreting structures of the liver before us, and what was the condition of the hepatic cells?

Dr. HAMILTON asked if there was any hæmatemesis during the case?

Dr. MAPOTHER said there was none.

Dr. BENSON observed that when the liver secreted bile, which was absorbed into the system, jaundice was produced; but this did not affect the system so much as where there was inaction of the liver, so that bile was not secreted at all and the material of it remained in the blood. It was a semi-jaundiced appearance that the patient got in cirrhosis, sometimes a blueness or lividity of hue, not the golden colour which was characteristic of regular jaundice. If that would account for the coma it would not account for the disappearance of the coma afterwards, which was what appeared so strange.

Dr. FOOT observed that Dr. Stokes referred to the existence of moderate jaundice in cases of cirrhosis of the liver, and laid down a formula for diagnosing this disease—viz., moderate jaundice, ascites, varicose veins over the surface of the abdomen, and diminution of the hepatic tumour. In many cases the diminution of the hepatic tumour could only be made out after tapping, which he recommended.

Dr. FLEMING asked whether the coma increased during the administration of the large quantities of iodide of potassium, and whether Dr. Mapother stated the application of it was applied to a surface which had been blistered, and what was the effect of such application? He recollected having on many occasions thrown into the rectum, with a view to relieve the enlargement of the prostate gland, injections of iodide of potassium, and it produced agonizing pain, even where the mucous membrane was healthy.

Dr. MAPOTHER, in reply, said he thought the diagnosis of cirrhosis of the liver was established by the man having a slightly jaundiced hue, by his intemperate habits, and by his having ascites only, being without any disease of the heart or kidneys, and also by the large veins on the surface of the abdomen. There was no dropsy of the extremities, but ascites only—a form of dropsy so usual in cirrhosis of the liver. He referred to THE MEDICAL PRESS, in which the case would be found described as cirrhosis of the liver five or six years ago, and the post-mortem examination verified the statement which he made at the time. In answer to Dr. Fleming, he had to state that they gave the patient large doses of iodide of potassium internally, and then applied blisters to the extent of one foot square, which they dressed with iodide of potassium ointment. He experienced a little pain at first, and there was a semi-purulent discharge, but it was not complained of by the man, who was a very patient person. The coma, apparently, had nothing to do with the administration. The coma, which was the most remarkable thing about the case, he could not explain. It continued thirty hours, and suddenly disappeared in the middle of the night. During those thirty hours he relieved the bladder on four occasions, and without any relief to the comatose condition. The coma set in fifty hours after tapping, and he recovered completely, lived some weeks afterwards, and sank from simple debility.

Mr. CROLY asked if the brain was examined in this case, and whether the exhaustion of the system and an anomalous condition of the brain might not have given rise to symptoms which were relieved by stimulants?

Dr. MAPOTHER—The brain was examined and no pathological appearances whatever were presented. No doubt loss of blood would produce coma, but that could not have

been the case in the present instance, as there was none, and the brain was perfectly normal.

DISEASE OF THE KNEE-JOINT.

Mr. CROLY exhibited a Knee-Joint which he had removed after death from a patient in the City of Dublin Hospital. The man, who was 45 years of age, was admitted on the 17th of October into the hospital, suffering from all the ordinary symptoms of chronic synovitis. He had a pale anæmic look when admitted; the right knee-joint was swollen; the swelling was more marked on the inside; there was a good deal of fluid in the joint; the tibia was displaced backward with the fibula. He placed the patient in a well-padded McIntyre splint, and gave him a liberal diet with wine and quinine. The man recovered his strength and got fat in the hospital. The joint he treated with blisters, extending them to heal, and strapping it all with the ordinary Scots bandage. The swelling went down, and the man complained of pain over the internal condyle and over the anterior part of the tibia. His condition improved, and he (Mr. Croly) looked forward to the joint becoming ankylosed, but a month ago the pain increased in the joint, and he fired the joint, by which operation the man expressed himself much relieved and called for it again, and this had occurred several times in the hospital, when the cautery was repeated. In showing this case to the class he mentioned the leading features of it, and on many occasions they pressed his heel to see if he would complain of pain, but he never complained of pain on percussing the heel, and there was no lateral movement of the joint. He therefore looked on the case as one of chronic inflammation of the joint, with effusion, and he confessed he did not look on it as one of ulceration of the cartilages. On the 25th of December he was greatly struck by the alteration in the man's appearance, although when going round on the morning before he saw the man looking as well as usual. About a week before that, an abscess formed near the head of the fibula and burst, and emptied itself, giving him some relief. On the 25th he observed a sudden change in the man's appearance. His countenance was extremely pallid. He asked him what happened, and he replied that he had a severe shivering fit on the night before. There were a great many cases of erysipelas in the hospital, and he was afraid the man was about to be attacked by it. There was, however, no redness of the skin. He examined the man carefully and there was no heart or kidney disease to account for such a sudden change in his appearance. His pulse became feeble, and he feared he was about to be attacked by pyæmia. He ordered him a stimulating mixture, punch and ammonia, and warm applications to his feet. His intellect was clear, but he gradually sank and died. He had no further rigors, but he gradually died from exhaustion. He opened the knee-joint, as if excising it, and he found a large abscess in the region occupied by the subcrural bursa. The anterior crucial ligaments were sound, but on raising up the patella he was surprised to find not a bit of the cartilage left. The semilunar cartilages were destroyed. The end of the femur was soft and diseased. The tibia was found to be soft; the cartilages were partially removed from the upper surface of the tibia. He then opened the cavity of the chest, and made a careful examination of the lungs, but found no disease. He examined the heart and it was healthy, and the kidneys and liver were also perfectly sound. In short, he failed to find any cause for death, which must, therefore, have resulted from poisoning of the blood from the veins of the joint which had become inflamed. He was struck with the appearance of the spleen. There was a curious cartilaginous growth on the surface, but no purulent deposit in the body of the spleen. If he had anticipated the state of the man's joint he would have recommended amputation.

The PRESIDENT asked whether Mr. Croly thought the disease originated in the synovial membrane?

Mr. CROLY—The absence of grating, &c., made him

think that this was a disease of the synovial membrane only and not of the cartilages.

Mr. B. W. RICHARDSON said that at one time it was considered that if pressing diseased articular cartilages together caused pain, it should be attributed to ulceration or disintegration of cartilage. There can be no doubt, however, that cartilage may be destroyed without the individual being aware that anything was wrong with the joint. As practical surgeons are, notwithstanding, aware that pressing together the articular surfaces forming a diseased joint frequently causes great torture; as such pain may be caused by pressing the bones together, and from which the cartilage has disappeared, some surgeons refer the pain rather to the osseous disease than to the ulceration of the cartilage. Indeed many excellent observers, Mr. Redfern and M. Richet among the number, think, that the violent spasms and pains so frequently experienced by persons labouring under certain joint affections, instead of being attributed to, and being pathognomonic of, ulceration of cartilage, should rather be referred to stripping of the diseased joint bones, the consequence of the destruction of the incrusting cartilage.

Dr. GRIMSHAW asked if the surface of the spleen had been examined under the microscope, and, if so, what was the character of it?

Mr. FLEMING said this case was one of great practical moment, and impressed on the mind the importance of accuracy of diagnosis and prognosis. Diseases often advanced to a very considerable extent without the slightest manifestation of symptoms during life. Disease of the kidneys was often very extensive, and yet during life there was not one symptom of the disease. In the present case there were some manifestations of disease apart from pain, and that from the enlarged condition of the bursa of the extensor tendon. He did not attach much importance to the appearance of the spleen. That morbid condition might have existed for some time, and was probably identified with the capsule of the spleen itself.

Mr. CROLY, in reply, observed that he thought the cartilaginous growth on the surface of the spleen could be seen as well with the naked eye as with the microscope. It was attached to the capsule of the spleen, and he removed the spleen merely because he had never seen that condition of the organ before. He thought the sudden death of the man was the important point to put on record. When a man had ordinary disease of the knee-joint if he got worse it was generally by diarrhoea and sweating, but here was a case where the man was going on well when he was suddenly attacked and died. Death had evidently been caused by blood-poisoning. It was preceded by a rigor four days before.

ILL EFFECTS FROM SWALLOWING GLYCERINE.

Mr. B. W. RICHARDSON mentioned that he was sent for a short time ago to see a child who had taken a large quantity of glycerine. The mother of the child had been using Price's glycerine, and the child got at the bottle and drank nearly half a pint. The child lay as if dead, and he was sent for, but it revived before he arrived, about half an hour from the time of swallowing the fluid. It was interesting to consider what caused the insensibility. Was it owing to the weight of the glycerine and its intense sweetness acting upon the stomach? There was deadly sickness, and the child revived after vomiting.

Dr. MACSWINEY thought if the child took half a pint of thick syrup it would have the same effect. Price's glycerine was usually very pure.

CROUP.

Mr. CROLY exhibited a morbid specimen which he had removed from the body of a child in the City of Dublin Hospital. The case had been sent to him by Dr. Hewitt, who met with it when doing duty in one of the city dispensaries. The child, which was about two and a-half years old, was

attacked with all the ordinary symptoms of acute croup, and he might mention that he had met a great number of such cases lately in connexion with the South City Dispensary. The child had stridulous breathing, a very rapid pulse, its head inclined to be thrown backwards, congestion of the veins of the neck, and urgent dyspnoea. The pulse was so feeble that he looked on the case as one certain to be fatal, and one that would not bear depletion or any lowering treatment. He prescribed ipecacubana with wine, and squills and hot sponges to the throat. The child refused to swallow, and the resident pupil injected wine with ether into the rectum. The symptoms increased, and the child died. In examining the parts below the bifurcation of the trachea he found no false membrane. There was much vascularity about the rima glottidis, as if there was more mischief at the beginning of the windpipe than in the trachea itself.

The question that he would wish to have discussed would be, whether, in this case, if he had opened the trachea, the life of the child might have been saved by the operation. The late Mr. Porter strongly condemned the operation of tracheotomy in cases of croup. Trousseau was not only an advocate for it, but he recommended it in very early stages of the disease. He would not, however, get many Surgeons in Dublin who would follow his advice. Statistics proved that it was a most fatal operation. Had he known that there was an absence of false membrane he would have attempted the operation of tracheotomy.

The PRESIDENT observed that the fact that one could not prejudice the case was a strong argument in favour of operation.

Dr. FLEMING asked what was the condition of the lungs?

Mr. CROLY said they were slightly congested. He might mention that the thymus gland was very large, and still did not interfere with the region in which tracheotomy would be performed. There was an inch of space for the operation.

Dr. McCLINTOCK asked if there was any croupy breathing?

Mr. CROLY—Yes; it was as well marked a case of croup as I ever saw.

Dr. McCLINTOCK said he had seen several cases of croup in which there was a marked absence of croupy inspiration. There was loss of voice and embarrassment in breathing, but there was an absence of the croup. The children he saw with one exception recovered. The child who died was brought to his study in a very exhausted state, and it died that night.

Dr. HEWITT said that he saw the case now under consideration in an early stage, and several cases came under his notice lately, some of which were fatal. The moment he went into the room he was struck with the brazen sound of the breathing. Last year there was published a number of cases in a Norwegian journal, and out of twenty-three cases in which tracheotomy was resorted to there were eighteen recoveries.

Dr. CROLY had seen cases in which the disease spread by contagion or infection to others of the family, but the type of disease was not the same as in past years. It was of a much milder character and more amenable to treatment. He had not heard of any cases proving fatal.

Dr. McCLINTOCK said the most important point connected with this case was that in reference to the propriety of operation; and although the weight of opinion in Dublin was against operation in such cases, yet the subject might be deserving of reconsideration. Dr. Whittle of Liverpool, who had studied in Dublin, published a paper some time ago in the *Dublin Quarterly Journal*, in which he strongly advocated tracheotomy in a particular class of cases of croup. He described one class of cases in which, although there were the usual symptoms of croup, there was little or no false membrane formed, and it was in that class of cases he would resort to operation which would generally, he said, prove successful.

Dr. HAMILTON said it had often struck him, in reference

to these statistics from the Continent, that many of the cases operated on would have recovered without any operation, or they should be considered as a different disease from what we had in this country. He did not think the same amount of success would follow in operations for croup here. The objection to operative interference was, that one could not be certain that a false membrane did not exist below the point where the opening into the trachea must be made.

Dr. MACSWINEY thought the reopening by that Society of the question of operation in cases of croup was calculated to do much good.

Dr. BEATTY said it must always be recollected that, in dealing with an advanced case of croup, the surgeon was not merely to confine his ideas to the false membrane in the trachea, but should remember that in a large percentage of cases it extended down into the minutest ramifications of the bronchial tubes, and therefore, although air might be let into the trachea, it did not follow that the child would be enabled to breathe. As to the operation in an early stage of the disease, if they could only diagnose the cases where there was no false membrane, no one would hesitate a moment in resorting to an operation, if it were a safe one, under the circumstances. But even if the child were healthy they were not certain that the opening into the trachea would not kill it. In Dublin the operation of tracheotomy had been the subject of mature consideration by very wise men, and non-interference came to be the practice.

Mr. CROLY observed that he had seen many cases, and put them on record, in which croup had been cured by medical treatment without resorting to operation. His own child had acute croup, and by proper treatment the child's life was saved, whereas tracheotomy would have killed it.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JAN. 9, 1866.

Dr. ALDERSON, F.R.S., President.

ON CERTAIN PRACTICAL POINTS IN THE PATHOLOGY AND TREATMENT OF LATERAL CURVATURE OF THE SPINE.

By RICHARD BARWELL, F.R.C.S.,

ASSISTANT-SURGEON TO CHARGING-CROSS HOSPITAL.

CERTAIN cases under the care of, certain investigations undertaken by, the author, led him to perceive that the lateral flexibility and rotatory power of the spine during movement of the limbs had not received sufficient attention either in a physiological or curative point of view. The results of his experiments may be thus briefly stated. The act of walking produces serpentine undulations of the spine. When the weight is on the left leg, and the right behind about to be lifted from the ground, the lumbar spine curves to the right, and the dorsal to the left. In bringing the right leg forward, the column straightens; and, when that foot is put down, the curve reverses, again becomes straight as the left foot is brought forward, and so on. Some peculiarities of these inflexions induced the author to extend the number of his observations on living persons. The lateral movements of the spine, as above described, were found constant in character, various in amount, and with each lateral bend a commensurate amount of rotation takes place. The spinous processes always incline towards the front of the vertebræ from the cord of curvature. In fact, Mr. Barwell declares the spine incapable of assuming a lateral bend without at the same time undergoing rotation, which although, perhaps, in part due to the reason given by Shaw, the sideways distribution of the weight, is also caused by the lateral and posterior position of the forces which bend the spine, and more especially by the action of the semispinalis dorsi and

rotatores spinæ muscles. To ascertain the amount of rotation of which the spine is normally capable, the average of ten experiments was taken. The normal rotation-average was $43^{\circ} 17'$; the largest amount just over 49° . Movement and weight-bearing with the arms also produce a certain amount of lateral flexion, whose object is twofold—fixation of the spine as a sure basis of action for the shoulder, also balance and economy of power. This flexion is not produced by direct action of the muscles passing between spine and scapula, but by the spinal muscles proper on the opposite side. Thus the column is constantly bending laterally and rotating. These positions are, therefore, not in themselves abnormal, but may become morbid either by fixity or amount. A posture much beyond what the spine can normally assume may, nevertheless, be simply due to muscular action on the one side, inaction on the other; but such cases will (unless treated) overstep the limits of any posture muscular force can produce, and are then due also to some external agency—weight, relaxation of ligament, alteration of bone surface, &c. But these organic changes are always secondary. Want of balance between muscular forces, either by redundancy or deficiency, is the primary and efficient cause of lateral curvature; and our treatment must be directed to restoration of that balance. The mere transference of a weight always carried on one arm to the other side, will not merely be inefficient, but often injurious; so also are many of the exercises prescribed for the left arm. The author, taking advantage of the necessity of balance, and the consequent normal tendency to form double curves, throws the spinal column out of its abnormal balance and rest on the ligaments by causing the pelvis to slope downwards from left to right, thereby necessitating a lumbar curve to the right, a position which, if carefully watched, cannot be long maintained, without producing a contrary curve in the dorsal region. Thus in both parts of the spine a posture the reverse of the abnormal is enforced, not by machinery, but by muscular action. Several exercises are used by the author. A few are described as most potent:—1st. The sloping seat, with a fall commencing at an inch and a-half in the foot, used for a quarter of an hour thrice a day. 2nd. Lateral gyration of the body, in strict measure, with the back against the wall, the pelvis sloped by a block under the left foot. 3rd. The patient, standing with the feet together, knees straight, a block under the left foot, lifts the left hand over the head, and in it is placed a spring attached above and to the right side. This is extremely potent, and requires careful watching. Certain other contrivances—viz., a thicker sole to the left boot, weighting the right leg and left arm, are used only late in treatment. Against rotation, the following exercise is given: The patient, standing with the right shoulder about three inches from the wall, lifts the left hand over the head, and leans over till it comes against the wall, and supports some of the weight. She then, with the feet together, passes the head and right shoulder under the left forearm, and tries to see as much as possible behind the left shoulder. All these exercises must be used with caution and generally in the order above given, though variations may occur for particular cases. After each, horizontal repose is to be enforced. In all but very slight cases, these exercises will not suffice without some form of support. The machine commonly called a spinal support is false in principle, aiming at superseding muscular action, thereby weakening the muscles; moreover, it is clumsy, heavy, and barbarous. If it fulfilled its office of keeping pelvis, spine, and shoulder stiff and immovable, it would be unbearable; not fulfilling its office, it is merely irksome and inefficient. A patient with moderate curvature can be straightened by placing one hand on the point of greatest dorsal excurvation, the other in the opposite axilla, and pressing in contrary directions. The bandage invented by Mr. Barwell is so contrived as to prolong this action in the same directions. It consists of webbing straps secured to the pelvis, to the right side below the

point of greatest curve, and to the left shoulder. In certain parts of the webbing, strong india-rubber springs are placed in such wise that the forces act from the pelvis exactly in the directions of greatest mechanical advantage, such as in practice are found most efficacious in straightening crooked spines. By placing the pad at the right side, a little posteriorly, much power may be exercised on the rotation. The construction of the bandage is such that there is no tendency to flatten the ribs against the spine. The whole apparatus weighs but a few ounces, is worn with ease and relief, and is very efficacious. By means of the exercises above described and the bandage, the action of them being rigidly under surveillance, the author has been very successful in the treatment of even advanced curvatures, as is shown by the appended cases.

The PRESIDENT said that many present would be able to give opinions as to the author's able and interesting paper. He remarked that if such papers were not well received by medical societies, they would be read at societies for general sciences. For his part, he had an aversion to mechanical restraints. If girls were brought up as boys are, there would be fewer curved spines. The President then spoke on the bearing of mathematics on the subject, and said it was one dangerous to touch without a knowledge of the higher branches of mathematics. He spoke also of the risk of damaging the pelvis in trying to remove the curvature of the spine.

Mr. WM. ADAMS was glad that the subject of lateral curvature of the spine had been brought before this Society, as there were so many members present who could contribute to its elucidation. He had listened with attention to the paper in the expectation of hearing some new pathological facts, or some new theory of the production of lateral curvature, or some new system of treatment; but in all these respects he had been disappointed. Mr. Barwell had relied upon physiological experiments and observations upon the production of curvature in certain attitudes; but all that he had said upon these subjects had been long since brought before the profession in the very excellent treatise by Mr. Bishop, who had thoroughly investigated the subject from a mechanical and physiological point of view. Mr. Adams was glad to hear Mr. Barwell assert that the spine is incapable of undergoing any amount of lateral curvature without rotation of the bodies of the vertebræ, as this led him to the point (Mr. Adams) had long endeavoured to insist upon—viz., that rotation of the bodies of the vertebræ always accompanies, and, he believes, precedes lateral deviation of the spine. For the diagnosis of this condition, Mr. Adams relied upon the posterior projection of the angles of the ribs in the dorsal region, and the posterior projection of the transverse processes in the lumbar region, rather than upon any lateral deviation of the spinous processes. Mr. Adams believed that no lateral curvature, as judged of by these conditions, however slight, could exist without structural changes affecting the intervertebral cartilages and the oblique articular processes—in fact, that these conditions formed the diagnosis between functional and structural deviations, and practically constituted the broad line, on either side of which our treatment would differ. Previous to these structural changes, we might rely upon gymnastics and partial recumbency; and after these changes in the transverse relations of the angles of the ribs in the dorsal region, or the transverse processes in the lumbar region, we must rely upon firm mechanical support with partial recumbency. The result of Mr. Adams' experience had been to convince him that where lateral curvature of the spine existed in any marked degree, and before it amounted to an external deformity, it was essentially an incurable affection by any and every method of treatment. Mr. Adams did not believe that the structural changes which existed in the confirmed lateral curvature admitted of removal, or repair, so as to allow of the affection being cured, unless the case were treated in the earliest stage, and with youth and growth in

its favour. It was only in the slightest cases that we could hope to produce a cure. In severe cases of spinal deformity all the profession were agreed in recommending mechanical support as the only system affording relief and comfort to the patient. Sir Astley Cooper and Sir Benjamin Brodie always sent such cases to the instrument makers; but in the treatment of the slighter forms of curvature the greatest difference of opinion had always and still existed. Mr. Adams thought that attention to the diagnostic indications between structural and functional affections upon which he had insisted would lead to the treatment being determined either in favour of gymnastics or mechanical support; but the curability of any particular case must rest upon the evidence of the existence of structural changes. Mr. Adams believed that further experience would convince Mr. Barwell that the employment of elastic force, such as he now recommended, by means of straps, would be quite useless where actual curvature existed; and that either to arrest the increase of curvature or to produce such improvements as the cases admitted of, it was indispensably necessary to use firm mechanical supports.

Mr. BRODHRST remarked that Mr. Barwell had given no idea of the amount of curvature in the cases he had treated. He wished to ask Mr. Barwell if the curvature was slight or severe, commencing or confirmed. He had himself made many experiments, and had found that when rotation had taken place appliances were useless. He was surprised, too, that Mr. Barwell should have obtained such results from such a bandage. It had been given up in France. He (Mr. Brodhrst) had brought it over from that country in 1851, and had found it fail wherever there was anything like a fixed curve. Mr. Barwell had not told the Society of the nature of his cases, either by description or by photographs; and as he appeared to have made his experiments on healthy and vigorous persons, he might have arrived at the results he had announced. If he were to try his plan on severe cases of curvature, the trials would not justify his conclusions. Sir Benjamin Brodie had tried a similar method in early life, but had given it up, and had acknowledged that recourse must be had to mechanism when rotation had been established.

Mr. NAYLER stated that he should wish to ask Mr. Barwell how he proposed treating certain forms of lateral curvature, whether by the method just described or not; for example, the lateral curvature which is sometimes seen in young children, in whom it has existed from birth. Again, in older patients the septum of two curves is occasionally so abrupt as to constitute an angle rather than a curve, or there may be three curves, and the superior one situated in the neck; and lastly, he wished to ask how he would treat lateral combined with posterior curvature. There is this objection to the employment of muscular exercises as set forth by Mr. Barwell, that we cannot so accurately or nicely regulate them as to prevent their action on the convex as well as the concave part of the curve; and when this takes place the only possible consequence is an increase of the deformity. One essential condition in the treatment of lateral curvature had been completely overlooked by Mr. Barwell—viz., the removal of the superincumbent weight of the head and shoulders by means of the pelvic instrument, provided with a double crutch. Another point is, to have the pressure properly applied to, and constant in its action on, the weaker part of the curve. Mr. Nayler was greatly surprised to hear Mr. Adams say that lateral curvatures are, as a class, incurable. It was only when attended by certain complications, as when the ribs projected posteriorly, that our means were limited to prevent the deformity from becoming more aggravated. In other instances, and especially in early life, a favourable opinion as to recovery might be given.

Mr. BARWELL thanked the President for his kind remarks. It appeared to him strange that Mr. Adams should be disappointed with the amount of novelty in

this paper, for the experiments concerning lateral and rotatory movement of the spine during walking, those fixing the amount of normal rotation permitted by the column, the whole plan of treatment by throwing the spine out of its morbid balance on the ligaments, and other points, were new. He was sorry to hear from Mr. Adams that his experience caused him to look upon lateral curvature as utterly incurable; yet the enunciation of that opinion only confirmed Mr. Barwell in his conviction that the mode of treatment at present in vogue was quite inefficient—a conviction which had led him to make the above experiments and to devise a better method. The results did not lead him to the same sad conclusion as that to which Mr. Adams had come. The author was surprised to hear from Mr. Brodhurst that a belt similar to his own had been made in Paris, because no mention of such could be found in any one of the many French, German, or Italian writers on spinal curvature, and its construction was the result of entirely independent thought; but Mr. Barwell could well believe it must be ineffective if tried alone, for it is not intended to be so used. The oblique bandage is an adjuvant—a very valuable, indeed a necessary, adjuvant to his method of exercising the spinal muscles when thrown by the position he enforces out of their abnormal posture of repose. Finally, Mr. Barwell showed some photographs from severe cases of curvature, dorsal and lumbar, some of which were cured, others in the course of improvement.

Reviews.

AUSTRALIA FOR THE CONSUMPTIVE INVALID; the Voyage, Climates, and Prospects for Residence. By ISAAC BAKER BROWN, jun., late Surgeon-Superintendent H.M. Emigration Service; Assistant Surgeon to the London Surgical Home. Hardwicke, Piccadilly, p. 138, 8vo.

In the present day there is no lack of books and pamphlets advising those who suffer, directly or indirectly, from our variable climate, to seek health away from home. It is hardly too much to say that at the present rate, there will soon be no sea-girt island or sea-exposed town or village between the latitudes 50 deg. and 60 deg. that will not have its own special medical champion. The more renowned sanatoria in France, Italy, Egypt, and the Island of Madeira, may be all very well for those who, having plenty of money, care not where they live so long as they live in health, but the very large majority of the places whose climate is recommended, offer no inducement to the man of limited means, nor have they any resources which are available as a help towards a living when the invalid is restored to health.

Mr. Brown, who in his capacity of Surgeon-Superintendent in the Emigration Service, has more than once visited Australia, and brings before the notice of the profession and public generally the eminent suitability of what he graphically calls England's "golden child," as a residence where a man can, if he have money, put it out to good interest; and having found health, will be able to find scope for his restored energies in any trade or profession to which he may have been educated. Mr. Brown says (page 73):—"Australia is a glorious, healthy, fertile, rich, prosperous, and money-making country; so large, that if all Great Britain went there, there would still be room for the greater part of Europe; so rich in its mining, agricultural, and pastoral resources, that the only cause of drawback is want of sufficient capital for investment; and when it is stated that the banks will give seven and eight per cent. for money deposited; that there are many good and safe investments realizing ten to twelve per cent., not to mention gold mines, a speculation of more fluctuating character, or sheep runs when capital is speedily doubled, more is hardly necessary

to prove that Australia is a prosperous and money-making country."

Mr. Brown goes at some length into the various resources of this vast territory, and combats very successfully, we think, the false notion that many English people have of the state of society and civilization generally at the Antipodes. He also gives interesting information with reference to the various amusements and pursuits of the country.

To come to the more *immediately* medical portion of the book, we find Mr. Brown well able to speak from personal experience of the various Australian climates. Believing that a climate which has at the coldest season a temperature far exceeding that to which one has been formerly accustomed in the height of summer, cannot be beneficial, Mr. Brown prefers Tasmania, the north of New Zealand, South Australia and Victoria, to New South Wales, or the still hotter colony of Queensland. Tasmania is preferred as being much freer than the main land from the scourge of the colonies—the hot north and north west winds. "The temperature of Tasmania is similar to that of the south and south-western parts of England. The mean annual heat of Hobart Town is 52 deg., the mean of summer 63 deg., and of winter 44 deg. At Launceston it is warmer, the climate resembling that of Lisbon in winter, while in summer it is no warmer than Cheltenham." We find in Tasmania many products of vegetation to which we are accustomed in England. Such plants will not bear the hotter climates of the more northern colonies, but grow with great abundance in Tasmania. To come to statistics, Tasmania shows less than eight per cent. of deaths from consumption, as compared with nearly eleven per cent. in Victoria.

The chapter, however, which we imagine will be found most useful, not only to invalids, but to all intending voyagers, is No. XI. Here every information as to choosing a ship and cabin are given. The fact that on the port side of the ship a passenger is more likely to get fresh air than on the starboard, is here quoted as an evidence of the practical value of experience. The caution as to the discomforts likely to be experienced by trusting too confidently to one's outfitter, are more amusing to read than experience. Mattresses that "will go in lumps," and sheets that "won't tuck in," are not pleasant accompaniments of a long sea voyage. Details as to one's diet, and a short account of objects of interest on the voyage (which latter we think might with advantage have been lengthened) are added; and in the last chapter a few hints to the new arrival as to hotels and boarding-houses in the principal towns of the various colonies, will be found very useful in a country where, as Mr. Brown tells us, people are too independent or have something else to do than to stand at the pier and "tout" every fresh arrival.

Mr. Brown has wisely given a capital map of Australia, and has also appended an interesting table, supplied to him from the Emigration Board, showing the small number of accidents which happen to ships in the Australian trade.

EXPERIMENTAL RESEARCHES ON EPIDEMIC CHOLERA.—In a memoir presented to the Academy of Sciences, M. A. Baudrimont asserts the following conclusions: 1 that in cholera the albumen of the blood is transformed into diastase, and is found as diastase in the dejections; that the presence of diastase, and also of a matter analogous to yeast, is remarkable as representing the two products successively formed, at the expense of albuminoid matter, during germination and fermentation; that, as there is a great resemblance between the alvine dejections in cholera and the pancreatic juice, may it not indicate that cholera is due in great part to a hypersecretion of this fluid, and that it is principally by the canal of Wirsung that the choleraic fluids and the matters they hold in solution pass into the intestine?—*Gazette Médicale.*

WEDNESDAY, JANUARY 31, 1866.

MEDICAL REGISTRATION.

WE cannot wonder at the dissatisfaction and even indignation which is now universally expressed at the hardship of Medical Registration, and we are not surprised that many practitioners have declined to pay the fee demanded of them for the privilege of having their names inserted on the Register. However small the sum of five pounds may be considered by some of the aristocracy of the Profession, its payment presses very heavily on the resources of many of the poorer members, more especially when it is levied in addition to the charges made for diplomas or licences to practise. We understand that many of those who have omitted to register have done so on principle, and that they are prepared to take the consequences, whatever they may be, of such a course.

The feeling to which we allude is now becoming so general, that it is worth while to inquire what are the advantages of registration, and what the disabilities involved by its omission. Those who refuse to register point with no small degree of excusable bitterness to the host of uneducated and half-educated pretenders to medical science who swarm in every part of Great Britain, and who are not only unmolested by the law, but are actually protected by it, and who are daily and hourly wresting from the hardworking and honest practitioner his legitimate gains. What, says the latter, can be the use of paying a pretty heavy fee for a registration which confers no advantage whatever and offers no protection? Why should I pay twenty pounds for one diploma and fifteen for another, and then five pounds more for the privilege of registration, when A or B who lives next door to me, and who is undermining me in my practice, has no diploma or licence at all, and snaps his fingers at the provisions of the Medical Act?

Now this reasoning is very just, and it is by no means easy to refute it, and indeed in the present state of Medical law and practice, the attempt would be a hopeless one. The fact is, that Medical Registration, with its accompanying penalty of five pounds, is a perfect farce, except so far as it brings money into the coffers of the Medical Council. This body is now so well convinced of the unsatisfactory working of the Medical Act, that its members are endeavouring to press upon the Government the necessity of amending it; and we think they would do well, in case their efforts in this direction are unsuccessful, to resign their appointments, by which step matters would be brought to a crisis, and the Legislature would be compelled to interfere. At present it is notorious that Sir GEORGE

GREY has no sympathy with the Medical Profession, and that he is quite indisposed to take any measures to redress the grievances which press upon our body, and private members of the Houses of Parliament are unwilling to take the initiative in any proposition which is not likely to be supported by the Government.

An attitude of passive resistance on the part of the profession is therefore not to be condemned, but rather encouraged; and, if the supplies were withheld by those who are entering on their professional duties, the energies of the Medical Council might possibly be further aroused, or, as we have just hinted, they could resign their appointments.

The Medical Act, as it now stands, is a perfect delusion and a sham, so far as the majority of Medical practitioners are concerned. They enjoy no privileges whatever by its operation, and if it were repealed they would be conscious of no difference in their position. Education and honesty of purpose are now opposed, in the field of practice, to ignorance and dishonesty, and the latter pair of qualities are triumphant. Quackery is as rampant as ever, and Medical titles are impudently and unblushingly assumed in order to delude the public, and no law has yet stepped in to punish the offenders. The Medical Act has made no difference as to the estimation in which legitimacy and quackery are respectively held by the public, and the Medical Council have repeatedly declared their helplessness to assist the Profession in the vindication of its rights. If, therefore, the present state of things is to continue, it will be just as well to save the expenditure incurred by the working of the Act, and leave the Profession to protect itself in the best way it can. The machinery has evidently now come to a dead-lock, and the Legislature and the Government must determine whether any efforts are to be made to set it again in action.

THE SICK POOR IN WORKHOUSES.

THE crusade against the present Metropolitan Workhouses is still actively carried on by the general and medical press, and people are horrified at the details set forth by the amateur tramp who passed the night in the casual ward of the Lambeth establishment, and subsequently published his experiences in the *Pall Mall Gazette*. There is something almost amusing in the discovery which appears to have been suddenly made as to the condition of the sick and the infirm in the London Workhouses, although all the facts now made known have been long familiar to the officials, and have repeatedly formed the subject of remonstrance on the part of the Medical Officers. One workhouse, the Islington, is actually announced as about to move its quarters, the present building to be demolished, and another to be built elsewhere; but as the trustees have promised this step for more than fourteen years, and only renew the promise whenever public indignation or the threats of the Poor-law Inspectors rouse them into

a temporary activity, we do not believe the report. St. Martin's *in-the-Fields* (*lucus a non lucendo*) is actually coming down, the ground having been purchased for the National Gallery; and the Clerkenwell and Bethnal Green buildings being utterly condemned as unfit for their purpose should follow as soon as possible. But it is not only the buildings which ought to be remodelled, but the whole system of Poor-law management, so far as the sick and infirm are concerned, ought to be revised, and the Medical Officers ought to be placed in a more independent position, so as to do their duty to the unfortunate persons placed under their care. We hope that the good time for this "consummation so devoutly to be wished" may really soon be "coming."

MEDICAL GOSSIP.

SINCE my last letter, Mr. Editor, subjects of interest have been somewhat rare. The sudden appearance of winter after its coquetting with us for weeks put London completely out of gear for several days. Had the meteorologists foretold that on waking one morning Londoners would have found their beloved streets covered with snow, their busses and other institutions at a standstill, and even telegraphic communication interrupted and the sacred threads lying in the streets, nay, coiling round cab-drivers' heads as they passed, the Londoners would have been only too glad to have appeared in a suitable get-up, regardless of expense, but as the snow came unexpectedly they were, as they always are in emergencies, the most helpless babies, and the great city was a huge mud bath strewn with wrecks of hack vehicles and haunted with clammy cockneys for several days. Surely those having jurisdiction over the streets will have learnt something from this disgraceful exhibition.

In professional circles conversation generally turns to the new baronets, and a feeling of satisfaction seems to be very general at the honour done to Irish medicine and surgery by including the honoured name of DOMINIC J. CORRIGAN in the carefully selected list. Indeed it was quite time that the profession in Ireland should receive some compliment more tangible, though to surgeons hardly more gratifying, than the fact that they have been the teachers of, for a time, reluctant pupils in England and Scotland, and when they came to the chief towns of these countries they might see many distinguished men doing their lessons from the Dublin masters very creditably. I shall only give one instance, the treatment of aneurism by compression. I am old enough to remember when many now using it used to shake their heads incredulously over Dr. BELLINGHAM'S wise little memoir.

Talking of arteries, a policeman, aged thirty-five, was on Sunday morning last showing two persons the way to Bow-street lock-up; one of them tripped him up, the other kicked him; the force of the blow was expended on the poor man's left arm, which he raised to protect his head. When Mr. JOHN WOOD saw him after the accident, the left arm was much distended, there was evidently some injury involving the bones, but its exact nature could not, under the circumstances, be ascertained. The effusion was rapidly extending and had nearly reached the axilla when Mr. WOOD, seeing that there was no time to lose, cut down and tied the brachial artery, a little above the seat of injury, not expecting that this would do more than give time for consideration of what the chances of saving the arm might be. On Monday, after a return of sensation and warmth to the fingers, the skin became mottled and gangrene rapidly spread upwards; it was determined to amputate, but the man sank too rapidly, and died early on Thursday morning. An examination yesterday showed that the osseous complication

was a dislocation of the radius and ulna backwards; the brachialis anticus and the brachial artery were torn completely across. There was a considerable amount of blood diffused among the tissues and along the sheath of the vessel. This case involves many important surgical questions and many "ifs," for if the skin had been injured amputation should have been performed; if the bone had not appeared to be fractured the artery should have been tied at the seat of the injury, say some; others quote a case which appeared very similar to this one, under the care of Mr. MOORE of the Middlesex Hospital, in which all varieties of treatment were suggested in consultation, and at last it was decided to leave the patient alone; he recovered without a bad symptom. But then who can swear that the vessel wounded was more than a branch from the main trunk. Talking of police cases, as I passed Bow-street this morning there were notices appended outside relating to no less than five persons found dead last night. I asked the policeman whether they generally had so many, "we average five to six, sir, but some mornings there are none."

The stormy weather has one advantage—namely, driving the students under shelter; untempted by ice, they have worked most manfully in the dissecting-rooms. Nothing could, perhaps, be better than the present method of teaching human anatomy in the larger London schools. Mr. NUNN, of the Middlesex Hospital, has long been distinguished for his powers of generalizing anatomical details and teaching principles rather than dogmas. At the King's College School a man must be a good deal worse than a block-head who fails in any examination where anatomy is required. Let me describe: At nine a.m. Professor PARTRIDGE lectures; students, perhaps, think that he lingers too long over the bones, but they find that by Christmas they know them; can tell carpal bones right from left, and are practical osteologists. Mr. PARTRIDGE does not think it beneath his dignity to be quite intelligible and sometimes very amusing, though woe betide any one who neglects his work. Mr. WOOD, the demonstrator, whose eminence as an anatomist and practical surgeon is universally acknowledged, superintends the dissecting-room, gives public demonstrations and examinations on alternate days; each student is examined on his part twice, those who are preparing for the University of London on regional anatomy, those for the College of Surgeons, in accordance with what is likely to be asked of them there, but irrespective of all examining boards, each man is frequently examined on the numerous subjects in the rooms by Mr. BELLAMY and Mr. ROBINSON, also demonstrators. Special dissections are also daily carried on in an adjoining room by the prosectors, superintended by Mr. PERRIN. There is also a class of artistic anatomy, and the minute structure is taught and exhibited by Professor BEALE. The arrangements are such that teachers are at call during the whole day, so that the student is never left unassisted, and dissecting is not done in a perfunctory manner. It would, of course, be far more simple to begin by teaching the simplest forms of animal structure, and gradually ascending to man; but so long as examinations hang, as they do now, over the heads of the innocents, it is idle to hope for a change. Introductory lectures tell the student he must read three hours for each lecture. At the rate of four lectures a day, that comes to sixteen hours, leaving eight for locomotion and rest!

There is to be presented a testimonial to Sir WILLIAM FERGUSSON, but no one yet seems to know what it is to be. Such things in this country generally resolve themselves into either eating and drinking, or things to eat and drink off; both afford an opportunity for speech-making and glory to the speech-makers, the unfortunate listeners having been rendered as insensible as possible to their sufferings. After the manner of Eastern nations, why should they not

quietly accumulate a sum of money sufficient to found a surgical prize, open to students of all countries and schools. It need not be a costly one, and would surely be a better compliment than the hackneyed dinner and the fulsome speeches, which coming from younger men, are so apt to resemble expressions of gratitude for favours about to be received.

Dr. PROTHEROE SMITH has been made a Knight.

I am glad to perceive that there is a feeling of regret at Mr. SYME being passed over (if he has been) for surgery. No one has during this or any other century done more to make Surgery one of the exact sciences, or had a greater influence over his professional brethren in all parts of the world. EARL RUSSELL has nothing to do with professional squabbles, and these once lost sight of, who has earned a prouder place as a scientific and practical surgeon than the clinical professor of Edinburgh.

MEMORANDA OF THE MONTH.

IT will surprise some of your readers to know that vaccination of cattle is taking place so generally all over the country, that lymph for our young patients is only obtainable with great difficulty, and the Privy Council has issued strict orders that it is only to be distributed for human vaccination. One enterprising surgeon in this metropolis, who has heretofore sold three tubes for half-a-crown, now obtains that sum for one, with every prospect of obtaining a higher amount.

One thing appears pretty certain, that those owners who have had their cattle vaccinated have been very successful in preserving them; the experiments of Mr. Tolemach, as reported in the *Times*, your readers have no doubt seen, as well as those by Drs. Belyse, Lord, Vaughan, and Mr. Matthews, out of several hundred cases vaccinated by two of those gentlemen, the operation was successful in nearly 90 per cent. So satisfied are the Cattle Plague Commissioners of the value of the experiments that they have just issued official instructions, drawn up by Mr. Ceeley of Aylesbury, a member of the profession, as to the proper manner for carrying on the experiment.

We have just had another death from the administration of chloroform in St. Mary's Hospital, Paddington.

There are so many other sources from which information is acquired, as to movements in Lincoln's-Inn Fields the dissatisfaction felt in the University of London at the neglect of botany and zoology in provincial schools, the small gossip as to sergeant-surgencies or titles we prefer rather to speak of recent meetings of great importance on Irish medical taxation—on the medical aspect of the "Infanticide" question, and the curious proposal of Parliament to throw overboard all medical evidence in such inquests. We would linger about hospital wards or scan the peculiarities of meetings of the Pathological, Medico-Chirurgical, or such Societies, or note the increase of medical coroners in Great Britain, worthy of imitation in Ireland! There are murmurs as to Scottish influences in excess at "court" as to titles, but medical students look upon it as a beautiful retributive law, that the most direful and dreaded of examiners at Lincoln's-Inn Fields has not given up his Sergeant-Surgency or been made a baronet.

We would see what reform is possible in the "red ticket" system, judging by the better plan of Poor-law administration now in England, due to Mr. Griffin. In France and Belgium the principle of Irish workhouses is considered by the Emperor all a mistake, and analogy may guide us here; the medical arrangements for the sick poor

in France are far better. We must have the subject, however, broadly and thoroughly examined, not in bits and scraps, to suit this or that poor-law official. Irish rate-payers pay all the tax, so they do not love the doctors; but in England the larger part comes off the Consolidated Fund, and the workhouse doctors are, to some extent, independent.

Amongst the leading subjects discussed during the week in the medical circles have been again the vexed question of the nature of the cattle plague. It has been set forward rather in form of hypothesis as agreeing with the worst forms of signs of rinderpest than from any new demonstration on the pathology of its disease, that it is simply small-pox. And even small pox in the cow, according to the experiments of Ceely and others, was a mild and harmless affection, giving rise rather to vaccine.

It is said also if small-pox was transmissible to oxen, we should have it very much oftener in England than in this isolated irruption or outbreak of disease and diseased animals from foreign ports. It is a curious fact bearing on this view of small-pox and rinderpest being connected or identical, that in nomadic tribes in the East, living very much amongst their cattle, Arabs, Tartars, &c., that small-pox is very seldom or never seen, while in China, and dirty Chinese towns, almost every second person we meet is badly pock marked and vaccination neglected. Amongst such nomadic tribes the children from time immemorial have probably become spontaneously vaccinated or preserved against variola.

The week has been busy—with debates on the often-vexed story of the cure of curvature of the spine, a disease pleasant to the ears of instrument makers; with lectures Lettsomian on various painful affections of the fifth nerve; and with increasing alarm and pathological experiments on the cattle plague, the medical schools have regained their normal appearance of work. As the holidays have passed away, Mr. Paget has resumed his admirable series of early morning clinical lectures—somewhat as early chapel at Oxford, and not much more delightful to our junior friends. The new journal, though unavoidably delayed, has made its way into the hospital libraries, and is much admired.

It is probable that cattle plague, though an exanthematous disease, is neither typhoid nor variola, as held in turn by the same authority. The veterinarians are familiar with small-pox in sheep and rinderpest in sheep, and they are not at all the same; nor is the idea more happy, perhaps, that the latter disease is due to entozoa, as Dr. Cobbold has pointed out for such entozoa, if entozoa at all, were found in healthy cows, and other animals. As Lord Bacon well says, however, we must abide by the verdict of experiment, and to conquer nature we must be obedient to it.

The well-worn monogram on London hospitals, "supported by voluntary contributions," at once the glory and the shame of our metropolitan institutions, has had lately a suggestive commentary in the fact, that in the French coming budget the sum of £66,000 has been placed to the credit of the medical and surgical wards of the Paris hospitals in the last year, as collected by a Government tax on opera tickets and music halls for that purpose! Much agitation have we for "village hospitals" in England: might it be unprecedented if the large sum obtained for quack medicines were appropriated by Mr. Gladstone in some such useful manner as the tax on

opera tickets across the channel? The French plan is, indeed, one of compensation in the best sense of the term. For the rich, of their marvellous superfluities, scarcely know what to do with their money in operas, concerts, horse races, &c., and the poor scarcely know where to turn for good medical relief when struck down by disease, many of the latter, seamstresses, servants, wash-women, &c., being worn out in the service of the former. Nothing can be fairer than this system of compensation. In commenting on the small dole to Dublin hospitals by Parliament, it is too often kept out of view that the two chief London hospitals, St. Bartholomew's and St. Thomas's, are supported in the same manner, by large funds accruing from capitalised income, the result of the sale of tracts of land by Parliament to these institutions. It is the dozen and one smaller hospitals that are supported by voluntary contributions.

A new step having been taken, that of placing the Fire Brigade of London under the Board of Works, three medical officers were elected last week. There was a large attendance of competitors, not less than twenty-six for one division, to which Mr. Propert was appointed. This board (the paymaster of the doctors) had something like half a million of money on hands at last return of the treasurer.

A discussion of no little moment continues in the hospitals, as to whether recent researches on cancer do not point rather to the local than the constitutional nature of this fell malady; at the Middlesex Hospital Mr. Moore and Mr. de Morgan, under the belief of the local origin of the disease, have been of late months advising early removal of cancer of the breast, to be followed by free use of chloride of zinc or such caustics to all the adjacent tissues, so as to destroy utterly those fatal cancer-cells that otherwise, in too many instances, are merely absorbed. After ordinary amputation, the new puncture has, up to the present, proved very satisfactory, and all surgeons interested in such cases would do well to read the paper by Mr. de Morgan in the current number of the *British and Foreign Quarterly*, bearing on the treatment of cancer; there seems to be much reason to fear indeed that in common amputation the open mouths of vessels absorb too readily such cancer germs. Of other points of new practice in the hospitals perhaps we may here cite the continued success of the plan in ovariectomy of dividing the pedicle and adhesions by *actual cautery*. Of eighteen such cases, all of which we have watched in the practice of Mr. Baker Brown, sixteen have recovered, and even in these two fatal cases nothing could have saved them short of a miracle. One curious case of enormous size proved to be a multilocular ovarian growth, apparently thrown off when small from the stroma of the ovary, broadly adherent to the omentum by large adhesions, free, in fact, in the peritoneal cavity, without attachment by pedicle or otherwise to the ovaries, both of which and uterus were normal in character. The adherent growth was very large, has been carefully examined, and proves to be such an ovule. The woman has made an excellent recovery.

An interesting fact of moment to botanists, has been brought before the Geological Society. It is said that *stigmaria* under nearly every bed of coal prove that the material of the coal was accumulated by growth *in situ*, while the character of the intervening strata proves the abundant transport of mud and sand by water; nothing

more. So that we have here, in fact, the key to the formation of such beds as those in Kilkenny in Ireland and Newcastle in England.

Correspondence.

CATTLE DISEASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As the rinderpest is a disease which affects more or less the entire population of this kingdom, I have ventured to address the Privy Council on the subject, and as the letter may be of interest to your readers, I beg to enclose you a copy.—I am, &c.

RICHARD GRIFFIN.

Weymouth, 20th January, 1866.

"12, Royal-terrace, Weymouth,

"January 16, 1866.

"MY LORDS AND GENTLEMEN.—Should the experiments now being carried on by the many able men engaged on the subject prove that the rinderpest is small-pox in a most malignant form, I assume you will take immediate measures to prevent, if it be possible, the spreading and continuance of this most frightful murrain. For this object it is that I venture now, most respectfully, to offer the following suggestions:—

"In the first place, I would not allow any of the bovine tribe to travel or be removed from one parish to another unless the fields of the owner of the animal be situated in two parishes, until it be satisfactorily proved that the animal had been successfully vaccinated, or was unsusceptible of vaccination, or had the small-pox in the natural way; at least one month prior to such removal, and had not been in contact for a like period with any animal that had the disease now called or known as the rinderpest, in proof of which a certificate should be produced from a medical man or a member of the Veterinary College as to the former, and the owner of the animal should be compelled to make a declaration before a magistrate as to the latter.

"In the second place, it should be made compulsory that all calves should be vaccinated before they are three months old, a time sufficient to allow all those not intended to grow up to be killed as calves. In order to facilitate this measure and do away with any objection by the owner to vaccination on the plea of expense, let similar arrangements be carried out as are now in force for vaccinating the human subject, and the parish or union will then have to defray the expense, it is now I believe a parochial charge, and if the district medical officers of unions, parishes, and incorporations would consent to become the vaccinators, then you will at once have a staff in England and Wales of over three thousand medical officers, fully competent, with a few general instructions, to carry out the plan. A similar course might be ordered for Ireland and Scotland.

"In the third place, it should be made a law that no foreign cattle of the bovine tribe should be allowed to be imported into the United Kingdom, unless proof be given that they had been successfully vaccinated at least one month prior to their exportation to this country. The result would follow that those engaged in the traffic would be compelled to vaccinate their animals, and thus we should be an example to foreign nations, which would be highly beneficial to them.

"In order to facilitate the proof of successful vaccination, not only should a certificate be given by the vaccinator of each animal, but he or the inspector should be furnished with a pair of cutting nippers, of a peculiar shape, by which he should remove a portion of one ear, and without that mark no beast of the bovine tribe should be admitted into any markets or taken by any railway. The payment for vaccination must be higher than that now paid out of the public funds for human vaccination, as the labour would be considerably more. The lymph to be used should be taken direct, if possible, from an animal, and not from the human subject, as the latter will not always succeed. A payment should be made for the vaccination and an extra sum for the inspection and granting the certificate, without which certificate no animal should be allowed to be removed with its skin on from one parish to another without a penalty

attaching to both purchaser and seller, excepting either should turn informer, when he should be exempt.

"If these or similar regulations be carried out, I feel confident, should the rinderpest be proved to be small-pox, that in the course of a very few months the disease would cease to exist in the United Kingdom, literally for want of animals susceptible of it, as, of course, all the present animals, as well as calves, would be allowed to be vaccinated at the public expense.

"Means must be provided for the supply of lymph, especially at first starting, and this can only be done through the medium of a Government establishment with a proper staff of inspectors.—I have the honour to be, my lords and gentlemen, your obedient servant,

"RICHARD GRIFFIN, J.P., M.R.C.S., and L.S.A.

"The Rt. Hon. the Privy Council."

ON THE TREATMENT OF RINDERPEST, AND ON THE NATURE OF ITS ERUPTION.—FAILURE OF VACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Important Letters from John Balfour, Esq., I.G. (retired), Inspector of Rinderpest for the County of Forfar.

DEAR SIR,—I have at last some information to give you regarding my plan of injecting chlorate of potash hypodermically in rinderpest. In the first instance it was tried on three animals (year old) at Arrat's mill; one recovered and two died. I was inclined to suppose that in this instance the application had not been made sufficiently often. In the second instance, three calves (year old), at the farm of Rosemount, were injected regularly, and the result is that two of the three have recovered. The farmer remarked that the two that recovered had both sweated very freely; this is, as you may perhaps know, one of the critical terminations of the complaint, and generally a favourable one. I cannot but hope that the remedy is a promising one. I believe you are aware that the syringe I use (made by Young, Edinburgh), holds exactly one ounce. With it I inject under the skin of the ribs one ounce of distilled water, holding in solution five grains of chlorate of potash, night and morning, from the commencement of the attack till the animal gets the turn. Careful nursing and proper stimulation being of course never neglected.

One of my subordinates, assisted by a medical man in Montrose, tried the effect of saline injections into the veins in two animals, both far gone in the complaint; one died, the other recovered. They injected six quarts of water at the temperature of 100° F., in which half a pound of table-salt had been dissolved. This seems also a somewhat promising result; but the operation is not so easily performed as mine is, and is not so free from any risk of injury.

I have lately noticed more symptoms of excitement before the disease has fairly set in. In the courts feeding beasts get restless (*fractious*), horning each other. Queys often want the bull a day or two only before becoming fairly ill, and cows occasionally show marked excitement (become *raised*).

As to the natural cow-pox, Mr. Sanderson, Keiriemuir, states that he has had much of it of late, many of the milkers having applied for something to heal the teats. He cannot be quite positive, but he believes that many which had the cow-pox died. He showed me, however, on the 18th at Bow of Ballanshow, seven cows, which all had natural cow-pox within the twelvemonth, all of them suffering from rinderpest, but all having it mildly, and on the teats and udders of all of these cows there was an eruption exactly resembling small-pox. This was pointed out by the girl who milked them; the teats were hot and inflamed.

At Brechin, six cows of Provost Guthrie's, which all had natural cow-pox last summer, took rinderpest, four died, and two recovered. So much for facts. Since the 18th I have

examined the udder of every affected cow, but have come across no more eruption. When an eruption is seen on the neck or rump, it is scurfy. I have never, but in the one instance, seen anything like pustules.—I am, yours, &c.

JOHN BALFOUR.

[Just as the above was written we were favoured by a call from the Forfarshire Inspector with the not unexpected information that vaccination had failed to exercise any prophylactic power whatever. The facts are simply these: the Earl of Earlie has had several of his cattle vaccinated successfully, the course of the disease, as described, having been regular, and the scabs, as seen by the Inspector, large, handsome, and apparently true cow-pox scabs. After recovery was complete, and the animals as well protected as vaccination could make them, one protected and one unprotected animal were sent to an infected byre. Within a week both had taken the disease, and when the Inspector saw them the vaccinated beast was the most seriously ill of the two. A full report of the experiment and its failure will, however, be made by the Earl to the meeting of the Justices at Forfar on the very day this is published.—ED. MED. PRESS AND CIRCULAR.]

On requesting further particulars as to the nature of the eruption termed cow-pox, as well as to that of the pustular eruption of rinderpest, the following reply was received.—

Forfar, January 24th, 1866.

DEAR SIR,—I perfectly understand how much depends upon the certainty of the eruption termed cow-pox being real variola vaccinia. I am perfectly certain that some of the so-called cases could not have been true instances of that, for one girl declared that her cows had the "pock" every year! But in some instances, at least, there is no doubt that it was the correct thing. Mr. Hampton, V.S., of Arbroath, described it to day quite correctly as an unilicited vesicle surrounded with a rosy areola, and infecting the hands of the milkers when chapped. I have not, however, seen any of these cases myself, so can say no more about them. As to the eruption in rinderpest, there is often *none*, the udder and inside of the thighs and forearms being quite clean and smooth. In the most marked cases the teats are swollen and hot; the pustules which I saw were conoid and pretty mature, in fact just commencing to crust. The eruption observed upon the neck and loins is always scurfy and without any distinct crusts. The more I see of the complaint the more I find it necessary to watch symptoms. The head, lungs, kidneys, and bowels are all and each of them liable to be involved. The first is rare, and the cases generally do well; the second is very serious, and generally fatal; the third serious, but not so fatal as lung complication; while the fourth is very common, more or less diarrhœa existing in almost every case, and is generally easily manageable. Free perspiration is a very common and favourable symptom.—Yours, &c. JOHN BALFOUR.

[Mr. Balfour, a retired Inspector-General of her Majesty's Indian Medical Service, has been engaged for nearly three months in inspecting the rinderpest in the county of Forfar, perhaps the largest cattle breeding county in Scotland. He has, of course, seen an immense number of cases (upwards of 8000 cases having occurred in this county), and any opinion of his is deserving of the utmost attention. It will be seen that, without speaking dogmatically upon points in regard to which he has had no personal experience, the whole weight of his experience is against the idea of rinderpest being essentially an eruptive exanthem, and also against the idea that the natural cow-pox is any preservative from an attack of that virulent distemper. Several crusts of the best marked cases, which he has had the kindness to trans-

mit to us, are flat and scaly, and much more allied to the scabs of herpes than to the round horny buttons of cow-pox. Such as they are, however, they are at the disposal of any gentleman who may wish to experiment by inoculating with them. Is it a common thing for variola in any class of animals to terminate critically by perspiration?—*ED. MED. PRESS AND CIRCULAR.*]

DR. CRISP ON THE CATTLE PLAGUE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—To prevent any mistake in the report of my remarks at the Pathological Society on the cattle plague, so called, I send you the full account, which you can curtail or omit altogether as you desire. My excuse for this is the great importance of the matter at the *present juncture*, and the fact (as far as I know) that two animals have not been before inspected at the same time at the early and remote periods of the disease.—Yours obediently,

EDWARDS CRISP, M.D.

42, Beaufort-street, Chelsea,
January, 16, 1866.

Dr. Crisp exhibited some fresh preparations taken the day before to illustrate the pathology of cattle plague in its first and later stages, in reference to the identity of this disease with small-pox. They consisted of a part of the fourth stomach, a portion of the ilium, and parts of the skin of a cow that was killed thirty hours from the first appearance of the plague, and examined by Dr. Crisp immediately after death. There was no appearance of eruption on the skin, but one irregular-shaped red spot was present on the inner part of the lower lip, and the subcutaneous layer of the nose was much congested. The endocardium did not present the usual appearance of red marking and staining, from extravasation of blood, described by Dr. Crisp in his first communication at the Society, October 17th. The lining membrane of the vagina was much reddened, and under the microscope presented the mottled, spotted aspect of the skin in scarlatina. The mucous membrane of the fourth stomach was reddened, and in various parts small spots of a deep lake colour, varying in diameter from the fifteenth to the fifth of an inch, were present, the epithelium being removed. Some parts of the bases of the intestinal ridges were intensely red. On the same day, January 14th, another cow that Dr. Crisp had seen when labouring under cattle plague was killed seven weeks after the first appearance of the attack. She had the disease very severely, suffered much from diarrhoea (which was checked by opium and sulphate of copper), and she passed bloody urine and a portion of the lining membrane of the bladder. She was much emaciated, and although the result of the examination showed that she would probably have recovered it was thought better to kill her. No trace of eruption was visible on any part of the skin examined. The epithelial lining of the three first stomachs was entire. Large brick-dust coloured patches were present in the fourth stomach, but over the greater number of these the epithelium had been restored; but in a few there was partial abrasion. The intestines were not mottled externally, and those parts of them examined had recovered their normal state. Patches of a brick-dust colour were present on the prominence of the left cardiac ventricle, but they had lost the dark appearance they usually present in the first stage of the disease. A fœtus weighing about eight ounces was found in this cow in a partially decomposed state. Dr. Crisp said he wished that he could agree with Dr. Murchison as to the identity of this disease and small-pox. There might be some resemblance, but he could discover no identity either in the symptoms or morbid appearances, and he anticipated that no good would result from inoculation with small-pox or vaccine matter. He had seen several cows that he had reason to believe had had cow-pox, and yet several of them had died of the plague, and others had had the disease very severely. His experience

told him that the only plan to get rid of the disease was to stop all movements of cattle, sheep, and pigs, kill and bury all affected, and compensate the owners. There was one important fact in connexion with this disease that he had alluded to in his first communication (October 17th) that had an especial bearing upon the identity of this plague and small-pox. Men employed in slaying diseased animals had often an eczematous eruption upon the arms and thighs which sometimes continued for three or four weeks. It evidently arose from the acridity of the virus, for these men were in the habit of placing the knife between the thighs, and hence the presence of the eruption on these parts. It first appeared as a red pimple, then slight vesication and desquamation followed, with intense itching. Dr. Crisp said he had had it on his own arm.

MEDICAL REGISTRATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—What have Registration and the Medical Act done for the members of the Medical Profession up to the present time? I think that all Medical men may justly and conscientiously reply, by saying, that neither one nor the other has done anything really beneficial to promote in the smallest degree the welfare of the Profession at large. Let those who may be disposed to say that the above is a falsehood, bear in mind that quacks of all sorts flourish now as much or even more than they did when Registration was unheard of. Some years ago, when the student had obtained his diploma and become a surgeon, &c., he could enter the Army or Navy, take a Poor-law appointment, or practise privately, sign certificates, give evidence in court, and make his claim in court likewise, if necessary; but now, forsooth, he cannot do so unless he be registered—in fact, he is as well off, legally considered, whether unqualified or unregistered.

Registration, on the one hand, has summarily and arbitrarily taken five pounds out of the Medical man's pocket, and, on the other hand, the Medical Act has not found him in return five farthings' worth of protection against the inroads of hordes of knaves who attempt to do his duties, calling themselves herbalists, bone-setters, &c., to evade the law. As the Medical Act stands now, every rogue may practise Medicine and Surgery, only he must not assume the title or degree of surgeon or doctor, &c. The bone-setter, herbalist, medical botanist, and galvanist, may laugh in the face of the duly qualified practitioner who is registered, and say, "I am as good as you if the public think so, and will employ me! There is no law to prevent me from practising medicine, surgery, midwifery, and pharmacy, only I must not call myself doctor." Alas! it is only too true. On reading over the Medical Act one would think its framers intended to leave a loop-hole by which every quack and would-be doctor could escape and evade the law. Let Clause xl. remain as it is. But enlarge the present Act by the addition of three more clauses—namely:—

Clause 1.—Any person or persons, male or female, giving medical or surgical advice, performing surgical operations from the extraction of teeth upwards, or attempting to practise medicine, midwifery, or surgery, without a medical or surgical diploma, to be fined according to the gravity and frequency of such offence or offences.

Clause 2.—Any person or persons, male or female, rendering medical or surgical aid, giving medical or surgical advice under cover of charity or as amateurs, either directly or indirectly, that is prejudicial or detrimental either to the social welfare or pecuniary interests of any member or members of the medical profession, to be fined according to the gravity and frequency of their offence or offences.

Clause 3.—Exceptions to be made under Clause 1:

First—In cases of midwives practising under the supervision of any medical man.

Secondly—In cases of pupils, assistants, and students practising medicine and surgery in all its branches, for the benefit of their masters and principals, or for any hospital or dispensary to which they may be attached.

Exceptions under Clause 2 to be made for any persons rendering either medical or surgical aid in cases of sudden illnesses, or injuries from any accident whatever, until proper medical assistance can be obtained.

Now, if such were the Act, then quacks could not shelter themselves under the law and say: "I do not call myself surgeon or doctor." That excuse would not avail them; they are not fined for calling themselves doctors and surgeons, but for attempting to do the doctor's work without the doctor's diploma. Again, I repeat, if such were the Act, then would the bone-setter have to find some other employment; the herbalist and galvanist must follow the same example; the proprietors of the Anatomical Museums, &c., must exercise their wits and gain a living in some other manner than by preying upon the credulity of John Bull.

If such were the case, then would the public be saved from falling victims to quackeries of all sorts; and, what is of quite as much importance, the Profession would rise in every one's estimation when the said public are shown and made to know the difference between the real doctor and the unprincipled knave who assumes the doctor's title, but who is proved to be what he is, a rogue and a vagabond, who only feeds upon the utter ignorance and extreme gullibility of by far too great a majority of the British public, to the great injury of all duly qualified medical men who have obtained their diplomas at a great cost of time and money and wear and tear of mind and body.—Yours, &c.,

HENRY W. WILLIAMS, L.R.C.P. Edin.

Guildenbury, January 22, 1866.

EDUCATION AND TRAINING OF IDIOTIC AND IMBECILE CHILDREN.

THE results obtained in the institutions established in England, Scotland, and elsewhere, for the education and training of the idiotic and imbecile, have fully established that children so afflicted are capable of having their condition greatly improved, and that a very large proportion of them can be so taught as to enable them to take a place in society, and acquire habits of industry and application so as to support themselves instead of being burdens on others. The experience gained in these institutions has also shown that many of the children, who have come there in a state of utter ignorance even as to the existence of a God, have had their minds awakened to a consciousness of His love and beneficence, and to the elementary truths of religion.

It is proposed to hold a meeting, on 1st February, in Dublin at Charlemont House, Rutland-square, at three o'clock, to consider the propriety of establishing an institution for the training and educating of idiotic and imbecile children.

The proposed institution is intended to extend these benefits to the idiotic and imbecile children of Ireland, for whom nothing of the kind has hitherto been done, though according to the last Census there are 7033 idiots in Ireland, and more than one thousand of them at an age when good hopes might be entertained for improvement in their condition by properly directed efforts.

The care of the idiotic is necessarily expensive, and the arrangements for carrying on their training and education efficiently are such as to require spacious accommodation, workshops and grounds; and as success depends, in a great measure, on the completeness of the arrangements, it is desirable that an institution should be erected specially for the purpose, the probable expense of which may be estimated at from £10,000 to £20,000, according to the number of children to be admitted.

In England and Scotland the founding and maintaining of such institutions has been left to private efforts, and on the humanity and benevolence of Irishmen it must depend whether Ireland is to remain almost the only civilized country in the world in which no provision has been made for improving the condition of her idiotic and imbecile children. It is hoped the cause will be deemed worthy of an earnest, zealous, and liberal support.

HEALTH OF TOWNS.

By HENRY MAC CORMAC, M.D.

I READ with very great interest Dr. Mapother's very able address "On the Health of Towns" delivered at the recent meeting of the Dublin Statistical Society. His excellent remarks on which it is not, however, my intention to comment at any length, are suggestive of many things. It strikes me that his death-rates, I do not mean relatively but absolutely, are lower, much lower, than the reality. He dwells on the sinister fact of the death-rate, generally, being so much higher in town than country.

My object, however, in these remarks is not to insist on the ordinary, and very important topics which Dr. Mapother's address has embraced, but on some others to which he has not much if at all adverted, and which indeed are left, mainly, in abeyance in most sanitary treatises and discourses. To these topics, then, without further preface, I shall now at once address myself.

A great deal has been said about nuisances and the inspection of nuisances. But there ought, absolutely, to be no nuisances to inspect. So long as there are nuisances, so long will there be stench, so long will there be disease. But how, it may be asked, are nuisances to be avoided. In the first place, all towns, great and small, every portion of them, ought to be swept daily, and the accruing filth then and there removed, from end to end. Less than a daily sweeping, say a little before daybreak, will not suffice. And what is the use of sweeping, if the dirt be left to spread again?

Sewers should be abolished. There ought, indeed, to be no sewers. They but form continuous cesspools, never ceasing sources of poisonous exhalations. Of course, the rain water will need an outlet. But if the street dirt be swept away, there need be no sewers to hold the dirt. As for house excreta, these ought to find reception in the porcelain lined tanks of earth closets. Earth closets ought to replace water closets. Dry earth, even wet earth, is a complete disinfectant for feculence of every kind. The tanks might be emptied every week into ambulatory tumbrils which should convey the excreta out of town. Phenic or carbolic acid, if furnished cheaply enough, might also, in some cases, be used as a disinfectant. Phenic acid, furthermore, kills all parasites. The corporations of towns, indeed, ought to see that every household, however humble, was provided with a sufficient earth closet, adequately ventilated, and sufficiently apart from the living apartments.

All animals, employing preferably the painless mode of extinguishing life by immersion in carbonic acid, should be slaughtered in the country. It is a perfect scandal to slay animals designed for food in towns entailing, as the practice does, the consequent abominations of offal, gore, and other reeking uncleanness. But animals are not only put to death in towns, but in many different portions of each town, to the multiplication of all the evils and all the foulness which so undesirable a practice in the midst of densely peopled neighbourhoods necessarily entails.

A sufficient water supply is of very great moment. I never drink water myself, unless filtered, at least, I prefer it filtered, and endeavour always when I have the alternative, to obtain it so. What is good for myself should be good for others. Not long since, a tumbler of drinking water was handed to me, a tumbler of water which, when held between the eye and a gas flame, was simply alive with animalculæ. We are not too well conversant with the actual conditions and requirements of minute animal

life, but there can be no doubt, I think, that parasitic organisms find their way, by means of drinking water, sadly too often into the economy of man and brute. The eggs of tænia, it is said, have been found in ponds, supplying houses, in England. Vogt, in Germany, in his "Physiology," mentions another form of food supply, a fluid being the vehicle, in which, he affirms, the eggs of tænia gain admission.

The state of Iceland, with regard to tænia, at the present time, is very serious indeed. The trichinæ plague still afflicts Germany, and may extend to us. Certainly, all drinking waters, unless of undoubted purity, ought to be passed through a charcoal or other sufficient filter, or if not, boiled and suffered to cool before being used. The importance of the bath, of personal cleanliness, is so great, as to approach next in importance to the respiration of unprebreathed air itself. Every sufficing provision should be made subservient to it. There ought to be a bath apparatus, were it nothing more elaborate than a basin of water and a towel, adequate for the use of every person, in every household. The necessity, the deep moral meaning and intention, of cleanliness, has as yet dawned very imperfectly on the minds of the people. If they but wash their face and hands, they think it is enough. In the Government Sanitary Reports, I think it was for 1842, a witness in a case at law is cited as swearing positively to some fact trivial in itself, but important as connected with the general evidence. "How can you assume to swear positively to the date of such a trifle," said the lawyer for the plaintiff. "Sir," said the man, "I remember it well, for I washed my feet on that day." I went some distance in a railway carriage, this year, it was in some English midland county. There was a passenger, also a young and handsome man, too, whose feet were a perfect ghastly stench. And, to add to the infliction, he placed them on the empty seat before him. "Do you never bathe your feet," I asked some Irish cabinet-makers lately. They were otherwise decent fellows, too. "Sir," they replied, "We have no time to wash our feet." "No time," said I, "to wash and be clean and, yet, you have time to eat, to drink, to sleep, to smoke, to lounge. Why, you ought to wash every day, you live, from head to heel."

The last serious point to which I wish to advert, a point quite inadequately dwelt upon in sanitary reports and works devoted to hygiene, is the ventilation of rooms, and in especial of sleeping rooms. It is not enough to say, in general terms, that houses and living rooms ought to be ventilated. The stern needfulness of not breathing twice the same air, should be strongly and well enforced, likewise the importance, the unutterable importance, of keeping the sleeping chamber window open at night, in such wise that the air of the chamber shall be as fresh or nearly so as the outer air, and that it shall be simply impossible to respire a second time the air that has already served the purposes of the living organism.

Belfast, Jan. 1866.

THE PUBLIC HEALTH.

THE *Athenæum* remarks that among the subjects to which the attention of Parliament will be most urgently needed, is that of the removal from the metropolis of the large number of dangerous and unhealthy manufactures, which now add much to the already sufficiently great disadvantages of a London residence. The removal of considerable numbers of workmen employed in these trades will directly benefit not only themselves by the comparative cheapness and healthiness of more distant lodgings and supplies of food, but their whole class, by a commensurate reduction of the demand for accommodation and necessaries. Most of these injurious trades are carried on in the most thickly inhabited parts of the town; the bone-grinders, manure-makers, and gas-producers, congregate about Lambeth, Battle Bridge, and Whitechapel. In the first named place the gas-factories, which have been proved to be dangerous by repeated explosions, and, notwithstanding the assertions of engineers, capable of the most terrible effects, occupy a very large portion of the most closely packed district, which, such is

its position, threatens and annoys some of the most important parts of Westminster. Westminster itself has in its very heart a huge gas-factory. A brief motion in the House of Commons for a statement of the quantity of gas which is stored within a circle having a quarter of a mile radius from the Abbey and the Houses of Parliament, will astonish and probably terrify that legislative body, which has so long borne the stench of Lambeth and its bone-burners. The nuisance created by the latter is so great, that in Lambeth Palace it is often needful to close every window to windward. The new hospital about to be built at the foot of Westminster Bridge will be another inducement to procure the expulsion of the filthy trade in question. The Legislature, when enacting that no new premises should be erected in London for the lucifer-match manufacture, took a step in the desired direction, and pronounced a principle which should be extended in its application.

SCIENTIFIC SOCIETIES.

ZOOLOGICAL.—Jan. 9.—A. Newton, Esq., in the chair.—An extract was read from a letter by Dr. H. Burmeister relating to the birds of the family Tyrannidæ, found near Buenos Ayres. An extract was read from a letter by Lieut. R. C. Beavan, containing an account of an excursion recently made to Zwagabon, a remarkable lime-stone rock near Moulmein, with notes on the various animals observed during the journey.—A letter was read from Sir C. W. Dilke, Bart., announcing the occurrence of a Gyr Falcon (*Falco gyrfalco*), in the Holt Forest, near Farnham.—Prof. Owen read a memoir on the osteology of the Dodo (*Didus ineptus*, Linn.). The materials upon which Prof. Owen's researches were based consisted of about one-hundred different bones belonging to various parts of the skeleton which had been recently discovered by Mr. G. Clarke of Mahéberg, Mauritius, in an alluvial deposit in that island. After an exhaustive examination of these remains, which embraced nearly every part of the skeleton, Prof. Owen came to the conclusion that previous authorities had been correct in referring the Dodo to the Columbian order, the variations presented, though considerable, being mainly such as might be referable to the adaptation of the Dodo to a terrestrial life and different food and habits. A paper was read by Dr. J. E. Gray, containing "Descriptions of two new forms of Gorgonoid Corals from Japan and the Cape of Good Hope." A communication was read from Prof. Lilljeborg, containing a systematic review of the class of birds. Mr. Sclater made some remarks on the recent additions to the Society's menagerie, amongst which was particularly noticed a fine young male Gayal (*Bos frontalis*), presented to the Society by the Bahu Rajendra Mullick, of Calcutta. Mr. Sclater read a Report on birds collected at Windvögelberg, South Africa, by Captain G. E. Bulger, amongst which were examples of two species new to science. A paper was read by Mr. J. Gould, describing a new species of Tōnean from Loxa in Ecuador, proposed to be called *Aulacorampus cyanolænnus*.

ETHNOLOGICAL.—Jan. 9.—J. Crauford, Esq., President, in the chair.—The papers read were:—"On the Physical Forms of the Lapps," by Mr. J. F. Campbell. The author described the various specimens of Lapps met with in a journey through Finland in the past year. The paper was illustrated by numerous original water-colour sketches of persons, habitations, and scenery, as also by a selected collection of articles of dress and objects of silver and bone obtained in that country.—"Notes on the Ethnology of the Indo-Chinese Nations and Tribes," by Col. Phayre, C.B. The history contains the Buddhist account of the first formation of human society, the election of a king, and the grant to him of a share in the production of the soil, the succession of sovereigns, and the spread of their dominion and the Buddhist religion. These legends constitute to this day the foundation of the authority, temporal and spiritual, of the Burmese kings; that authority they continually refer to, as it is ever present to the minds of their subjects. The author, in conclusion, criticized them with the view of eliciting the amount of their real historical evidence.—"On the Characteristics of the South Slavonic Races," by Miss Irby. The authoress described at length the ethnological characteristics of these races, their habits and civilization, from the personal experience obtained in travels through Austria, Greece, and European Turkey in 1862-3-4.

EDINBURGH ROYAL INFIRMARY.

Wednesday, 24th Jan., 1866.

PROFESSOR SPENCE operated to-day upon a man whose case presents some points of interest. Some months ago he came under Mr. Spence's care in the Infirmary, at that time suffering from extensive necrosis of the lower part of the shaft of the femur. About two inches of diseased bone, including the flat portion of the femur which enters into the formation of the popliteal space. The patient progressed most favourably after the operation and everything went on well. Unfortunately, however, the man, so overjoyed at the successful result of his case, ventured too soon upon his legs, with the effect of setting up inflammation in the knee-joint. Latterly the inflammation has terminated in the formation of pus, and when brought into the operating theatre the knee was enormously swollen and fluctuation was distinct. This serious affection of the joint was beginning to tell on the general health of the patient, and Mr. Spence determined to interfere again and give the man the benefit of an operation. The Professor before commencing the operation explained that in the first place he intended to make the incisions in such a way that they might do either for excision of the joint or for amputation. If he found that the condyles of the femur were lying in a necrosed state in the knee-joint, their removal, provided the other bones were not extensively diseased, might be all that was necessary, and the patient's leg would still be preserved. Should, however, the neighbouring structures be the seat of extensive disease then amputation would be necessary. Chloroform having been administered a horse-shoe incision was made across the front of the joint, and the articulation was opened, when it was found that besides the condyles of the femur a large portion of the tibia was likewise involved in disease. As there was therefore no hope of saving the limb amputation at the lower third of the thigh was performed, the anterior flaps being long. A large quantity of thin watery pus escaped when the primary incision was made, and Mr. Spence having first cut away portions of the lining membrane of the abscess painted the rest of it with the tincture of iodine. The Professor remarked that there was less bleeding in this case from the stump than usually took place in disease of this nature. For although the tourniquet was used still the increased vascularity of the textures generally gave rise to considerable hæmorrhage. In this case, owing to the condensed state of the tissues, there was some little difficulty in securing the vessels. The edges of the wound were brought together with silver wire sutures, and some dry lint was applied to the stump. Mr. Spence said that he had thought it his duty to endeavour in the first place to save the man's limb, especially as this was done without in the slightest degree adding to the difficulty or the danger of the subsequent amputation, and he had no doubt the patient would do well.

MEDICAL ANNOTATIONS.

MEDICAL OFFICERS OF HEALTH AND THEIR MASTERS.

THE contemptible figure cut by the Medical Officers of Health in their relations with those whom they are theoretically supposed to warn and to advise, was never more strongly exemplified than in a late discussion held in the St. Pancras Vestry, on the occasion of a report on the

sanitary condition of that parish, by Dr. Hillier. In that report, Dr. Hillier adverts to the threatened approach of cholera to this country, and he very properly advises the local authorities to be on their guard against the insidious enemy; and he tells them that the parish of St. Pancras, which is one of the most populous in the metropolis, ought to be in the van of sanitary science, whereas it is actually in many respects in the rear. The indignation of the parochial bumbles at this report appears to have been almost without bounds, and not only was it pronounced to be "wordy and meaningless," and Dr. Hillier censured for needlessly alarming the public mind, but Dr. Lankester was anathematised as that "wretch of a coroner" who was bringing the vestries into contempt. This treatment of Dr. Hillier ought, under a proper system of sanitary supervision on the part of the Government, to have been simply impossible. The report is a remarkably able and temperate one, and if it had been otherwise, Dr. Hillier might have been made responsible to some superior authority capable of forming an opinion on the matters at issue; but that a learned and conscientious professional gentleman should be visited with vulgar abuse because he has done his duty, is one of the anomalies of our free institutions which we have considerable difficulty in comprehending.

RETROSPECT OF THE JOURNALS.

FROM the *Medical Times and Gazette* we learn that a good deal of excitement has been caused by Dr. Lankester, who held an inquest on the body of a young person who died of fever in the parish of Maulebone. The parochial surgeon had attended twenty-five such cases in one small neighbourhood, and gave it as his opinion that they were in the main due to defective drainage and water supply. For daring to do so the coroner was attacked by the vestry, as he seemed to throw all the blame on them for their want of energy, but by none was he assailed so vehemently as by a member of his own profession, a Dr. Collins.

At the inquest at St. Mary's on the patient who had died while under chloroform an attempt was made by the jury to censure the hospital staff for allowing a junior to administer chloroform. However, it was proved that the gentleman who gave it on this occasion had done so over 400 times; unfortunately, the patient's consent was not asked, and it was, as usual in the majority of such instances, used for what may be called a minor operation—removal of a toe-nail. We have invariably observed that those bear the anæsthetic better who lose some blood, probably by the unloading of the brain vessels.

However, the same coroner, Dr. L., has fallen foul of another medical gentleman, Mr. H. Hume, who was censured by a coroner's jury for refusing to go to a case. "Although he was not present nor asked to attend for the purpose of explanation, a vote of censure was passed. Certainly, to condemn a man unheard is contrary to the principles of English justice. We think there must be some mistake in the newspaper report. It is but just to Dr. Lankester, meanwhile, to direct attention to his tone at an inquest held on a man who had died at St. Mary's Hospital under the effects of chloroform. He distinctly protected the medical men from an imputation of want of care."

In speaking of the honour lately conferred on Sir Dominick Corrigan, the *Medical Times and Gazette* regrets that no such honour has been bestowed on any member of what it calls the "first medical corporation in the kingdom," the Royal College of Physicians.

It is curious, in the present state of the question as to the identity of small-pox and rinderpest, to learn that in 1776 Vacey d'Azur termed the plague *peste variolense*.

At the Metropolitan Association of Medical Officers of Health a very valuable paper by Dr. Montgomery of Madras (son of the late eminent Dublin obstetrician) on the origin and propagation of cholera in India by means of religious festivals and pilgrimages. One of the instances cited is as follows:—

“Situated at a distance of forty-five miles from Madras, and on the western boundary of the collectorate of Chingleput, is a native town called Conjeveram. ‘It is large, pretty, and regularly built; the streets are broad, and planted with cocoa-nut trees, and a small stream runs along its western side. The soil is clayey from decomposition of felspar, which abounds in the granite, and proves very fertile; the river and surrounding tanks are favourable to cultivation. The inhabitants are chiefly ryots’ (cultivators of the soil) ‘and weavers. Many Brahmins reside here, and the large Pagoda or Temple at Conjeveram is greatly famed in heathen mythology. It is one of the strongholds of Hindooism in Southern India.’

“Here, then, we have an example of a sacred shrine, which in some respects is favourably influenced for the existence and maintenance of public health. Many of the inhabitants, more especially those attached to the temples and also the leading cloth merchants of the place, are wealthy. It occupies a somewhat secluded position, and the mode of construction of the town, with a view to the passage of large processions along its leading streets, is favourable to ventilation. The occupations of the people are healthful, much of the weaving (which might seem an unhealthy occupation) is carried on out of doors, and the general health of the people is satisfactory. The festival is comparatively of short duration, and held in the month of May, which is a hot weather month, and not unhealthy, in this part of India. Yet, with all its advantages, the annual feast at Conjeveram is almost as regularly the means of introducing cholera into Madras. Scarcely a year up to 1863 passed without an outburst of cholera during, or immediately subsequent to, the festival, and its appearance in Madras a few days subsequently was directly traced, in many instances, to the visitors returned from Conjeveram.”

In reports of hospital practice we have related some interesting cases of contracted mitral valve, where there were pre-systolic or auricular-systolic murmurs over the left side of the heart. We also find Sir William Ferguson's case of traumatic aneurism involving the aorta and commencement of the arteria innominata. The lesion was produced by the sharp projection of a fractured clavicle.

In the *British Medical Journal* a leading article is devoted to the consideration of Dr. Johnson's new work and theory as to choleraic collapse

In regard to the mortality in Lying-in-Hospitals, Dr. Hervieux of La Maternité, says:—

“1. Moral and physical distress, primiparity, protracted labour, difficult labour, obstetrical manœuvres, merely act as predisposing causes of puerperal epidemics.

“2. Infection and contagion are, *par excellence*, the efficient causes and propagators of these epidemics.

“3. The vitiation of the air by the morbid or physiological secretions of women recently confined, the permanent occupation and the overcrowding of lying-in wards, are the causes which give rise to the infecting principle.

“4. Confinement at their own homes, although only feasible in very few of the cases which come to hospitals, ought to be practised wherever it is possible.

“5. The first measure to be taken in an epidemic is the complete evacuation of the lying-in establishment.

“6. The prophylaxis of these epidemics comprises, amongst others, the following measures. The alternate occupation of wards and beds, a large space given to the beds, the employment of natural and artificial ventilation, the suppression of curtains, the frequent renewal of mattresses, the washing of the walls with chlorine water, &c.

“7. Lying-in hospitals should be of small size.”

Dr. Paterson of Glasgow, has raised an action of

damages against the *Glasgow Morning Journal*, for a letter which appeared in its columns in reference to the Pritchard case.

There seems to be a great dearth of naval medical officers on the West Coast of Africa.

We learn that of all amputations Syme's amputation at the ankle joint was attended by the smallest mortality.

A very interesting case of black cataract, under the care of Mr. H. Walton, is described. It would be an impossibility without the ophthalmoscope to diagnose between such a case and amaurosis.

In the *Australian Medical Journal* Mr. Malcolm relates a case of empyema of the left pleural cavity, in which a novel method of cure was adopted. A communication was discovered between the upper part of the cavity and the pulmonary tubes at the apex of the lung. The patient every night and morning was turned upside down, by allowing his head and body to hang over the bed, when the pus was readily discharged by the mouth.

THE RESOLUTIONS OF THE IRISH MEDICAL ASSOCIATION.

A MOST important series of Resolutions will be found in our Advertising Sheet expressive of the opinion of the Provincial Medical men of Ireland on questions, many of which are of as much interest to our English and Scotch readers as to the gentlemen from whom they emanate. The profession at large have never been fully informed on the topics which have for so many years been under discussion by nearly two thousand of their brethren in Ireland, and we imagine that such matters will not be read with less interest in Great Britain than the *desagremens* of the English Poor-law Medical Service are regarded in Ireland.

VACCINATION AND THE CATTLE PLAGUE.— FAILURE OF VACCINATION.

WE announced in our last number the death of two of the cattle whose supposed immunity from the rinderpest had formed the basis of Mr. TOLLEMACHE'S communication to the *Times*, and we are now enabled to publish in the letters of Mr. BALFOUR the earliest official information as to the failure of the same agency to protect cattle against the disease now raging in Scotland. It remains now to be shown whether vaccination may not afford partial protection, although it fails to secure absolute immunity.

MILITARY SURGERY IN AMERICA.—The Surgeon-General of the United States has published a report, which shows that over 87,000 cases of wounds and 17,000 surgical operations were recorded up to September, 1865. In comparing the numbers of cases of gunshot fractures of the femur, it is found that in the French Crimean army there were 459 such injuries, and in the English army 194, while over 5000 such cases were reported in America. Of excision of the head of the humerus, the Crimean returns give 16 in the British and 38 in the French army, but the American registers contain the detailed histories of 575 such operations.

CHOLERA CONFERENCE.—A Constantinople despatch informs us that the nomination of the members has been completed. Its constitution will be entirely diplomatic. The conference is expected to meet in the first week of February.

Medical News.

ROYAL COLLEGE OF SURGEONS, ENGLAND.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners on the 23rd inst. :—

Bousfield, Edward, Mansfield, Notts.
Chambers, Frederic Evans, Camden-town.
Chiappini, Antonio Lorenzo, Cape of Good Hope.
Earle, Frederick, Edgeware, Middlesex.
Edgelow, George, Kensington-square.
Ennals, Charles Thomas, St. Neots.
Ewen, Algernon, Long Sutton.
Haslam, James, Reading, Berks.
Horne, Edward, Isleworth.
Legg, John Wickham, Alverstoke, Hants.
Lloyd, Ridgway Robert Syers Christian Codner, Bury St. Edmunds.
Major, Napoleon Bisdee, Hungerford.
Manby, Frederic Edward, East Rudham, Norfolk.
Melson, John Waller, Birmingham.
Molynaux, John Lea, Wigan.
Muriel, George John, Ely.
Plaister, William Henry, Bristol.
Shaw, Henry Lissmore, South Mimms.
Wood, Herbert, Ashton-under-Lyne.

The following gentlemen were admitted members on the 24th inst. :—

Ackroyd, George, Leeds.
Bradshaw, Paris.
Eaton, John Chamberlin, Ancaster.
Ellis, William Henry, Willingham, Cambridgeshire.
Farr, Arthur John, Newport, Monmouthshire.
Hewetson, Richard, Baywater.
Hunt, Frederick Everard, Shortlands, Kent.
Jackson, Arthur, Sheffield.
Lawrence, John, Clifton.
Mountain, William John, Leeds.
McWilliams, Joseph McCargher, Omagh.
Nolan, William, Athbay.
Percival, Thomas, Leeds.
Ransford, James Inglis, Sydenham.
Ridley, Herbert, Newcastle.
Royds, William Alexander Slater, Bedford.
Simpson, Thomas Henry, Fore-street.
Smith, Henry Cecil, Baywater.
Taylor, George Christopher, Trowbridge.
Wadd, Frederick John, Kilburn.
Ward, John Bywater, Leeds.
Wright, William Evatt, Brixton.

NEW FELLOWS.—At a meeting of the Council of the Royal College of Surgeons on the 11th inst., the following gentlemen, having been elected Fellow at previous meetings of the council, were admitted as such :—

Allard, William, Tewkesbury; diploma of membership dated April 12th, 1839.
Taylor, Henry Sharp, Guildford; June 12th, 1840.

APOTHECARIES' HALL.—The following gentleman passed his examination in the Science and Practice of Medicine, and received a certificate to practise on the 18th inst. :—

Gowing, Benjamin Chasten, Lowestoft.

TRINITY COLLEGE DUBLIN: MICHAELMAS TERM EXAMINATION FOR M.B.—List issued by the examiners for medical degrees, December, 1865 :—

Swanzy, H. R., B.A. Dub., Dublin Hospitals.
Compton, T.A., B.A. Camb., St. Bartholomew's.
Benson, J.H., B.A. Dub., Dublin Hospitals.
Mayo, C., M.A. Oxon., St. Bartholomew's.
{ Keough, E., M.A. Dub., Dublin Hospitals.
{ Greene, F. W., B.A. Dub., Dublin Hospitals.
{ Gamble, S.B., C.B. Dub., Dublin Hospitals.
{ Higginson, F. W., S.F. Dub., Dublin Hospitals.

Candidates, 10. Unsuccessful, 2.

THE CHOLERA IN PARIS.—There has been no fatal case of cholera in Paris since the 14th inst.

PROFESSOR HUXLEY, F.R.S., will commence his course of lectures at the Royal College of Surgeons on Friday, the 2nd proximo.

PHARMACEUTICAL ETHICS.—Mr. Joseph Ince has been requested by the British Pharmaceutical Conference to write an essay on Pharmaceutical Ethics.

There was a crowded audience on Sunday week at St. Martin's Hall to hear Dr. Carpenter lecture on "The Antiquity of Man." Dr. Carpenter spoke for about an hour and a half, and then there was a performance of sacred music.

A STRONG feeling exists in Paris (says the *Abeille*

Médicale) in favour of making the studies and examination of students more practical than they are at the present time.

THERE were 1569 deaths in London last week, or seventy-two below the computed average. Typhus and whooping-cough appear to be the most fatal causes of mortality.

AMONG the donations by workmen in aid of the Bristol Royal Infirmary acknowledged last week is one of £115 9s. 9d., contributed by the workpeople in the employ of Messrs. Derham, Brothers, whole ale shoe manufacturers of Bristol. Last year the amount thus given was almost as large.

THE cattle disease is spreading in all parts of Holland, notwithstanding the precautions taken by the authorities to prevent the admission of diseased cattle into the country. The regulations issued by the Government on the subject are but little adhered to, and in some places active resistance is made to the officials who attempt to enforce them. At Hagstein the peasants rose against the troops, and were only put down by the arrival of reinforcements.

THE sum of £20,000 has been presented to the Middlesex Hospital, by an anonymous donor.

GLASGOW POLICE BOARD.—The usual fortnightly meeting of the Glasgow Police Board was held on Tuesday—Baird Raeburn presiding. A report by Dr. Gairdner, medical officer, was read, showing that during the past fortnight the occurrence of 193 cases of fever had been reported, as against 228 cases during the previous two weeks. Mr. Ure, in moving the adoption of the report, said that at the same period last year the number of cases reported was 371, as against 193 this year.

THE CATTLE DISEASE—SPURIOUS VACCINE.—A writer in the *Times* says the sudden and great demand for vaccine as a protection for cattle against cattle plague, has led to the manufacture of a spurious material made from collodion and croton oil and tartar emetic. The eruption produced by this stuff is very different from the vaccine.

DR. PETER MACKENZIE, one of the oldest physicians practising in Liverpool, died suddenly on Friday whilst paying a visit to a patient. Dr. Hutchinson of Liverpool, was present at the time. Heart disease was the cause, Dr. Mackenzie having been a sufferer from this for some years.

THREE numbers of Dr. Lankester's *Journal of Social Science* have appeared, and one may judge from their contents of the character which the work is likely to bear. Dr. Lankester evidently, aims at being useful. "Cholera," "Cattle Plague," "Infant Mortality," "Neglected Children," "Crimes and Punishments," "The Office of Coroner," "Martial Law," are some of the subjects analysed at length by competent writers. Those who desire the latest information on these serious topics know where to go to find it.

RINDERPEST AND COW-POX.—An interesting fact is published in the *Wiltshire Journal* of Thursday last, which proves that an attack of rinderpest does not protect cows from cow-pox. It would appear that two dairy cows were seized with rinderpest and were treated by an experienced veterinary surgeon, under whose care they both recovered. But two weeks afterwards they were attacked with cow-pox. Another fact is stated which proves that an attack of cow-pox does not confer immunity from rinderpest. Of five cows which had cow-pox last summer three have just died of the plague.

DR. FORBES WINSLOW.—The Profession and public in general will be glad to learn that this distinguished physiologist, who has been for some time past suffering from severe illness, caused by a fall from his horse, has sufficiently recovered from the effects of the accident to resume his professional duties. We also learn that Dr. Winslow is preparing for publication a raw edition of his work on "Obscure Diseases of the Brain and Mind".

DR. JOHN BROWNE, has been appointed one of the Commissioners on Education for Scotland.

POOR-LAW MEDICAL REFORM.—Mr. Griffin request us to state he has received the following subscriptions towards the funds of the Association :—J. Davison, Boston, 5s.; I.

Johnson, Newark, 5s.; G. McMaster, Portsea 1s and 5s.; P. Frank, M.D., late 80th Regiment, Mentone £3; G. Bury, Whetstone, 1 s.; B. Hands, Edmon-ton, 10s.; A. T. Brett, Watford, 10s.; H. Terry, junr. Hardingstone, 5s.; E. Dudley, Hardingstone, 5s.; W. Percival, Northampton, 5s.; J. M. Bryan, Northampton, 5s. T. H. Willis, Tavistock, 5s. Mr. Prowse of Amersham, has received the following: R. Brent, St. Thomas, £1; H. Kelly, Uxbridge, 10s.; P. Dickenson, Chelsea, 21s.; R. Kerswill, St. Germans, 5s.; E. M. Wrench, Bakewell, 5s.; H. Brooks, Bridge-water, 10s.; J. Burton, Walsall, £1; N. Buckley, Rochdale, £1; W. Wilson, Chesterfield, £2 2s.; Wright and Allen, Bashford, 5s.; J. Hembrough, Cai-stor, 10s.; E. Buckel, Winchester, 10s.; W. H. Griffith, Henckley, 10s. 6d.; G. G., 10s.; Dr. Bell, Cocker-mouth, 10s.; R. Bryden, Tiverton, 5s.; C. E. Claremont, St. Pancras, 10s.

NOTICES TO CORRESPONDENTS.

Mr. Griffin's letter is inserted.

Dr. Lethby's Report on the Cattle Plague has been received.

Dr. B.—The law of the case stands thus:—A Fellow of a College of Physicians cannot recover his fees in an action at law if the College to which he belongs has passed a bye-law to that effect. All other members of the profession may sue for reasonable charges. The jury, however, will decide upon the reasonableness or otherwise of the demand made.

Expers.—We are not aware of the existence of any Inebriate Asylums in England.

THE GRIFFIN TESTIMONIAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The following subscriptions have been further received on behalf of the above fund:—

Heynes Hardwicke, Esq., Hempnall	£0 5 0
Amount previously announced	132 14 3
Received at "Lancet" office	9 9 0

Yours obediently,

ROBERT FOWLER, M.D., Treasurer and Hon. Sec.

145, Bishopsgate-street, Jap. 24, 1865.

MEDICAL DIARY OF THE WEEK.

THURSDAY, FEB. 1.

ROYAL INSTITUTION.—3 p.m. Professor Tyndall, "On Heat."
CHEMICAL SOCIETY.—3 p.m. Dr. Gilbert, "On the Utilization of Town Sewage."

HARVEIAN SOCIETY OF LONDON.—8½ p.m. Mr. Victor de Mérie, "On Syphilization."

FRIDAY, FEB. 2.

WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ p.m.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Prof. Huxley, "On the Classification and Structure of the Mammaria."

ARCHAEOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—4 p.m.
ROYAL INSTITUTION.—8 p.m. Earl Stanhope, "On the Influence of Arabic Philosophy in Medieval Europe."

WESTERN MEDICAL AND SURGICAL SOCIETY.—8 p.m. Mr. C. Hunter, "A Case of Stricture of the Oesophagus; with Remarks."

SATURDAY, FEB. 3.

ST. THOMAS'S HOSPITAL.—Operations, 9½ p.m.
ST. BATHOLOMEW'S HOSPITAL.—Operations, 1½ p.m.
KING'S COLLEGE HOSPITAL.—Operations, 1½ p.m.

ROYAL FREE HOSPITAL.—Operations, 1½ p.m.
CHAIRMAN-CROSS HOSPITAL.—Operations, 2 p.m.
ROYAL INSTITUTION.—3 p.m. Prof. Westmacott, "On Art Education, and how to Observe in Fine Arts."

MEDICAL APPOINTMENTS.

ENGLAND.

W. F. Butt, M.R.C.S.E., has been elected Resident Surgeon to St. Pancras Workhouse and Infirmary, vice J. Roberts, L.R.C.P.L., deceased.

E. F. Fussell, M.B., M.R.C.P.L., has been appointed Physician to the Brighton Dispensary.

H. C. Hilliard, L.R.C.P.L., has been elected House-Surgeon to the Surrey County Hospital at Guildford.

R. W. Soper, M.R.C.S.E., has been elected Resident House-Surgeon to the South Devon and East Cornwall Hospital, Plymouth, vice Geo. Miles, M.R.C.S.E., resigned.

T. J. Webster, M.R.C.S.E., has been appointed Assistant Medical Officer to the Bridge-street Workhouse, Manchester, vice A. Philipps, M.R.C.S.E., resigned.

Alfred G. Canton, M.R.C.S.Eng., has been appointed Assistant Dental Surgeon to the Dental Hospital of London, Soho-square.

William Hoffmeister, M.D., has been elected one of the Surgeons to the Cowes Dispensary.

W. L. Hopkinson, M.D., has been appointed Consulting Physician to the Stamford and Rutland Infirmary.

William Newman, M.D. Lond., has been appointed Surgeon to the Stamford and Rutland Infirmary.

C. F. Oxley, L.R.C.P. Edin., has been appointed Resident House Physician to the Westminster Hospital.

T. H. Redwood, L.R.C.P. Lond., has been appointed Senior Assistant-Surgeon to the Rhymer Iron Works, Monmouthshire.

Frederick T. Roberts, M.B. Lond., has been appointed Lecturer on Comparative Anatomy and Zoology at the Liverpool Royal Infirmary School of Medicine.

O. Bohun Shore, M.D. Edin., has been appointed Physician to the Stamford and Rutland Infirmary.

IRELAND.

R. Boxwell, L.K.Q.C.P.I., has been elected Medical Officer to the Workhouse Infirmary and Fever Hospital of the Gorey Union, county Wexford, vice J. Symes, L.K.Q.C.P.I., resigned.

H. Wilson, F.R.C.S.I., has been admitted a Member of the Royal Irish Academy.

Joseph Clarke, L.K.Q.C.P.I., has been appointed Surgeon to the Constabulary, Ballieborough, county Cavan.

Dr. John Foster Rowan, has been elected Medical Officer of the Cragknock Dispensary District, Kilmash Union.

Dr. Patrick W. Dillon, has been elected Medical Officer of the Carrigaholt Dispensary District, Kilmash Union.

SCOTLAND.

Alexander D. Anderson, M.D. Edin., has been nominated a Director of the Glasgow Royal Lunatic Asylum.

William Lyon, M.D. Glasg., has been nominated a Director of the Glasgow Royal Lunatic Asylum.

John Pagan, M.D. Edin., has been re-elected a Director of the Glasgow Royal Lunatic Asylum.

POOR-LAW VACANCIES.

Chesterfield Union.—Bolsoever District; area 10,366; population 2402; salary £20 per annum.

Dewsbury Union.—Mirfield District; area 3548; population 9263; salary £30 per annum.

Haslingden Union.—Edenfield District; area 5259; population 4723; salary £12 10s. per annum.

Leominster Union.—First District; area 36,641; population 10,740 and the Workhouse; salary £200 per annum.

Neath Union.—First Central District; population 12,935; salary £65 per annum. Also the Workhouse; salary £30 per annum.

Stoke-upon-Trent Parish.—Longton District; area 1363; population 16,742; salary £35 per annum.

Watford Union.—Rickmansworth District; salary £35 per annum.

Witney Union.—Eynsham District; area 16,618; population 5237; salary £113 per annum.

BIRTHS.

On the 5th inst., at Sibford-Ferris, Banbury, Oxfordshire, the wife of C. F. Knight, M.R.C.S.E., of a daughter.

On the 18th inst., at Stanley-terrace, Kensington-park-gardens, the wife of J. Waggett, M.D., of a son.

On the 24th inst., at Everton-road, Liverpool, the wife of Dr. A. F. Graham, of a daughter.

On January 18, at Eastwood, Notts, the wife of Edward A. Browne, M.D., of a daughter.

On January 14, at 104, Lansdowne-road, Kensington-park, W., the wife of Dr. A. Campbell, late of Darjeeling, of a daughter.

On January 22, at 83, Gower-street, the wife of Dr. A. Duncan, of a son.

On January 19, at Bracknell Lodge, Hartley-row, Hants, the wife of Thomas A. Freeman, M.R.C.S.Eng., of a son.

On January 23, at Mitcham, Surrey, the wife of Edward Marshall, M.R.C.S.Eng., of a daughter.

On January 13, at Stockwell, the wife of William Soper, M.R.C.S.Eng., of a daughter.

On the 18th inst., at Castle-terrace, Edinburgh, the wife of J. Bell, M.D., of a daughter.

On January 5, Mansion House-road, Grange, Edinburgh, the wife of N. Bethune, M.D., of a daughter.

On January 10, at Charlotte-square, Edinburgh, the wife of J. B. Tuke, M.D., of a son.

On January 11, at Calder-bank, Midcalder, the wife of W. Watson, M.D., of a son.

On the 25th inst., at Hawkins-street, Londonderry, the wife of Edward Smith, M.B., Assistant-Surgeon Londonderry Light Infantry, of a daughter.

On January 21st, at Castleblayney, the wife of Isaac Ashe, Esq., M.B. T.C.D., of a son.

MARRIAGES.

On January 22, at Christchurch, Clapham, James V. Bell, M.D., F.R.C.S., to Susannah Charlotte, youngest daughter of the late E. M. Sparkes, Esq.

On January 28, at St. George's, Bloomsbury, W. Spence Watson, F.R.C.S.Eng., to Georgiana Mary Jane, eldest daughter of G. J. J. Mair, Esq.

December 23, 1865, at the Cathedral, Calcutta, Whitley Stokes, Esq., Secretary to the Legislative Council, eldest son of Wm. Stokes, M.D., 5, Merrion-square, to Eliza Mary, only daughter of the late Colonel F. R. Bazeley, Bengal Artillery.

NEW WORKS PUBLISHED FROM THE 1ST TO THE 16TH OF JANUARY.

(From the *Publisher's Circular*.)

Blake (John A., M.P.)—The Moral Treatment of Insanity. Post Svo. sewed, 1s. (Churchill.)

Brodie (Sir Benjamin C.)—Autobiography. 2nd edit. 12mo. pp. 188, cloth, 4s. 6d. (Longman.)

Cockle (John M.D.)—On Intra-Thoracic Cancer. Part 2, Contributions to the Pathology of the Disease. Svo. sewed, 5s. (Churchill.)

Edwards (E., B.A.)—Photographs of Eminent Medical Men. Part 6, 3s. (Churchill.)

Half-Yearly Abstract of the Medical Sciences, July to December, 1865. Post Svo. pp. 370, cloth, 6s. 6d. (Churchill.)

Hugman (William Curtis)—On Hip-joint Disease. 2nd edit. Svo. pp. 80, cloth, 3s. 6d. (Churchill.)

Owen (Richard)—On the Anatomy of Vertebrates. Vol. 1, Fishes and Reptiles. Svo. pp. 633, cloth, 21s. (Longmans.)

Treasury of Botany: a Popular Dictionary of the Vegetable Kingdom; with which is incorporated a Glossary of Botanical Terms. Edited by J. Lindley and Thomas Moore. Illustrated by numerous Woodcuts. Two Parts, 12mo. pp. 1254, cloth, 20s. (Longmans.)

ERRATUM.—In our Hospital Report of cases in the London Surgical Home, Dr. Barratt is said to have stated that the tumour in Case 3 was composed of "five hundred cysts;" it should have been "five or six cysts."

LECTURES

ON THE NATURE, CAUSES, AND TREATMENT OF DYSPEPSIA.

DELIVERED AT THE QUEEN'S HOSPITAL, BIRMINGHAM.

By BALTHAZAR W. FOSTER, M.D., F.L.S.,

MEMBER OF THE ROYAL COLLEGE OF PHYSICIANS, LONDON; LICENTIATE OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND; PHYSICIAN TO THE QUEEN'S HOSPITAL AND PROFESSOR OF CLINICAL MEDICINE IN QUEEN'S COLLEGE, AND OF THERAPEUTICS AND MATERIA MEDICA IN SYDENHAM COLLEGE, BIRMINGHAM.

LECTURE III.

GENTLEMEN,—In errors of diet we have before us a number of conditions which are generally and truly recognised as the frequent causes of disordered digestion. In order that we should appreciate these errors and understand their part in the production of disease, we must first have some knowledge of the physiological value and action of the various substances which we include under the term "Food." You have doubtless heard much on this subject in the course of lectures on physiology. I need therefore only recall to your minds certain main facts which are necessary to be kept in view. The food of man consists of materials of two kinds, the organic and the inorganic. The organic materials only are commonly looked upon as nutrients, yet each is essential. An animal deprived of the seemingly insignificant inorganic matters which enter into all food soon shows signs of the unnatural deficiency. We need not, however, in classifying foods, make a distinct class of these inorganic or mineral constituents. Modern research has shown that they (and water) are essential ingredients of all dietaries, but as they are present in the necessary proportions in the organic foods, we shall proceed to the classification of the latter without further observation. We may divide food, then, into the following classes: the Saccharine, the Proteinous, and the Oleaginous. The first class includes the various vegetable substances (consisting of C. H. and O. alone) analogous in composition to Sugar, and capable of being converted into it—*e. g.*, starch, gum, cellulose, &c. The second contains all those substances allied to albumen, be they vegetable or animal in their origin, and composed of C. H. N. and O.—*e. g.*, Fibrin, Albumen, Casein, Gelatine, &c.

The third group, derived from both the animal and vegetable kingdoms, is characterised by the great excess of C. and H. in their composition and the absence of N.—*e. g.*, Oils, Fat, Butter, &c.

Any one of the groups cannot, taken alone, support life, but on a proper proportion of the three classes must nutrition depend. These forms of food will, as to quantity, vary in accordance with the special needs of the system.

In the active, in whom there is a large amount of muscular exertion, the proteinous class must be supplied in a larger proportion. This is best afforded by an increase of animal food, for while the vegetable kingdom can supply this form of aliment, yet the tendency of an exclusively vegetable diet is to lower the proportion of the red corpuscles of the blood; that of an animal diet to increase

them. The Oleaginous are required in larger proportion under the influence of a low external temperature, while in the opposite conditions the Saccharine are advantageously substituted. A relative excess in the use of any of these forms of food above the requirements of the system is not only productive of gastric difficulty, but is also powerful in the development of certain diatheses—*e. g.*, the rheumatic due to excess in starchy food, the strumous to deficiency of oleaginous matter, &c. We cannot, however, lay down laws as to the quantity of food required for the maintenance of the body in health, for this varies much with age, sex, habits, and constitution. It is especially important for us, viewing this matter from the pathological point of view, to bear in mind this fact; and while physiologists may form average estimates of the necessities of the economy, we must be guided by individual peculiarities; we must also recollect that the digestibility of the various forms of food is a matter of great importance, and that on this as a quality depends for us the nutritive value of many a substance. A good dietary should possess these two great qualifications:—1. It should be adequate to the perfect nutrition of the body; and 2. It should consist of material easy of digestion. Bearing this in mind, we shall consider diet with reference to

- (a) The influence of food.
- (b) The influence of drinks.
- (c) The frequency of meals.

(A) The quantity of the food taken may err either by excess or by defect; when taken in excess of the real wants of the system symptoms are not long wanting to point out the error. A sense of satiety and fullness soon tells us that we have exceeded the limits of a just repast, and have taken more than the system demands. The appetite should not be followed as the sole guide, as the digestive power should be consulted, and in the agreement of these two the physiological law may be found. Eating beyond that period which is marked by a sense of ease and satisfaction is eating to excess, while the effects of a constant custom of feeding to repletion are too frequently met with by the physician, even in the nineteenth century. The habit of eating too quickly is often the real cause of this, as I shall have occasion to point out hereafter when speaking of mastication. A single error in this direction is usually followed by a slight attack of what we have termed accidental dyspepsia, but the habit of eating more than is necessary is followed by the graver ills of chronic dyspepsia. You have occasionally seen in the hospital wards examples of the effects of deficiency in the quantity of food, and you have remarked in such cases an irritability and want of power in the digestive organs, which, with other symptoms, have told us that we had to deal with veritable cases of starvation. In the out-patient room we often see cases where the deficiency of the more nutritious forms of food, and the long use of a diet in itself not fully competent to supply the necessary materials for the support of the body, have brought about various functional derangements of the stomach.

Dyspepsias, however, arising from a deficiency of food are much less common than those which depend upon excess. Food by its quality may be a cause of disordered digestion, as, for example, when the climatic conditions and the changes in diet thereby necessitated, to which I have before alluded, are disregarded. But more commonly we find that the quality of the aliment produces dyspepsia by virtue either of its indigestibility or its want of nutritive value. The digestibility of the various edible substances used by us differs, as you know very much, and Dr. Beaumont has drawn us up a well-known table where we can see many kinds of food arranged in their order of merit. This table I have often alluded to, and you will find it useful to consult. Dr. Beaumont's almost unrivalled opportunities of investigating this point has, thanks to his industry and the docility of his patient, much increased our knowledge of the physiology and pathology of the stomach. Food may be indigestible either by its nature or by its bad preparation. The poor are exposed to both

these forms; their food, often in itself difficult to digest, has none of these aperitifs toned down by a careful preparation (which is, as has been well said, the commencement of digestion), and thus passes through the alimentary tract, affording not only little nourishment, but also causing no small irritation. The nutritive value of food is often very defective, and soon becomes a source of gastric trouble. The use of a diet consisting almost exclusively of starchy and fatty matters by certain classes of our poor, whereby the system is insufficiently nourished and the digestive organs disturbed by the want of that variety of material which is necessary for their normal working, is a case in point. This we might almost call with Dr. Brinton, "starchy dyspepsia," and we might point to another form prevalent among the upper classes, which might equally well be termed the "proteinous." For as I have already shown it is only by that diet which insures the admixture of the various constituents of our food in their proper proportions, that we can hope to escape digestive difficulty. In early life, the bad preparation and the indigestibility of food is certainly one of the commonest causes of disease.

Before leaving the subject of food, let me add this, that meat should be in a wholesome and undecomposing state. It has been suggested* that many of the cases which crowd our hospitals during the warmer months, owe their maladies to this cause, and the prevalence of disorders of the digestive organs among people who indulge habitually on decaying flesh has been well described by Dr. Panum.†

(B.) The action of liquids in reference to the digestive process we may consider to be two-fold; in the first place, taken with moderation they materially assist the work of the stomach by softening and dissolving many of the ingesta; and in the second place, they add to the nutrition of the system by the nutritive materials they contain.

As I have previously mentioned, water is an essential constituent of the animal economy (forming indeed nearly 4-5ths of its weight), and therefore eminently necessary to nutrition, but we must also recollect that through its solvent properties many mineral substances are introduced into the system. The quantity of fluids necessary to be taken each day cannot be strictly defined, as it varies with many conditions—*e. g.*, temperature, exertion, &c.; but we have authority for supposing that at least 6lbs. are required daily. The beverages taken at meals chiefly interest us on this occasion, and we can easily understand that these may be found injurious, either by their quantity or their quality. In moderate quantities they excite the secretion of the saliva and gastric juice, and assist in promoting the changes of the food. Taken in excess, they dilute the digestive fluids, and thus impede the transformation of the food. On the other hand, those who drink too little at meals deprive their digestive organs of a natural assistance, and thus retard their functions. In referring to the qualities of the drinks taken during meals we enter on a subject full of interest, but which must not delay us long.

The liquids taken in this country at meals consist of water, wine, beer, spirits, tea, coffee, &c. Of these water is the natural beverage, and when pure can impede the digestive process only when taken in excess, or when taken too cold. Not content often with taking a quantity of cold drink with our meals, we often commit the additional error of eating, after a full repast, ices. More or less retardation of the digestive process inevitably follows, for one of the essential conditions for digestion is the maintenance of an uniform temperature in the stomach of about 100° F. Dr. Beaumont tells us an experiment in point. Into the stomach of Alexis St. Martin during digestion he injected a single gill of water at 50°, this lowered the temperature 30°, and half an hour elapsed before the normal tempe-

ture was regained. The natives of some other lands are wiser in this respect than we ourselves, and carefully eschew at their repasts the use of liquids that have not received a slight addition to their temperature. And we ourselves endeavour as a rule to neutralize the ill effects of the cold potatoes taken at dinner by the warmth of a cup of tea or coffee taken soon after. Fluids containing alcohol are injurious in proportion to the amount of alcohol. As I have already told you the direct action of alcohol on food undergoing digestion is to retard its transformation, and it does so in proportion to its concentration. The lighter wines taken at meals have very little injurious action on the assimilative process, the heavier wines and ardent spirits interfere more with the digestive act. But we must not let another consideration escape us, that these agents in many cases favour digestion (even as condiments) by stimulating the secretion of gastric juice. This effect they may produce either by their direct action on the stomach, or by their secondary action through the nervous centres. In certain cases they are useful in this way, but this treatment of imperfect digestion is one very apt to have ill results in the hands of our patients. For the abuse of liquids taken to this end and of condiments is fraught with most serious consequences. These beverages have also another claim to our attention on account of the nutritive matters they hold in solution. The various kinds of beer and porter contain most nutriment, and we consider them more justly entitled to be termed foods than either wine or ardent spirits. Some, however, contain a large quantity of alcohol in addition and thus become injurious to digestion. The lighter varieties or bitter ales containing some 5 per cent. of alcohol are best suited to the digestive organs. Cider and acid drinks favour the production of dyspepsia, and the same may be said of aerated waters taken habitually. Tea and coffee may be ranked together as the supplanters of the milk which once formed the general drink of our population. As nutrients they are much inferior in value, but they possess other properties which have rendered them more popular. On digestion, tea, and to a less extent coffee, exercise a favourable influence, and at the same time they quicken the vital processes. Coffee from the quantity of milk taken with it, is less suited as a beverage after the principal meal, its action when strong has also occasionally unpleasant effects on the intestinal canal. The tea taken by the poorer classes is a fruitful source of dyspepsia, as it is taken before or in the absence of food rather than after it, and also on account of the tannin which is extracted from it by faulty preparation. Tea is essentially a beverage suited to a *well-fed* people.

(C.) The arrangement of meals is often found to be a cause of digestive maladies. Due regard is not paid to this subject, and frequently you will find attention to this point will enable you to relieve obstinate cases. The frequency with which food is required varies with age. In infancy the rapidly growing tissues demand a very constant supply of nutriment, in childhood the demand is less; it becomes least frequent in old age. In the upper classes the meals are too much crowded into the later hours of the day, and in consequence long fasts are too often incurred between breakfast and dinner, whereby in some cases the digestive power is weakened and the appetite destroyed, and in others the sensation of hunger prompts to excess, and the hours for repose arrive long before the stomach has completed its labours. This is not favourable to healthy action, and the habit of taking a substantial luncheon between breakfast and dinner is often injurious. For by this means, on the arrival of the second meal, the first has often not been completely digested, and though an appetite is wanting food is taken partly by habit and partly from a conviction that it is necessary, and a troubled digestion follows. The hours of meals should be regulated with care, so that no one digestive act should interfere with the succeeding, and so that the stomach should have an intervening period of rest. The observance of this rule would prevent a crowd of dyspepsias.

ON AMPUTATION BY FLAPS IN THE LEG.

By W. B. MCKINLAY, M.D., F.R.S.E., &c.,

SURGEON, INFIRMARY, PAISLEY.

EVEN at the risk of being accused of having an infatuation, I cannot by any means agree to Mr. Glascott R. Symes' condemnation of the flap amputation in the leg, and more especially when he blames that method as being more liable to secondary hæmorrhage than the circular. I am and have been in the habit of constantly amputating by the flap method, and never considered it more liable than the circular to hæmorrhage; however, I should mention that I constantly use acupressure, and the first time I used that method was in a case where I had very great difficulty in using the ligature, indeed the artery could not be laid hold of, I even sawed a small portion off the tibia and fibula a second time, but even then it could not be caught until I procured a common darning needle, with which I pressed the artery against the bone. But to consider the *pros* and *cons.* with regard to the flap.

1st. With the flap there is generally less hæmorrhage, the amputation taking up less time.

2nd. There is a much better cushion formed at the end of the stump.

With regard to the first of these, I may state, in passing, that I never use a tourniquet, but depend solely upon an assistant for the restraining of the hæmorrhage by compression with his fingers, and a most excellent one I have in my friend Dr. Richmond. It is very much more easily accomplished, indeed it never requires the knife to be raised from the limb until the cutting is finished, or rather it only requires after a very small cut between the bones. With regard to the slicing of the arteries any risk from that is easily overcome by the needles. Indeed amputation by the flap when acupressure is used may be completely finished with only one assistant, that is he who compresses the artery, as I accomplished in a case I had.

With regard to the second, it assuredly forms a much better cushion, and in these days of conservative surgery, when we amputate as far from the centre of the body as is consistent with the safety of the patient, we are oftener likely to get a sufficient amount of tissue for a flap where we would not get a good circular—at least I have generally found it so. I always make it a point of operating even at the very edge of sound tissue.

With regard to the objections, I do question very much whether there is more raw surface exposed in a flap than in a circular. There is a certain amount of surface to be covered; now does it matter whether that is done by one piece or by an edging all around. A well-adjusted flap calculated for the end of the limb amputated will, I am sure, measure as little superficially as the circular edge of the circular amputation, so to speak.

Another objection is the redundancy of the muscle; this in very muscular subjects can easily be avoided by using Skey's method, that is, taking the posterior flap from only a portion of the calf, and dividing the rest transversely. In ordinary subjects I have not found very much inconvenience from it; in one old woman, aged sixty-five, I had union by first intention, at least the whole of the flap adhered, and there was only a line of purulent matter round the edges for a short time, and even although muscular tissue becomes absorbed, it leaves a firm tissue which assists as a most excellent covering of the bones.

With regard to the slicing of the vessels and the difficulty of applying a ligature when the artery is cut obliquely across, I can only recommend the use of acupressure. In not one single instance have I ever had secondary hæmorrhage when I used the acupressure needles, and I have now done so for at least two years almost in every case of amputation and operation requiring the arrestment of arterial hæmorrhage, for the last year I should say at least in thirty different instances, notwithstanding what Mr. Symes states—viz., that secondary hæmorrhage is very likely to occur when acupressure is had resort to with the

ligature. I have had repeatedly secondary hæmorrhage, but never with the needle. Another great matter in their favour is the facility with which they can be applied, one hand being able to do it, whereas with the ligature two pairs of hands are required. Again, I remove the needles in from forty-eight to sixty hours in amputations of the leg, and I have not seen even a drop of blood following their removal. I hope that Mr. Symes and other hospital surgeons will not altogether cease from performing amputation by flap, but as ligatures have failed try it in conjunction with acupressure, when I am sure they will be equally as fortunate as I have hitherto been.

TEMPERATURE OF THE BODY IN FEVER.

No. II.

By THOMAS WRIGLEY GRIMSHAW, A.B., M.B.Dub.,

PHYSICIAN TO CORK-STREET FEVER HOSPITAL, LECTURER ON MATERIA MEDICA IN STEEVENS' HOSPITAL.

(Continued from page 74.)

Case 12.—Ellen B., admitted December 23, 1865; eight days ill before admission; delirious; maculated.

		Pulse.	Temperature Fahr.
1865—December	23	140	103·50
"	24	120	103·50
"	25	120	102·50
"	26	144	103·00
"	27	132	102·00
"	28	120	102·50
"	29	120	101·00
"	20	126	99·00
"	31	104	99·00
1866—January	1	120	98·50

"	9	90	98·75
"	10	96	98·50
"	11	96	98·50
"	12	84	98·75
"	13	96	98·50
"	14	75	99·50

Convalescent.

This case is remarkable on account of the long continuance of a temperature above natural, although the patient appeared quite well. On the day on which she was sufficiently well to be considered convalescent, the temperature was still above 98 deg.

Case 13.—Mary McG., age 19 years; admitted January 1st, 1866; five days ill before admission, nursing a child five months old; maculated.

		Pulse.	Temperature Fahr.
January	1	136	104·00
"	2	144	104·00
"	3	144	102·50
"	4	144	103·00
"	5	144	103·75
"	6	130	104·00
"	7	120	102·00
"	8	120	102·75
"	9	108	99·00
"	10	96	99·00
"	11	96	100·00
"	12	120	99·25
"	13	108	99·50
"	14	108	99·00
"	15	96	98·25
"	16	84	99·75
"	17	110	99·00
"	18	96	99·00
"	19	120	99·00
"	20	96	98·25

Convalescent.

This was an ordinary case of severe typhus, without complication. It may be remarked that the rise of temperature on January 11th was followed by a severe pain in the left ear, on the 12th.

Case 14.—Daniel B., age 47, admitted January 4, 1866; eight days ill before admission; tongue brown in centre, with white band on either side, and red at the edges.

	Pulse.	Respiration.	Temperature Fahr.
January 5	96	30	102.25
" 6	Not taken.	Not taken.	Not taken.
" 7	84	20	97.50
" 8	80	22	98.75
" 9	108	20	101.00
" 10	70	20	100.50
" 11	96	20	99.00
" 12	72	18	98.25
" 13	84	20	98.50
" 14	98	20	98.00

Convalescent.

This case it was thought would prove one of typhus, but did not, the patient being discharged quite well on January 15th.

Case 15.—James C., age 40, admitted January 8th; eight days ill before admission; mottled.

	Pulse.	Respiration.	Temperature Fahr.
January 9	120	28	101.00
" 10	120	24	104.25
" 11	120	24	104.75
" 12	132	26	104.75
" 13	120	36	101.50
" 14	150	50	102.00

Died at two p.m. on 14th.

This patient was a heavily-built man, a very bad subject for typhus. He was maculated with large dark, but not numerous, spots.

Case 16.—Alexander McK., age 44 years, admitted January 11th, 1866; five days ill before admission; maculated.

	Pulse.	Respiration.	Temperature Fahr.
January 11	120	24	101.50
" 12	144	30	101.50
" 13	120	24	100.50
" 14	150	24	101.00
" 15	144	40	100.25
" 16	135	36	101.00
" 17			Died.

This case is remarkable as having a comparatively low range of temperature; the patient's brain was scarcely affected, never being delirious, and scarcely even stupid; so little so, that the day before his death he offered to hold the thermometer himself while I went to the other end of the ward.

Case 17.—Michael B., age 14 years, admitted January 13th, 1866; maculated.

	Pulse.	Respiration.	Temperature Fahr.
1866—Jan. 13	135	24	103.25
" 14	144	36	103.50
" 15	120	24	102.00
" 16	120	36	101.75
" 17	108	24	100.75
" 18	81	24	98.50
" 19	84	20	98.00
" 20	90	16	97.00
" 21	80	20	97.00

Convalescent.

This was quite a typical case of typhus, without complication.

Case 18.—Julia M., age 12 years, admitted January 13th, 1866; ill seven days before admission.

	Pulse.	Respiration.	Temperature Fahr.
January 13	144	25	103.50
" 14	130	24	102.00
" 15	120	24	102.75
" 16	150	24	103.25
" 17	120	26	102.25
" 18	125	60	104.25
" 19	120	32	104.50
" 20	120	40	102.50
" 21	108	40	102.75
" 22	120	30	103.50
" 23	108	24	101.60
" 24	84	24	99.80
" 25	100(?)	22	99.00
" 26	80	24	99.00

Convalescent.

This was quite a typical case of typhus without spots, as is of frequent occurrence at such an age.

Case 19.—Catherine C., age 36 years, admitted January 15th, 1866; densely maculated.

	Pulse.	Respiration.	Temperature Fahr.
January 15	98	19	100.50
" 16	110	20	103.50
" 17	100	18	102.50
" 18	120	20	104.00
" 19	108	20	102.50
" 20	96	24	102.25
" 21	100	20	97.00
" 22	95	22	97.75
" 23	90	24	97.75
" 24	84	20	98.00
" 25	75	18	98.00

Convalescent.

An ordinary case of typhus. In this case there was a sudden fall of temperature on January 21st, after which the patient rapidly recovered.

Case 20.—Mary H., age 19, admitted January 16th, 1866; eleven days ill before admission; densely maculated.

	Pulse.	Respiration.	Temperature Fahr.
January 16	120	60	104.50
" 17	120	24	103.00
" 18	132	50	103.75
" 19	120	45	101.50
" 20	96	32	100.40
" 21	95	24	99.25
" 22	96	25	97.80
" 23	96	24	98.00
" 24	84	28	99.00
" 25	84	20	98.80
" 26	75	18	98.00

Convalescent.

The only complication in this case, which was one of pure typhus, was slight bronchitis.

Case 21.—Mary K., age 14 years, admitted January 16, 1866; maculated.

	Pulse.	Respiration.	Temperature Fahr.
January 16	130	60	104.00
" 17	132	34	102.25
" 18	120	42	102.25
" 19	150	44	103.75
" 20	144	45	103.75
" 21	120	36	102.50
" 22	90	36	98.25
" 23	96	30	98.50
" 24	84	22	98.25
" 25	80	24	98.25
" 26	72	20	98.00

A usual typhus case.

Convalescent.

Case 22.—James S., age 26 years, admitted January 19th, 1866; maculated; bronchitis.

	Pulse.	Respiration.	Temperature Fahr.
January 19	120	28	103.00
" 20	104	21	102.50
" 21	120	24	101.75
" 22	130	28	101.50
" 23	120	24	100.50
" 24	108	24	100.75
" 25	98	25	100.75
" 26	110	28	99.00
" 27	100	24	98.50
" 28	150	40	96.50

Died.

It is to be remarked that in this case the patient had recovered his usual temperature, when a fall, accompanied by a great rise in the rate of the pulse and respiration, preceded death.

Case 23.—Ann C., age 25, admitted January 22, 1866; eight days ill before admission; densely maculated.

	Pulse.	Respiration.	Temperature Fahr.
January 22	140	38	104.00
" 23	144	36	104.00
" 24	130	46	103.50
" 25	150	60	104.00

Died.

This case had severe chest complication, which was the chief cause of her death.

(To be continued.)

Proceedings of Societies.

HARVEIAN SOCIETY OF LONDON.

JANUARY 18, 1866.

Dr. TYLER SMITH, President.

MR. BALMANNO SQUIRE exhibited

SPECIMENS OF THE SKIN-ERUPTION OF THE CATTLE
PLAGUE.

The specimens were taken from a cow dead of the cattle plague on the seventh day of the disease. The one, which was the udder of the cow, exhibited near the roots of the teats several well-marked crusts about the size and thickness of a split pea, distinct from one another, of a brown colour, of a cheesy consistence, and of a greasy character; in fact, exhibiting all the characters of the berry-like crusts produced by small-pox on the human subject.

Portions of the erythematous skin in the neighbourhood of them were the seat of a flaky desquamation.

The other specimen was a portion of the skin off the belly of the same cow. This skin, which was slightly reddened, was the seat of a diffused mealy desquamation, and exhibited several more deeply reddened patches of the area of a split pea, on which the desquamation was much scantier than elsewhere.

The red spots were scattered over the surface at intervals of from half an inch to two inches.

Mr. Squire stated that in several plague-stricken cattle that he had examined, the eruption presented similar characters, and that no human skin disease that he had yet seen resembled the skin eruption of the cattle plague on the udder so closely as the eruption of small-pox. He pointed out the great similarity in consistence and suppleness of the human skin to the skin of the cow's udder, and remarked that it was in this situation that it would be most fair to compare the bovine with the human eruption.

A paper was read by Dr. CHARLES DRYSDALE

ON THE MEDICAL ASPECTS OF PROSTITUTION.

I have had my attention, said the author, lately directed towards the subject of prostitution by conversation with Professor Boeck of Christiania. It is, I think, an important subject, and one scarcely frequently enough discussed among medical men, perhaps the only class as yet able to speak intelligibly on the matter, familiar as they are with the details.

I define a prostitute to be a woman, who habitually, and with scarcely any distinction of persons, save for their power of paying her, gives for hire her bodily functions, which other women only give for affection or desire. It is most important, in my opinion, to keep to this definition in discussing the question, and not, as Wardlaw and others have done, to call the first connexion of an unmarried woman prostitution. Such definitions only confuse and render discussion impossible. There are said by authorities to be about 4000 of *such* prostitutes generally in Paris, and about 12,000 in London.

The causes of this phenomenon are partly *physiological*, and partly *social*. Thus, the appetite for sex is, of course, the prime mover of prostitution. This appetite is, like gravitation, a constant force, tending to produce certain results, unless counteracted. The sex-appetite, however, is not alone sufficient to account for the fact of prostitution, as above defined, were it not for other concomitant causes. Among these are enumerated vanity, or the desire of glittering in fine clothes, idleness, domestic sorrows, and the unkindness of parents or step-parents, want of education and poverty, stringent marriage laws, and, lastly, spirit-drinking.

Vanity, or the desire of living in splendour, is, doubtless, one of the chief causes of prostitution among a certain class of women. This cause works most among the most

refined of them, and is said to be a common cause in Paris, London, and large towns, where there are many wealthy persons.

Puritanism sometimes forces women into prostitution, especially in America, from the harsh measures dealt out to the first yielding of the young girl.

The habit of *spirit-drinking* is a cause, as it is a cause of so many other misfortunes to the human race.

Want of education has been found to be a most frequent antecedent of prostitution. Thus, of 4470 prostitutes, natives of Paris, 2332 could not sign their names—a circumstance which, in Paris, where education is gratuitous, shows how careless their parents had been and how little their children had to thank them for. This want of education among prostitutes is common to most towns, except Edinburgh (Tait).

Illness, or the desire of living without industry, is the antecedent of much prostitution. It must, however, be remembered that the idleness of many women resembles that of the Irish cottier, who is lazy in Ireland, where his labour is badly paid, but industrious in America, where his services are valuable.

Poverty.—Duchâtelet says: "Of all the causes of prostitution, particularly at Paris, there is none more active than want of work and poverty, unavoidable consequences of insufficient wages." In London and other large towns in this country the same cause is a well-known antecedent. Women's wages are very low. In a report by Dr. Edward Smith to the Privy Council, we find the wages of needlewomen, "the lowest class included in my inquiries. Their average income is 3s. 11½d. per adult per week." This low remuneration of labour is caused by over-population, and the paucity of employments for women. If any person should say that the appetite for sex is more conducive to prostitution than is poverty, I reply, that this appetite, if women were in good circumstances, might lead to licentiousness in many cases, but not to prostitution, as defined on setting out.

Decrease of marriage and stringent marriage laws.—It is well known that the proportion of marriages to population has of late years been decreasing, partly from the fear of over-population where families are so large, partly from the stringent laws of marriage which prevent divorce, except for disgraceful conduct. From 1796 to 1805 there were 1716 marriages in 10,000 women, and in 1836-45 there were 1533 to 10,000. This holds for Paris, Hamburg, and other towns. Paris is said to have 1 illegitimate birth to 3 legitimate. Sir W. Wyld tells us that Munich, in 1838, had 270 more illegitimate than legitimate births. If divorce were more facile, probably marriages might become more numerous and even happier than they are on the average at present. In Prussia they are frequent.

Diseases of prostitutes.—The evidence of Duchâtelet, Acton, Lippert, Baré of Nantes, and others, shows incontestably that the health of prostitutes is above that of women in general. The only two diseases which infect them peculiarly being syphilis and scabies. Mr. Acton says of the girls in London that they are "picked lives," that they lead a dissipated life for two, three, or four years, and then marry, or take up some other occupation; about one-fourth, he calculates, of their number leaves the trade every year. The same story is told by other observers. Duchâtelet speaks of the "iron health" and stoutness of the majority of the girls, compared with that of many poor mothers of families or seamstresses, who toil from morning till night to get a bare existence.

As to the details of their diseases, *hoarseness* is frequently observed, and is attributed in general to their exposure to the cold, when insufficiently clothed, to spirit-drinking—a common cause in this country, and sometimes to syphilitic affections of the vocal cords.

Obesity is frequently remarked, and is attributed to the lazy life led by the majority of them, and the abundance of food they consume.

Diseases of the anus are not unfrequently found in Paris

and Italy, although uncommon in London, and recto-vaginal fistula, especially in those of a scrofulous constitution. Tumours and abscesses of the labia majora are frequent. In most cases, however, the aspect of the genitalia of prostitutes would not distinguish them from married women: a few cases are on record where they have been mistaken for virgins.

Sterility.—The sterility of prostitutes is a marked and important feature in the phenomenon of prostitution. Were this not the case there could scarcely exist such a trade as prostitution, since, if prostitutes were frequently pregnant, the poorhouses would become crowded by abandoned infants. It appears, according to Duchâtelet, that there was not much more than one child per thousand prostitutes per annum in Paris, when he made inquiries. The cause of this sterility cannot be said fully to have been made out. It would appear that excessive sexual intercourse produces in the female sex, as it does in the male, imperfect elaboration of the secretions necessary for impregnation. In addition to this, probably ovaritis and inflammation of the uterus. The mortality of the children of prostitutes is enormous.

Cancer of the womb is rare among prostitutes. Lippert of Hamburg had not seen a case in eleven years among them: but as this is a rare disease among women, and usually comes on at the menopause, this is not so remarkable. Some persons have said that cancer of the womb is more common in old maids than in prostitutes, but this is not clear. Prolapse of the womb is uncommon among the class.

Hysteria is extremely rare among prostitutes. Lippert says they have scarcely a trace of it. Duchâtelet and others endorse this observation. This absence from nervous disorder is probably explicable by the fact that restrained sexual emotions are undoubtedly a very frequent cause of hysteria. I agree with what Mr. Holmes Coote is reported to have said in the Medico-Chirurgical Society, February, 1859—viz.: "No doubt incontinence was a great sin; but the evils connected with abstinence were productive of far greater misery to society; any person could bear witness to this who had experience in the wards of lunatic asylums." Sir B. Brodie also is reported to have said in the Birmingham Social Science Meeting that "the evils of celibacy were so great that he would not mention them: but that they quite equalled those of prostitution." I think that Dr. Carpenter's views that "the development of the individual is opposed to the reproduction of the species," is a physiological law which does not hold for the larger animals, however it may for the insect tribe. Many animals become rabid if deprived of sexual congress. Of course excesses are most injurious, but they are not nearly so common as the effects of abstinence as seen in Europe. We all know—*e. g.*, what hosts of unmarried women there are.

Veneral diseases are connected with prostitution just as lead colic is with the painter's trade. These diseases are very important, both become frequently the cause of death in the male sex, and also from the amount of time lost and mental distress they occasion to the adult population of this and other countries. It has been calculated that there are about one and a half millions of such cases in Great Britain annually (Holland), and 50,000 cases are supposed to be seen in London hospitals yearly. One in five of the troops, one in three of the merchant service, are said to be affected annually (Acton), also half the surgical out-patients at some hospitals. The same story holds for New York (Sanger). As to the fatality of these diseases, there were in 1854, thirty-four deaths in the Midi Hospital for men in Paris; only two of these deaths was from stricture of the urethra—a complaint which proves frequently fatal in non-venereal hospitals. Prostitutes, however, very rarely die of venereal diseases. Thus, in 1854, in the Lourcine Venereal Hospital in Paris, with 276 beds, not a single death among the female patients was attributable to venereal disease. The French plan of regulating prostitution has very much lessened the extent and gravity of

these diseases in some continental towns. Thus, in the town of Nantes, Dr. Baré says, that syphilis is extremely mild, tertiary symptoms are not seen, secondary symptoms are rare. In Belgium, out of 30,000 troops, there were in 1855 only 200 cases of venereal disease. In Hamburg, Dr. Lippert reports the disease as extremely mild. All this is attributable to weekly inspection of the prostitutes in these towns, also to their not being in the habit of drinking spirits. In Paris, there are ten physicians and two assistant-physicians appointed to examine the women, and in 1854 no less than 155,807 examinations were made. Great care is taken that girls under sixteen should be removed from the streets. This disgraceful negligence of society is often found in the towns of Great Britain. In Hamburg, with 180,000 inhabitants, three medical men examine all the prostitutes weekly. They are under police control.

Various arguments have been used for and against the toleration system of the Continent and the examination of the women. Most continental writers deny the right of the woman to spread contagious disease, or to walk openly in the streets for prostitution. Writers in England and America again see the other side of the question more clearly. They observe that the liberty of the female sex is already too restrained, and that men are not interfered with under similar circumstances. They, therefore, deny the right of the Corporation or State to do anything more than prevent violation of decency and order. For my own part, I incline to the latter opinion, as being, on the whole, the less of two evils. While, however, opposed to the Continental custom of *police* supervision and regulation of prostitutes, I think that a great effort should be made to lessen the frequency of these pests of mankind, venereal diseases, so common in this country.

To accomplish this it might be possible to appoint a number of medical officers in each of our large towns to examine all public prostitutes who *voluntarily* presented themselves at certain offices or dispensaries for the purpose, to send the diseased to hospitals, where, on entering, they should be obliged to sign a declaration that they will not leave until declared free from contagion, and to give a certificate of health to the healthy. These officers, I think, should be appointed by the different town corporations. About thirty would be required for London. Mr. Acton has done much to facilitate the introduction of such a measure, and Mr. Holmes Coote has justly observed (debate above cited) that the manner in which venereal diseases are spread abroad in London is "disgraceful to the Legislature." This opinion, however, is by no means universal in this country, unfortunately for the health of its unmarried population, now so numerous. Thus Mr. Solly is reported to have said, in the above cited debate, that, "Far from considering syphilis as an evil, he looked upon it, on the contrary, as a blessing; and believed that it was inflicted by the Almighty to act as a restraint upon the indulgence of evil passions." Such is indeed the opinion of a large number of individuals in this country and America. Venereal diseases are regarded by such persons as a means of driving the young into matrimony. In Ireland the effect of such early marriages has been to pauperize the whole country, and to render it a bye-word throughout Europe for misery and human degradation. The agricultural counties of England are not in much better case. There we hear of labourers with eight, ten, or twelve shillings a week, with large families. Can we wonder their daughters are obliged to sew for 4s. 11½d. a week and die of consumption (Ed. Smith), or to become prostitutes for a living. This is the end of such advice as thoughtless and ignorant societarians are apt to give. The blame for becoming a prostitute should rest with such parents and those who give them no better advice; yet, as is observed by Mr. J. S. Mill, in his "Principles of Political Economy," "Whilst a man who is intemperate in drink is discountenanced and despised by all who profess to be moral people, it is one of the chief

grounds made use of in appeals to the benevolent that the applicant has a large family, and is unable to support them. Little advance in morality can be expected until the production of large families is looked upon in the same light as drunkenness." There is no doubt that, as Sir Benjamin Brodie remarked at the Birmingham Social Science Meeting, the remedy for prostitution lies chiefly in early marriages; but it is only in France that the poorer classes marry young and yet have small families. Here, and especially in Ireland, they have as many as they can, and consequently starve. Probably, however, were divorce easily obtainable, as in Prussia or in Indiana, U.S., in which latter place six months' notice of incompatibility of temper is all that is required, persons would hesitate before bringing so many unfortunate children into existence, to struggle, as they do now, for a bare and joyless living. As we have seen, a most important cause of prostitution is the lowness of women's wages. They have far too few employments. They ought therefore to be encouraged, as well as permitted, to attempt any trade or profession they have a mind for. Should they fail in such attempts, it will be time enough to say that women are fit for nothing but to be wives and mothers. Both of these, it is to be hoped, all may have the chance of being; but life is long, and they have plenty of time for industrial pursuits before and after they give birth to one or two or three children, which is all that the over-peopled condition of this and other countries similarly situated renders advisable they should have. Again, some women have no children, and many have admirable intellects, and could carry on trades or professions or business with great advantage to themselves and to society. Poorer women might learn trades or businesses, and the upper classes of women professions or businesses. Doubtless many would fail in such professions; but they would also sometimes succeed well in both law and medicine. A surgeon might then take a partner for life who would be able to cooperate in his efforts. Any other view of the question than this is, in my opinion, when stripped of declamatory phrases, only a way of getting woman's services cheaply, as they are obtained at present, and forcing them to be, through civil disabilities, the servants of men—a branch of the old tyrannical views of human society, which is dying off, *pari passu*, with the abolition of slavery and the decay of aristocratic ideas, throughout Europe and America.

Mr. DUNNE said—I have listened with great pleasure to the able paper of Dr. Drysdale on this most important subject. Amongst the causes of prostitution I think the author has omitted one—*viz.*, seduction. This is certainly in a great many cases the first step towards prostitution, for there are in this as well as every other large city a certain class of men who make a boast of how many girls they have seduced. For this class of men no kind of punishment can be too great; the law might compel them either to marry or allow the unfortunate girl enough money to live in a respectable manner, and if they refused to do this, some other severe punishment should be inflicted upon them. Society even might do much to remedy this evil—*e. g.*, refuse to admit within its circle any man who could be proved to be a seducer. He agreed completely with the author, that the scarcity of employment for women and the low rate of wages was another cause for prostitution, particularly in this country, where there are so few trades and professions open to women, and there being a large excess of female population, causing the supply to exceed the demand. To remedy this would be easy, throw open all trades and professions to women and encourage their employment as much as possible; also encourage emigration as much as possible to those countries where there is an excess of male population. Another cause is, I think, "Nymphomania." Again, a great many women take to this calling as a mere matter of business, from the fact of seeing others walk the streets, dressed as these women are, whilst they, as respectable women can scarcely obtain food upon the miserable pittance they earn. Take as an

illustration, a poor woman who has been sewing as fast as her fingers and strength will allow at shirts or mantles, earning perhaps a shilling or a little more a day, returning home at night completely worn out with fatigue, and seeing these gay flaunting creatures in their fine dresses, whilst she poor girl, in her well worn gown and boots, is perhaps suffering the pangs of hunger. She may perhaps hear at the same time of the fabulous sums of money earned by these women through prostitution, more pounds in a day, than they earn shillings in a week. Is not this a temptation which many of us would find difficult to resist? Are we not all more or less envious of our neighbours? The only plan would be to try to reduce the wages for the time of prostitutes, and let the women of England refuse to admit into their society men who are the associates of prostitutes. In London there are, according to Dr. Drysdale's account, 12,000 prostitutes—I think that number underrated; but let us now examine what amount of hospital accommodation there is in this large metropolis for these most unfortunate women. I believe I overstate the amount when I say there are only in all the hospitals in London—"Lock Hospital" included—200 beds. Is this accommodation sufficient? What is the consequence, if one of these unfortunate 12,000 women, become diseased—if she is very fortunate, she may be able to get into the hospital; but if the beds are full what is she to do? She must either go into the workhouse or become an out-door patient at one of the hospitals or dispensaries, or she might perhaps be able to afford to go to some private medical man; but this class of women as a rule are very improvident, and therefore cannot afford the latter. How are they then to live during the time they are diseased? Can they obtain employment of any kind? They are still obliged to follow their old calling, and by so doing propagate the disease to a most fearful extent. If they do not do this, their only alternative is to starve, beg, or steal. Any man who has visited the out-patient department of any large hospital or dispensary must be struck with the large number of venereal cases he sees—I think I might say that every other one is venereal. I know that at the dispensary I am connected with, the number of cases I see yearly of this disease are very great, and it constantly occurs to my mind how this evil can be remedied. The only way I can propose is (yet not liking to interfere with the liberty of the subject) that all prostitutes should be placed under police control for some years to come, at least until the present numerous venereal cases are diminished in this country. I agree with Dr. Drysdale that medical men should be appointed in any large city to examine women, but I differ from him in thinking that instead of such an examination being voluntary, that every woman should be compelled by law to present herself for examination at least once in ten days, and if at any time she should find there was anything the matter with her she ought immediately to go to the medical officer of the district to be examined. If, upon examination, there was found any venereal or contagious disease, she should be sent immediately to the Lock Hospital, each district to have its own Lock Hospital, and the medical man who examines the women in the district to be the medical officer of the hospital. The woman ought to be compelled to remain in the hospital until she is quite well, and during her residence, then would be the time to try to reform her, everything should be tried to wean them from their former mode of life. A trade or profession should be taught, and those that cannot read or write to be taught to do so. When they are well enough to leave the hospital try to find them some employment, so as to prevent them having the necessity of falling back upon their old mode of obtaining a livelihood. By these means, I think, much good might be done, this dreadful scourge of syphilis might be diminished in this country, and what an amount of happiness this would produce in very many families, also what a saving to the country, and how many unfortunate new-born infants might be saved from an early death, or a life of misery!

Dr. TILBURY FOX—Mr. President, reference has been made by Dr. Drysdale in his paper to a statement supposed to have been made by Dr. Lankester, to the effect that of every 30 women met with in London streets one had committed infanticide. This Dr. Lankester has told me was wrongly reported by the newspapers, and that he simply quoted the observations of a French Abbé, who wrote on the subject.

Mr. HOLMES COOTE—I acknowledge that I made use of the expressions which I am reported to have uttered at the Medico-Chirurgical Society on the occasion referred to, and I still entertain the opinion that there are worse evils appertaining to human weaknesses than prostitution. I happen to possess opportunities of witnessing the fact, that among the young there is no cause of insanity more common than indulgence in habits which I will not further particularize even in a medical society, but which are known to result in the most complete bodily and mental prostration. Idleness and vanity may rank among the causes of prostitution in women, but occupation alone will not suffice to prevent it. There is a peculiar condition of the mind when the passions become excited, and women thus affected seek the opportunities of going astray. After a period of repose in a proper asylum the mind recovers its equilibrium, and the patient returns to society; but she is liable to a relapse. This condition I have seen both among the married and the unmarried. With regard to the question of trying to check the spread of the venereal disease, I say here that which I said before the Venereal Commission—namely, that in my opinion legislative enactments are required. Women should not be allowed to quit the hospitals partly cured. It is known that at Portsmouth and other naval stations they leave their wards and crowd down, still diseased, to meet the seamen of a ship just paid off. In the London hospitals they leave the wards at certain periods of the year, such as Christmas, for purposes of festivity. With reference to men, it is impossible to institute a system of inspection. Even in the public services, such an order would lead to discontent, breaches of discipline, and concealment. Moreover, what classes are to be included in such inspections. Is it to comprise officers? But I quite approve of the inspection of all houses where prostitutes dwell, and of the examination and registration of such women. The spread of the venereal disease is a very grave evil. It makes its appearance, unhappily, in homes where it never should be known, and falls upon the innocent young mother and her offspring. I am glad that this subject has been so fairly discussed before this learned Society, and that the members have the moral courage and philanthropy to grapple with this evil. My opinions are the same as those which I expressed at the Medico-Chirurgical Society in 1859, where, however, I heard from one or two of the members some sentiments on that occasion of an opposite character, which, to say the least, were startling.

Mr. ACTON—Mr. President, it gives me great pleasure to find that the author of the paper has taken up the subject of prostitution. It marks a great progress in this question, since a few years ago it would not have been possible to bring this question before such a society as the Harveian Society of London. One of the recommendations I gave to the members of the Venereal Diseases Commission, when examined by them, was that they should not attempt to go too fast. They should, I think, commence by attempting to render the army and navy less overrun by venereal diseases before they attempt any measures to restrain the disease in civil life. If this suggestion be carried out in the army and navy, I trust it will be done well, not negligently; for if carried out well it cannot fail greatly to lessen the amount of these diseases in the service. With regard to examinations in civil life, I am not an advocate for indiscriminate examinations, such as those practised in Paris. For example, were such a

case to happen in London as I am about to relate, there can be no doubt that the puritan party, who are most opposed to any such prevention of venereal diseases, would raise such an outcry that in all probability the practice would have to be given up. When in Paris some years ago I visited the *Dispensary*, and was admitted to the examination of the prostitutes, which, as you know, is carried on to an immense extent. One of the patients examined was pronounced sound by the examiner. I said to him, "Don't you think that girl is a virgin?" He replied, "It is possible; but that is not our business." It turned out from inquiries I made that this girl had quarrelled with her mother, and had gone straight to be enrolled as a prostitute and examined. Now, it almost seemed as if Government sanctioned the girl in taking up prostitution for a livelihood. I do not know what became of her. She may have married a duke or some person in high life for anything I know; but I repeat that such a case occurring in London could not fail to excite the zeal of that portion of the religious party who are at present sulkily acquiescent, but may easily be roused. Two or three questions have been mooted this evening with regard to prostitution which I cannot quite coincide in. I cannot think that want of education alone or poverty can be such frequent causes of it as has been supposed. Thus it is not low wages that causes prostitution so much as the desire of getting money easily—a failing which I think is common in men as well as women. When a half-starved or ill-regulated woman sees that by prostitution she can make twenty guineas a day and wear fine clothes, I think there is not much wonder that she often prefers it to working. It appears that in the streets of Melbourne, where every woman that wishes it can earn a good living, prostitution is even more rampant than in London; and with regard to emigration, many of the women who have been sent to Australia do not like work. It is a well-ascertained fact, too, that in Paris the students do not so much take mistresses who are idle; they prefer those who can earn good wages, in order to have less trouble with them. It is the temptation of living easily in most cases that conduces to prostitution, and also, as Mr. Coote truly observes, in some cases the sexual passion is very strong in women. Whatever the virtuous portion of society may wish, prostitution will go on. Mr. Dunne has spoken of seduction being a great crime, and no doubt this is true; but how are you to punish the man for this? I remember when young in my medical career, accompanying a deputation composed chiefly of clergymen on the subject of prostitution to Lord Brougham. On one of the party proposing to the noble lord that a still more stringent law should be passed punishing the seducer, he asked, "But are you sure, gentlemen, that it is always the man who seduces the woman?" I quite agree that no sin can be greater than that which men about town are known to boast of—viz., the sedately setting down to seduce as many girls as they can. Some men have seduced many girls. Would Mr. Dunne or others have them marry them all? I am afraid punishment for such persons does not come in this life. The old parish law ought to be remodelled. A far greater sum should be exacted from the father of an illegitimate child, and the parish should be empowered to recover the sum from the father. My opinions are to be found in the *Journal of the Statistical Society* (1860).

The PRESIDENT—The author of the paper has asked what is the pathological reason of the sterility of prostitutes. It is, I believe, as follows:—Prostitutes are subject to amenorrhœa and dysmenorrhœa caused by frequent sexual connexion. The same symptoms are noticed in other women who practise masturbation. In post-mortem examinations of prostitutes there has been observed thickening of the indusium of the ovaries. There is also a spasmodic closure of the os and cervix uteri from the repetition of the orgasm which opposes the entrance of the male secretions into the uterus. Such is the explanation of their sterility. Although not

closely related to the question, I may mention that I have once seen an unbroken hymen in a prostitute. She was a well-known woman and lived in great splendour. In this case the hymen was quite elastic, and the appearance of the genitalia was that of a virgin. The subject of prostitution cannot be too often discussed. I believe that, although this is not one of the large societies, much good may result from this evening's debate.

SURGICAL SOCIETY OF IRELAND.

Dr. WILMOT, President of the College, in the Chair.

THE Society met on Friday evening, the 19th of January.

FOREIGN BODY IN THE KNEE-JOINT.

Dr. BENSON read the following paper by Dr. Wilkinson of Limerick on the removal a foreign body from the knee-joint:—

October 5, 1865: John Dwyer, aged 65 years, admitted into the County Limerick Infirmary this day; has enlargement of the right knee for the last six months.

For several years past, he has felt something in the joint which he was able to move from the inside to the outside of the knee, but which did not interfere with either his walking or his work until last June. Previous to admission he had repeated blisters applied to the knee by the advice of country practitioners. On examination, a foreign body could be felt in the joint, which was movable from the inside to the outside, but which could not be fixed for any length of time in one position without giving acute and intolerable pain.

An attempt was made to remove it from the joint by subcutaneous section, which failed from the size and irregularity of the foreign body. On the withdrawal of the knife a large portion of the fluid of the joint escaped, after which the size of the foreign body could be more distinctly ascertained at the outside of the knee.

It was then thought advisable to cut down by simple incision on the foreign body and remove it. The incision was made at the posterior edge of the vastus externus tendon, between it and the tendons forming the external hamstrings.

The foreign body was $2\frac{1}{2}$ inches in length, $1\frac{1}{4}$ inches in breadth, $\frac{3}{4}$ of an inch in thickness, of a flat irregular surface, and weighed four drachms and ten grains.

After the operation a compress and bandage, wet with cold water, were applied to the knee, and he was ordered pulv. Doveri and hydrargyrum c. creta, with the view of preventing inflammation of the joint. On the third day after the operation the knee was as large as before it, and was quite soft and fluctuating and free from redness, pain, or inflammation; after that, the enlargement began to decline, and a free watery discharge came from the wound.

The enlargement of the knee was formed by a soft fluctuating fulness at each side of the tendon of the rectus muscle; and also a small fluctuating tumour, about the size of a pigeon's egg at the posterior and inferior part of the inner condyle, which could be reduced by pressure, and which has entirely disappeared since the operation. The inner condyle of this femur is much larger than that of the other leg, and the knee is bent inwards.

October 18th: He has been walking about the wards for several days, the wound not healed, but looking well, and a thin watery discharge coming from it. He left the Infirmary on the 18th without notice, having heard of the dangerous illness of his sister.

Dr. BENSON said that as the patient had left the hospital before the results were known he had written to Dr. Wilkinson to inquire if he had heard anything since of the man. It appeared that the patient had fallen under the observation of Dr. Riordan, to whom Dr. Wilkinson wrote on the subject, and from whom he received the following reply:—

“Bruff, Jan. 14, 1866.

“MY DEAR DOCTOR,—I would have answered your letter

before this about Dwyer, but was unable to ascertain all particulars about him until yesterday. For some time after he left the hospital he placed himself under the care of a quack who applied all sorts of ointments. Finding that he did not succeed, I was requested to visit him about the end of November. I found a large abscess occupying the entire ham, which I opened, and which continues still discharging. The sinus through which the foreign body was extracted continued open until about a week since. There was great redness and pain inside the knee, during the entire month of December. After that all pain ceased; the knee is now bent and incapable of being straightened. His health is much improved, and he has been able to sit up for the last week. When I first saw him the entire leg was very much swollen and required to be bandaged. Any further information about his case I will be able to give you, as he is living with his son in my district.—Believe me, very sincerely yours,
“D. RIORDAN, M.D.”

Mr. PORTER believed the practice usually adopted by the surgeons of Dublin was not to meddle with these foreign bodies unless they produced a great deal of inconvenience. When they were very small, they tried to bind them in a place where they would not produce much inconvenience, but when they had grown to a large size they must remove them. He never removed but one, and he then adopted the plan of Mr. Fergusson. He removed the skin to one side, and then cut down on the foreign body and removed it at once. Others might approve of the mode adopted by Syme and Liston—viz., to enter a knife at some distance from the synovial pouch, then having opened the latter subcutaneously allow the foreign body to pass into the areolar tissue, and there to remain until the wound has healed. A great deal depended on the after-treatment of the patient. If the joint could be kept at rest and the inflammation subdued, in many of these cases he believed no bad result would follow.

Mr. TUNNELL said he had removed foreign bodies in two cases of this kind, but the bodies were different in appearance from the specimen presented. They were cartilaginous and smooth on one surface, having an irregular nodulation on the other resembling greatly the mouth of the ray. In each of these cases the foreign body was like an oblong half chestnut, and was removed by a free valvular incision, slipping out the foreign body at once. Treatment was adopted previously as well as afterwards—viz., the individual was confined to bed for a considerable time before hand, and kept on low diet, and everything was done to favour the avoidance of inflammatory action afterwards. In both cases the wound healed by the first intention. He subsequently kept the patients a long time in bed after the operation before he let them get up, fearing that the action of walking might cause the recently united surfaces to open.

Mr. B. W. RICHARDSON said that he assisted his colleague, Dr. Walsh, in removing from the knee-joint of a young woman in the Adelaide Hospital, a foreign body similar to, although smaller than the present specimen. It was, like it, very nodulated over the whole surface. As to who was entitled to priority for the removal of foreign bodies by the subcutaneous method, it was clearly proved by Mr. Adams of London, that M. Dupresse Chassaigne anticipated both M. Goyrand and Messrs. Liston and Syme. M. Goyrand's first operation was performed on the 14th of September, 1840, whereas M. Chassaigne did his in May of the same year. Although Goyrand gives the credit of the idea of the operation to M. Guérin, the latter gentleman himself does not claim it, for he mentions that Dupresse Chassaigne is entitled to the honour. Chassaigne's operation was similar to the procedure with which Mr. Liston's name was subsequently associated. After Chassaigne had fixed the loose body between the index finger and thumb, he thrust a fine cataract needle under the skin, tore the capsule round the foreign body, withdrew the instrument, and fixed the parts with sticking-plaster in the situation in which he put them, and which he tightened round the foreign body covered by the skin. He then bandaged the limb from the foot to the knee, kept it extended, and left

it so for eight days, at the end of which time the body was found to be adherent where he had fixed it. The Society will perceive that this operation of Chassaigne's was similar to the one which both Mr. Syme and Mr. Liston claimed credit for originating, although it was performed many months prior to their operation. I need scarcely remind the Society that M. Guérin's operation consisted in removing the foreign body at once, whereas M. Goyrand left it under the skin for several days, and then removed it.

Dr. BENSON said the same operation was attempted here, but from the great size of the foreign body it was not carried out.

Mr. RICHARDSON said that in the case of Dr. Walsh, which he alluded to, Goyrand's operation was the one had recourse to. The case did remarkably well. The foreign body was decidedly in the joint, and presented that nodulated and irregular appearance occasionally observed. Sometimes, however, they were very smooth.

Dr. FLEMING said that these bodies, when removed from the knee-joint, usually presented features such as were described by Mr. Tufnell.

Dr. GRIMSHAW asked if the chemical constitution of the specimen had been ascertained?

Dr. BENSON replied that he had asked Dr. Benson, junior, and Dr. John Barker to examine it that day, and they found that it consisted of phosphate of lime, with carbonate of lime, and an animal basis very similar to that of bone.

Dr. FLEMING said that when he saw this specimen on the preceding day it occurred to him that he had a curious calcareous deposit which presented several of the characteristics of the present specimen. He had therefore brought the preparation with him, consisting, as they would observe, of a very considerable calcareous deposit, which was removed from the bladder of a woman who was admitted into the Richmond Hospital labouring under all the signs of stone in a most aggravated form. When the woman applied at the hospital she had a portion of the substance in her hand, which he thought was a piece of bone. He did not credit the statement which she made when she applied for admission, but was rather inclined to think that she was one of those persons with a morbid taste, and had herself introduced this substance into the vagina. On sounding her it was found that there was within the bladder a solid resonant body, which communicated to the sound, the signs a stone would give. She was examined by the late Mr. Hutton and Dr. McClin- tock. The ordinary operation was performed—viz., dilatation and section of the wall of the urethra. This not sufficing, he next employed a strong lithotrite, but eventually the bladder had to be opened above the pubes, and they then found within it a very large amount of this remarkable deposit.

Dr. BENSON asked if it was like the specimen now before the Society.

Dr. FLEMING replied that its composition was like what Dr. Benson had described the present specimen to be; but there were scattered through it some portions of oxalate of lime.

Dr. GRIMSHAW said he had examined the specimen produced by Dr. Fleming, and found it to consist of phosphate of lime and animal matter. Some London gentlemen had expressed an opinion that it was more like bone than he considered it to be. He went over it six times, and in every instance he got oxalate of lime, but all in different proportions. Some parts contained a great, others very little, and it was possible that the portions given to the London gentlemen contained none at all.

Mr. RICHARDSON observed that Mr. Redfern had got crystals of oxalate of lime in diseased joints.

Dr. GRIMSHAW—There are some portions of the calculus that resemble the concretion which Dr. Benson has shown much more than others.

Mr. PORTER thought from what Dr. Grimshaw said, it appeared that it contained oxalate of lime. Now, a mixture

of phosphate of lime and oxalate of lime was an unknown form of calculus, and they should therefore feel much indebted to Dr. Fleming for allowing them to see such a strange specimen.

Dr. FLEMING said that he constantly met with combinations of phosphate of lime and oxalate of lime in certain conditions of the bladder and kidneys.

Mr. PORTER knew that when oxalate of lime lay in a diseased bladder it became coated with phosphate, but he repeated that it was an unusual form of calculus to find it mixed up in the way in which it appeared to have been in the specimen which Dr. Fleming exhibited.

Mr. B. WILLS RICHARDSON then read the following communication

ON THE REAL SHORTENING OF THE LIMB IN THE THIRD STAGE OF HIP-JOINT DISEASE.

The preparation I exhibit to the Society this evening illustrates a pathological condition of the hip, which is one of the causes of the shortening of the limb in the third or advanced stage of morbus coxæ, a symptom that has given rise to some discrepancy of opinion. I shall here observe that I exclude from my observations any notice of chronic rheumatic arthritis, a totally different disease from the one before us.

In the work of Sir Benjamin Brodie on diseases of the joints, where he describes the symptoms of morbus coxæ, it is stated that in the very advanced stages of the disease when the head of the femur has been completely destroyed by ulceration, there is nothing to prevent the muscles from pulling the bone upwards. This kind of case he compares to a case of fractured neck of the thigh bone. The foot may be rotated inwards, but, if left to itself, it generally is turned outwards. Of course, if the head of the bone has been completely destroyed, there is nothing, as Sir Benjamin Brodie observes, to prevent the muscles from drawing the thigh bone upwards; but I would remind the Society that several examples of another description of case, have been recorded, in which the head of the bone was not completely destroyed, although much reduced in size, by caries, and which diminution in its calibre was coexistent with elongation of the acetabulum in the upward direction, apparently the result of the combined influence of pressure of the head of the bone and disintegration of that cavity. Now in cases like these, there is likewise real shortening of the limb, and the foot may be either inverted or everted. The specimen that I present to the Society is not similar to the first description of case alluded to by Brodie in the observation I have referred to, because in it the head of the bone retains its normal rotundity and shape, although much altered in its internal structure, the disease concentrated its action on the bones forming the acetabulum, leaving scarcely a vestige of its brim, the absence of which permitted the head of the femur to pass upwards on the dorsum illi, to just above the sciatic notch, where it was finally lodged.

In other cases Brodie further remarks, "the limb is shortened; the thigh is bent forwards; the toes are turned inwards; and there is every symptom of a dislocation of the hip upwards and outwards." I believe the general impression at one time was, that the real shortening of the limb in the third or advanced stage of morbus coxæ most frequently depended upon dislocation; but the opinion seems to be prevalent now, that luxation is not the most frequent cause of the real shortening of the limb in hip-joint disease. Our College Museum only affords three specimens, and it has been stated that there are not many specimens of this displacement in the large museums of London. We might be led, however, into error by such negative evidence, because, when museums contain a few specimens similar in their nature, economy of museum space forbids the mounting of other preparations of the same kind, so that many duplicate specimens are frequently rejected by curators.

The question regarding the real shortening of the limb having been reopened within the last few years,

I thought myself justified in taking advantage of the specimen before you to draw the attention of the Society to the point, and which I am sure will be considered a very legitimate subject for discussion.

It is not my intention to weary the meeting by reading the day-to-day reports of the patient's case, and I shall, therefore, merely confine myself to a short outline of her clinical history.

N. W——, a pale, thin, emaciated girl, was admitted into the Adelaide Hospital on the 1st of March, 1864, for disease of the right hip-joint. The right lower limb was shortened about an inch and a-half, and the foot and leg were advanced, the toes turned inwards, and the limb partially crossed over the opposite one. It was much wasted. There were no symptoms to lead us to think that abscesses then existed.

Our attention was next given to the state of the chest. Unfortunately it afforded indications of disease, percussion having elicited dulness under the left collar bone, where the respiration was more bronchial than natural.

She suffered much from pain in the hip. Her pulse was exceedingly rapid, and she had occasional diarrhœa.

She was put upon an extra, but carefully regulated, diet, and had a liberal allowance of wine. Medicinally she was given, whenever there were no contraindications, cod-liver oil with syrup of iodide of iron, and occasionally the liquor of the pernitrate of iron, bismuth, &c.

Under the mode of management pursued in the case, notwithstanding its unfavourable nature, she improved so much in a few weeks that she was able to get up and move about with the assistance of a crutch, and in a little further time she was allowed home to the country. We heard nothing more of her for some weeks, when at last she applied to the hospital for readmission. This was on the 11th January, 1865. Wretched as her condition was when she was first admitted, she was now in a much worse one; she had lost the little flesh she gained when she was formerly with us, and was again extremely emaciated, greatly blanched, and suffered much agony from the hip, where the great trochanter protruded through a large opening in the soft parts, and which also exposed a considerable portion of the outside of the shaft of the femur. Through this opening pus constantly oozed. Matter also burrowed down the outside of the thigh reaching almost half way to the knee-joint. The knee was semiflexed, and it and the foot were turned inwards. The shortening of the limb was about two inches.

She had a troublesome cough and sometimes diarrhœa. There were the physical signs of a cavity in the left lung: and dulness on percussion and crepitus were well-marked under the right clavicle.

I will not occupy your time with the daily notes of the progress of the case to its fatal termination; suffice to say, that we tried various remedies for her thoracic and abdominal symptoms, and gave her whatever stimulants we thought she required. As I have just mentioned, matter had reached half way down the thigh. If possible, to prevent further burrowing I passed a piece of drainage tube into the lowest part of the abscess, and brought the end through the opening at the trochanter. Pus drained freely through the tube, apparently almost as fast as it was formed.

With such a complication of disease her tenacity of life was extraordinary, the vital powers, however, were unable to sustain her longer than the 3rd July, 1865, when she died worn out by the suppuration at the hip, as well as by the thoracic disease.

The post-mortem was made the next day. Cavities existed in the apices of both lungs. The hip was then examined. The acetabulum, as the preparation shows, was completely destroyed by caries, scarcely any trace of its brim remaining. There was nothing, therefore, to prevent the head of the thigh bone from passing upwards to the dorsum of the ilium, where it is lodged just above the sciatic notch. The head of the bone retains its globular form and original size, although it is much altered in its interior, the

cancelli being to a great extent destroyed, their place being occupied by a sizo looking substance.

In addition to external abscesses, suppuration had taken place internally, corresponding to the pelvic surface of the acetabulum and the bone above it, to near the brim of the true pelvis. Although there was no direct communication between the external abscesses and this deep one, it is possible they may have indirectly communicated through the diseased bone which is much rarified by caries. To the naked eye, however, an opening was not apparent. Surgeons, however, are aware that cases have been recorded proving that suppuration may occur corresponding to the pelvic surface of a diseased hip-joint without any communication whatsoever externally, a deeply interesting practical fact, when excision of the hip-joint is in contemplation.

I now come, Sir, to the question, and the one which has induced me to bring this specimen under your notice—What is the most frequent cause of the real shortening of the limb in the advanced stage of morbus coxæ? Does it in the majority of cases depend, as it was until a comparatively recent period thought to do, upon dislocation of the head of the bone upon the dorsum ilii, or does it more frequently arise from elongation of the acetabulum in the upward direction, coexistent with disintegration and consequent diminution of the head of the bone, the latter still remaining in the altered cavity: or is it most usual to find it the result of an alteration similar to the first description of case alluded to by Brodie? This is the question I am anxious to have the opinion of the Society upon. It has been reopened, as I have already mentioned, within the last few years, and it is desirable that statistical evidence bearing upon the point should be collected. It is to be hoped that the hospital surgeons present will give us the results of their necroscopic examinations of the fatal hip-joint cases which came under their notice, and in which there was real shortening of the limb. Post-mortem examination is peculiarly necessary in such cases, because we may be deceived by measurements, for the shortening of the limb may decrease as the case progresses, owing to the absence of the head of the bone from the acetabulum, allowing the pelvis to descend further than it otherwise would do. Before I sit down I shall again observe, that this case gives us a useful warning regarding excision of the hip, and the caution necessary for endeavouring to ascertain if there is any internal pelvic mischief before the operation is had recourse to. In it not only was the acetabulum diseased, but the disease also extended through the whole depth of the bone corresponding to the cavity, as well as to the adjoining bone, giving rise to suppuration internally. It is scarcely necessary to say that excision with such a complication present, would further jeopardise the life of the patient.

Mr. CROLY said he had more than one case of morbus coxæ, not in the early stage, under his observation, where the eversion was well marked, and he had often been puzzled to account for how that eversion occurred.

Mr. RICHARDSON—The point we want to decide is, what is the cause of the real shortening of the limb in the majority of cases?

Mr. TUFNELL said that in an operation he had seen where the head of the bone had been removed by excision it was found upon the dorsum of the ilium.

Mr. PORTER could verify what Mr. Tufnell had stated. His colleague, Mr. Collis, had excised the head of the femur in a case of morbus coxæ, and on that occasion it was dislocated on the dorsum of the ilium.

Mr. STAPLETON saw that case, and his impression of it was different.

Mr. PORTER said he saw the case before the operation, and as far as they could then judge, the head of the bone was lying on the dorsum of the ilium.

Mr. STAPLETON said he had sometimes found that the trochanter went upwards, and sometimes a remnant of the head of the bone was found lying in the acetabulum. Sometimes the amount of disease was not so great in the

acetabulum as might have been expected, while in other cases the acetabulum was greatly affected. He considered it was very rare to find a dislocation like that on the dorsum. His experience was, that it was an exception to have the foot turned in; it was more frequently turned outwards.

Dr. MACALISTER said that in most of the cases he had seen in the dissecting-room the acetabulum, was elongated upwards, and the neck of the femur was absorbed. In one case the head of the bone was lying in the acetabulum dissevered from the neck, and the neck was displaced on the dorsum of the ilium, and all the external signs in that case were precisely similar to dislocation on the dorsum, and in that case the ligamentum teres was quite perfect.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY OF LONDON.

TUESDAY, JAN. 23, 1866.

Dr. ALDERSON, F.R.S., President.

A CASE OF ACUTE UNCOMPLICATED MYOCARDITIS, IN WHICH THE DISEASE WAS DIAGNOSED DURING LIFE.

By C. B. RADCLIFFE, M.D., F.R.C.P.,

PHYSICIAN TO WESTMINSTER HOSPITAL AND TO THE NATIONAL HOSPITAL FOR PARALYSIS AND EPILEPSY.

THE case which forms the subject of this article is an example of a grave affection, of which there is little, if any, certain knowledge; acute uncomplicated myocarditis, or in other words acute inflammation of the muscular structure of the heart, without any inflammation of the endocardium or pericardium.

The patient was a fine, stout, strong, married man, middle-aged, a varnish maker by occupation. For six weeks he had had occasional attacks of sharp pain at the pit of the stomach, and shooting thence into the left arm—attacks evidently of the nature of angina pectoris. In other respects he thought himself well in health, and he was well enough to follow his daily work, and to get about with little or no discomfort up to the day before his death.

When seen for the first time (July 27th, 1865), the indications of the disorder evidently pointed to a very weak heart. The pulse was extremely feeble, and somewhat slow, but not irregular. The hands were cold and clammy—remarkably so. The first sound of the heart was absent. The cardiac impulse against the walls of the chest could not be felt. The second sound of the heart could be heard, but faintly only, and several times (in an examination extending over several minutes) it was distinctly reduplicated. There were no morbid sounds of any kind whatever. In the attempt to detect the cardiac impulse the patient winced more than once, and complained of feeling sore and tender at the part. There was no arcus senilis; the arteries were to all appearance free from atheromatous deposits, and, in short, the only indications of physical disorder were those which have been mentioned. The first attack of pain happened at a time of sudden and severe mental trouble. Previous to this the health had been in all respects excellent.

The patient was seen for the second time on the following day, and then he was dying. He was sitting awkwardly on the edge of a chair by the side of the bed, supported by his wife. On suggesting that his posture was a very uncomfortable one, he gasped out, "I must keep as I am—I dare not stir." He had been in this position for ten or twelve hours, literally without moving in the least." His face was pale and ghastly; large beads of sweat stood out on the forehead and went trickling down the face; his extremities, upper and lower, were clammy, and corpse-like as to paleness and coldness. The pulse at the wrist had failed altogether. His breathing was short, shallow, and gasping, and with it was a rattle, of which the significance could not be mistaken. His mind was clear and collected: he complained of sickness, and said he knew that he was dying.

The history given of this sudden change was this: that he got out of bed to pass urine in the middle of the night, after several hours' quiet sleep; and that while up for this purpose the pain at the pit of the stomach returned in an unusually severe form, with cold perspirations, and with a feeling of deadly faintness. For the next four hours this pain continued without intermission, even without alleviation, and then it ceased suddenly, and the condition as suddenly changed to that which has been described.

The post-mortem examination was made by Dr. Willis and Dr. Bazire twenty-four hours after death. In the cavity of the pericardium were nearly two ounces of serum, reddened by blood, but having no flakes of lymph in suspension. The pericardium itself presented no traces of inflammation, old or new; its visceral layer was intensely injected with ramifying capillaries filled with dark blood, but without ecchymoses, and elsewhere it was of the natural colour and character. The heart was dilated and flabby. The muscular structure of both ventricles, and in a lesser degree of both auricles also, was soft and friable, of a mulberry-juice colour, almost black in fact, contrasting in this respect, in a very marked manner, with the natural redness of the muscles of the chest-walls. It broke down readily under the finger like hepatized lung. As seen with the naked eye, it did not appear to be fatty; but there were considerable deposits of fat about the exterior of the heart. The endocardium and all the valves were quite healthy, and so also was the aorta. The left ventricle contained some loose, very dark clots of semi-coagulated blood; and in the right ventricle were some fibrinous, but not decolorized, clots adherent to the walls. Upon lifting up the heart by a portion of the right ventricle, the muscular structure broke down, and tore like wet paper by the weight of the heart itself. Unfortunately, no microscopic examination was practicable.

The grounds upon which the diagnosis was made were in the main these:—The history of the disease seemed to point to acute rather than to chronic disease—to begin suddenly in a way which suggested the idea of a "broken heart." There was no sufficient reason to suspect pericarditis or endocarditis, for there were none of the morbid sounds which mark the presence of these inflammations. So far seemed plain enough. It seemed, moreover, that the main symptoms were easily explainable on the supposition that the muscular structure of the heart had been attacked by inflammation. Inflammation of the muscular structure of the heart, as a matter of course, would weaken the muscular powers of the structure, and this weakening would account for that failure in the action of the heart which was the most prominent symptom. Moreover, the same weakening would carry along with it, if sufficient in degree, absence of the first cardiac sound, and absence likewise of the usual cardiac impulse. Nay, it seemed as if the symptoms present—sudden failure in the action of the heart, with loss of its first sound and of the impulse of the apex, with some tenderness on pressure in the intercostal spaces in the cardiac region, with some pain, but without the severe pain of pericarditis, without the morbid sounds of pericarditis or endocarditis, and without arcus senilis, atheromatous vessels, or other signs, good or bad, to point to common fatty heart—were all the symptoms and signs one had a right to expect in inflammation of the muscular structure of the heart. At any rate, it was on these grounds, be they sufficient or insufficient, that the diagnosis was made; and it was this diagnosis which led to the post-mortem examination, for if it had not been so, the body—such was the opposition of the friends—would have gone to the grave unexamined.

The PRESIDENT objected to the coinage of new words for cases of disease, and thought in the case just read carditis would have been a sufficiently distinct term.

Dr. RADCLIFFE referred to Dr. Stokes as his authority for the word he had used, "myocarditis."

The meeting then adjourned.

Reviews.

GUY'S HOSPITAL REPORTS.—Third Series, 1865.

THE present number fully maintains the character of this record of practical Medicine and Surgery, and contains much interesting matter. Some additional cases of Supra-renal Disease, with practical observations, are communicated by Dr. Wilks, also cases of enlarged spleen, with an outline of the history of some operations for its removal. The opinion of Dr. Spencer Wells, there alluded to respecting the feasibility of such a proceeding, has since been fully realized. A spleen weighing 6 lbs. 5 oz. having been recently removed by that enterprising surgeon, the patient surviving the operation six days.

The subject of Diseases of the Testicle in their clinical aspect is ably and clearly handled by Dr. Bryant, and the paper will amply repay the trouble of a careful perusal. We would, however, take exception to the departure from ancient landmarks in his definition of diffused hydrocele of the cord, which Dr. Bryant regards as contained within the funicular portion of the tunica vaginalis, the encysted variety occupying a portion only of that cavity. This distinction appears to us an unnecessary refinement, not required either by pathology or surgery, while the terms proposed by Pott and Scarpa *diffused hydrocele*, as applied to serous fluid, effused in the arcolar tissue of the cord, and *encysted*, as applied to that contained in the funicular tunica vaginalis, whether occupying a part or the entire of that tube, have been generally accepted by the Profession, alteration of which may give rise to misconception and confusion.

In Mr. Towne's paper on the Stereoscope will be found a philosophic investigation of the phenomena produced by this instrument, which has given rise to so much discussion and controversy; it may, however, be questioned how far such topics fall within the province of Hospital Reports.

A paper by Dr. Habershon on Diseases of the Skin, as they have presented themselves at Guy's, is replete with sound information on a class of cases which, of all others, require careful clinical observation for their study and elucidation.

The ventilation and warming of the new wards, Hunt's House, Guy's Hospital, is the subject of a communication by Dr. Steele, illustrated by means of carefully-executed diagrams, which will be read with interest by those concerned in the construction or alteration of hospital buildings, in accordance with the modern advance of sanitary science. It appears questionable whether the hygienic advantages of the plan adopted are proportionate to cost of construction.

A Course of Clinical Lectures by Mr. Hilton, characterized by great force and yet simplicity of style, contain many valuable suggestions from one who has always been esteemed as a rational, pains-taking, and scientific surgeon. They embrace observations on various fractures, injuries of the head, hernia, and cannot fail to instruct the reader. The description given of the nature and treatment of the injury known as "Colles' fracture" is not strictly that which has been given to us by Mr. Colles himself. That eminent surgeon neither used nor advocated the apparatus known as the "pistol splint," which was introduced by M. Blandin, and adopted as a substitute for the "attele cubitale," proposed by M. Dupuytren.

The puerile system of christening accidents and diseases is very justly condemned by Mr. Hilton, a system which is also too prevalent with superficial anatomists, and leads to no beneficial result.

Some useful notes on Poisoning by Fungi are contributed from the able pen of Professor Taylor.

A Case of Ruptured Popliteal Aneurism, by Mr. Poland,

with an illustration, and a number of cases of Acute Rheumatism, are quoted from the practice of Dr. Gull and Dr. Rees, in which the expectant treatment was adopted, apparently with as much success as any of the more heroic remedies which we occasionally hear extolled so highly, but which enjoy so ephemeral a reputation.

On the entire work we have to congratulate the Editor, Dr. Wilks, for the able manner in which it has been produced.

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 7, 1866.

THE NEW PARLIAMENT AND THE SICK POOR.

AFTER the excitement of the last twelve months or more on the subject of parochial mismanagement, there can be no doubt that the condition and the treatment of the poor will form prominent topics of discussion in the ensuing meeting of the Legislature. As Medical men, we have no desire to encroach on the province of matters foreign to our pursuits, and therefore we have no opinion to offer as to the treatment of the poor in general, or as to the hardships said to be endured by the vagrants and the "casuals." All these subjects must be discussed on the broad principles of ordinary law, justice, and humanity; but the Medical care of the sick poor, the adoption of hygienic measures in populous localities, and the enforcement of prophylactic rules—all these and other analogous duties now so strangely entrusted to and carried out by local Vestries and Boards of Guardians, are entirely within our jurisdiction, and it is our sacred duty to do all in our power to expose the evils of the present system, and earnestly to press on the Government and the Houses of Parliament the necessity of immediate amendment. Too long has the voice of scientific Medicine cried aloud in the wilderness, too long have sanitary reforms been shamefully and wilfully neglected, too long have the sick poor groaned under the infliction of workhouse tyranny; and it is now high time that the delinquents who have connived at, or openly defended, the existing abuses should be dismissed from the trust they have betrayed, and their places be filled by more competent and humane administrators.

We have not the slightest desire to press the case too hardly against the local authorities. We do not say that they are guilty of maliciously taking away the lives of their fellow-creatures, or of inflicting unnecessary sufferings upon the unfortunate sick inmates of the Workhouses; but we distinctly accuse them of wilfully neglecting, in very many instances, the adoption of sanitary measures, especially when their own interests are concerned in the movement, and we charge them with gross ignorance in nearly all matters connected with Medicine and those collateral subjects which bear

upon the public health. We charge them, moreover, with the most despicable meanness in nearly all their relations with the Medical Profession; with doing to our Medical brethren in a public capacity what they would have been ashamed to do, or legally prevented from doing, in a private one; and with making every other interest subservient to the pitiful object of saving some trumpery sum for the pockets of the ratepayers.

The class of persons from whom guardians and vestrymen are usually selected is that of parochial agitators and small shopkeepers, at least so far as the metropolitan districts are concerned, and although it is true that persons of intelligence and position in society are eligible and are sometimes chosen, yet the majority is composed of the materials we have described. When any of the better classes are elected into these heterogeneous assemblies, it is more than probable that after a very short probation of the vulgarity, violence, and ignorance of their colleagues, they refrain from attending the meetings, preferring very naturally the quiet of their own homes to the noisy discussions and coarse personalities of the Vestry Board. We once heard of a suburban vestry, who had a most momentous question presented to them, involving the health of many sick persons, and who, although comprising among their number several gentlemen of intelligence and respectability, delegated their functions entirely to three of the most ignorant and violent of the Board; one of the three being a publican and another a retail grocer. Such persons as these, having some little leisure, are the very persons who undertake the direction of sanitary measures, and if they can browbeat the doctor, call him offensive names, clip off his salary, or otherwise annoy him, so much the more sport is afforded to them, and so much the more triumph is expressed when they meet in conclave at their public-house clubs. The above is no fancy picture, and we appeal to many a Poor-law Medical Officer and Medical Officer of Health whether it is not represented in true colours.

The time has now arrived when the administration of sanitary measures should be entirely taken out of the hands of these local authorities. The time for doing so is opportune, because it happens that public indignation has been recently excited against the existing order of things, and an inquest on some neglected sick pauper, or a "night in a casual ward" passed by some literary amateur tramp, has produced more effect than could have been obtained from any efforts, however well meant, of any number of Poor-law Medical Officers even when backed by the Medical journals. Let the local authorities now be placed on their trial, and let the witnesses against them be protected from their malignity, and there can be no doubt of the verdict and the sentence. For the members of our own Profession, who have a long reckoning to make up with these unjust stewards, we ask no more than a clear stage and no favour. If Medical men have betrayed their trust or neglected their duties, let them by all means be censured

and punished, but if they have only done their duty to the sick poor and to the interests of humanity, then the State is bound to protect them, whether their conduct is pleasing or not to the Vestry or the Guardians.

TOPICS OF THE WEEK.

RAINEY BODIES AND CATTLE PLAGUE.

THE *Lancet* of last week contains a capital article from the pen of Dr. Cobbold on the so-called entozoa found in the muscles not only of rinderpest but healthy animals, and those of various kinds. It has yet to be disproved that these bodies are not very much more common in animals dying of the cattle plague. Microscopists affirm that in healthy muscle they are difficult to find, but that in diseased rinderpest muscle they are readily and at once detected. This is an important point to note. There still would seem to be a very considerable degree of uncertainty as to their exact nature, whether animal or vegetable. Dr. Cobbold rather shifts from the position he took, perhaps somewhat hastily, in the non-medical journals, and now takes up a mid-position, regarding them as animal protozoa, not vegetable, nor, on the other hand, true entozoa. The arguments adducible as contra-indicating a vegetable nature, are their peculiar seat and habitat, the fact that movements have been observed in similar, if not identical, structures by Lindemann, their complex structure and contents, the presence of a ciliated (?) coat, and the effect of iodine and liquor potassæ; yet the matter is one of great profundity. They would seem to be closely related to Gregarina, the contained cells presenting the characters of "pseudo-naviculæ." Whatever they may turn out to be, they are certainly very definite bodies, and most proper subjects for close and attentive study at the hands of our microscopic authorities.

THE WORKHOUSE QUESTION.

THE issues of the present excitement in regard to the condition of Workhouses, ought to be most beneficial to the whole community at large, and undoubtedly the present is essentially the right time to ventilate the many questions which, in so far especially as the Medical Profession is concerned, affect the well-being of our poorer brethren. All classes are on the tip-toe of attention, and for the moment seem fully inclined to enter heart and soul into any really reasonable plan of amelioration. Already in London the recent disclosures have stirred men into activity. Meetings of various kind have been held with the view of carrying out sanitary operations, instituting better attention to the wants of inmates of infirmaries, and the establishment of some scheme whereby the poor at large shall be better housed; and we are, we believe, correct in affirming that the various guardians of different parishes are meeting in conclave to devise some definite plan of reform. Now, this movement must be a national one, if it is to meet with any success, and we earnestly hope that no effort will be spared to agitate the question without a moment's delay. Unusual interest generally degenerates into a lukewarm sympathy.

We would especially counsel our Medical friends to rally round the champion of Poor-law Reform, Mr. Griffin; the cause in which they are interested must be discussed, and even those who hold no official appointment under

the most inefficient of all inefficient—the Poor-law Board—are bound in common honesty to give a helping hand to the cause. But there is another view of the matter, whilst we aid in any endeavour to secure to the poor man a better home in his old age, better Medical care, and for ourselves a fair return for honest services (and lately we have many notable examples of sacrifice of life at the shrine of duty from wholly unrequited hard wrought work), it must be recollected that Workhouses would furnish a great deal of knowledge in the cause of Medical education. One of the largest channels of clinical instruction to pupils might be hereby supplied; there are many eminent men in our profession who owe very much as regards the groundwork of their original elementary and even subsequent knowledge to the observations made in early days in workhouses. The Medical man has to bear the brunt of much trickery and red-tapeism, and it is essential to the full efficiency of workhouse management that he occupy a position more independent of caprice, and that he also have more power than is his lot at present.

VACCINATION AND THE CATTLE PLAGUE.

It is now definitely announced that vaccination offers no protection against the cattle plague, and that the arguments in favour of this treatment are fallacious. It will be recollected that we expressed our own doubts as to the close resemblance, if not identity, said to exist between the cattle plague and the small-pox, but still we desired that the experiments relating to this point should be fully and fairly conducted, and we hoped that our misgivings would turn out to be unfounded. But the experiments have now been so extensively carried out, and the results have been so unsuccessful, that even Dr. Murchison, who proposed the plan, has very gracefully acknowledged his mistake, and thus prevented any further waste of time in useless operations. The candour thus shown by a legitimate member of the Profession is favourably contrasted with the conduct of the homœopathic quacks, who, after utterly failing to cure or modify the cattle disease by the administration of their infinitesimal globules, make a ridiculous attempt to cover their failure by mendacious pretences that fair opportunities have not been afforded to them, whereas they had every facility granted to them consistent with honesty and truth. Still, we cannot help thinking that Dr. Murchison jumped too rapidly to his conclusions, and that one at least of our Medical contemporaries was in too great a hurry to announce to the public almost as a great and important discovery, a plan of treatment which, after all, rested on a very shadowy basis, and which is now shown to have no basis at all. In connexion with this subject, we received, a few days since, a communication from Broughton-in-Furness, in Lancashire, announcing to us that some Medical men in that district had prepared to appoint lay vaccinators of cattle at two pence a-head for each successful operation. As the vaccination of cattle is now at an end, it is unnecessary for us at present to allude further to this proposition, which however, we conceive to have been derogatory to the character of the Medical Profession.

SYPHILISATION.

At the recent meeting of the Harveian Society last Thursday, the subject of syphilisation was introduced by Mr. Victor de Méric, who is an avowed opponent of the prac-

tice, and who read a paper denouncing it in the strongest manner. He did not, however, adduce any facts in support of his own side of the question, but argued against the advocates of syphilisation on the ground of its immorality, its painfulness, and its tediousness. He showed that in France where it was introduced by Angias de Turenne it is now abandoned and denounced, and that the only places where it is still practised are Turin, under the auspices of Sperino, and Christiania, under the influence of Professor Boeck. Mr. de Méric admitted the great merit and perfect honesty of Dr. Boeck, and still he believed that the results did not justify the introduction of the new treatment. In reply to Mr. de Méric, Mr. J. R. Lane and Mr. Gaskoin (under whose superintendence the experiments on syphilisation at the Lock Hospital in London have lately been conducted) spoke in terms of modified approval of the practice, but stated that a sufficient period of time had not yet elapsed to enable them to form a definite judgment. The great point to be determined is whether syphilisation is really a more efficient method of curing the venereal disease than the administration of mercury or the expectant treatment, and also whether relapses are more or less frequent after syphilisation. Dr. Boeck's statistics affirm most positively that relapses are far less frequent under this treatment, but as the introduction of the practice in this country is still recent, it is only fair to wait a few months longer before either accepting or condemning the views advocated by the learned Professor of Christiania.

MANSLAUGHTER BY AN ASSISTANT.

An inquest was held last week at Stockton on the body of a man who had died of extravasation of urine from rupture of the bladder caused by overloading of the bladder. The man suffered from a close stricture, and the use of the catheter had been omitted by the assistant until too late, although the man begged repeatedly to be relieved. The jury returned a verdict:—"That the death of the deceased was caused through the want of competent skill and proper caution on the part of Mr. Simpson (the Assistant), and it is to be regretted that Dr. Richardson (the Medical Officer) did not see the deceased earlier."

We are sorry to say that the verdict appears to have been perfectly justified, and that the grossest neglect was evinced by the Assistant. Medical officers who employ unqualified persons to discharge their duties, cannot be held free of responsibility and blame, any more than a master can be acquitted for the fault of a negligent servant whom he has retained in service, knowing him to be so.

THE VENEREAL DISEASES COMMISSION.

WE understand that the Lords of the Admiralty have just received the report of the important Commission on the prevalence of venereal diseases in the Navy, and when it is laid before Parliament we believe that very energetic and stringent measures will be proposed for the abatement of the evil.

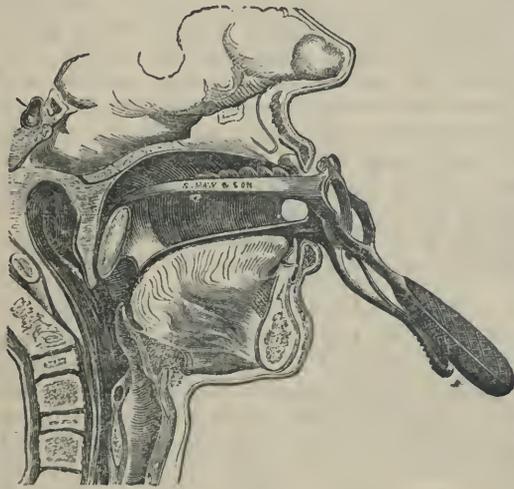

VENESECTION IN ITALY.—In giving an account of the death of the late Sir Charles Eastlake, President of the Royal Academy, the *Reader* says that, like the late Count Cavour, Sir Charles would seem to have fallen a victim to professional ignorance and prejudice in the adoption of a merciless course of blood-letting, which so completely prostrated him as to destroy the power of taking nourishment.

NEW INVENTIONS.

NEW BIVALVE SPECULUM FOR EXAMINING THE LARYNX,

MESSRS. MAW and SON of Aldersgate-street, London, have obtained licence from the patentee, Dr. LABORDETTE of Lisieux, for the manufacture of a new instrument for laryngoscopic purposes, which appears to be a valuable adjunct to those at present in use. It is a bivalve speculum, combined with a reflecting mirror.

The accompanying woodcut shows the manner of using the instrument, the posterior blade of which is curved to fit closely the back of the mouth, and descends more or less deeply into the pharynx; the inferior blade, which is shorter, penetrates as far as the base of the tongue, which it depresses by means of the lever spring fixed to the handle.

The instrument, introduced into the mouth, is pushed as far back as possible, the posterior blade being in the pharynx serves as a *point d'appui*. The tongue is then immediately depressed in the manner before described, by means of the lever spring acting upon the anterior blade, and exposes the orifice of the larynx reflected in the mirror.

In affections of a croupy nature, the diseased parts can be seen with ease, and caustic or the probang applied without any difficulty.

There are two sizes; one for children, and one for adults.

The price of the instrument is 3s.

Correspondence.

ON TRACHEOTOMY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I ask permission to insert in your excellent journal the following observations.—Yours faithfully,

T. G. GEOGHEGAN.

During the discussion at a late meeting of the Surgical Society on Mr. Tufnell's "Case of Tumour filling the entire Mouth and Fances,"* Dr. Croly observed that, as house-surgeon, he was about to tracheotomize a patient of mine, in which urgent difficulty of breathing existed, but that I having meanwhile arrived, performed the operation, and that the case was one in which it was impossible that the patient could live if the tube were intro-

duced, that it would have been perfectly useless, and would have choked him.* Dr. Croly must have spoken from imperfect recollection of the case. The operation performed was *laryngotomy*, and the double canula was introduced (as I find by reference to my notes, taken immediately afterwards) by Dr. Croly himself.

The case (the details and dissection of which are given at large in THE MEDICAL PRESS for November 21, 1860) was one of dilatation of the arch of the aorta, with an ingrafted aneurism. A fit of more than usually intense laryngeal dyspnoea† having seized the patient, the procedure just alluded to became at once imperative. I selected laryngotomy, both from the much greater rapidity with which it may be safely effected, and also in contemplation of the fact that an aneurism lay in dangerous proximity to the termination of the trachea, and that the scalpel or the canula might, under such circumstances, have become a source of danger, immediate or prospective, had tracheotomy been resorted to.‡

I quite concur in Mr. Fleming's judicious observation as to the greater eligibility of *laryngotomy* in cases such as that which formed the basis of discussion on the occasion alluded to. Its much greater safety and usual facility of execution, especially when time is of consequence, its comparative exemption from the more immediate dangers so often attendant upon tracheotomy (including in certain cases the possible admission of air into the venous system), and more remotely, as respects ease of expectoration, all concur in recommending it to the acceptance of the practical surgeon in various instances hitherto made the subject of tracheotomy. Within the last five years I have had thrice to perform laryngotomy at a moment's notice. In one case in the wards of the City of Dublin Hospital, a patient had attempted to bolt a mass of meat one ounce in weight. Owing

*The explanation about to be given should more properly have been offered at the meeting of the Society; as, however, the council (either of the Society or of the College) appears to consider an atmosphere containing, probably, some 10 per cent. of hot carbonic acid, &c., to be the indispensable vehicle for the conveyance of surgical information, those members who nobly prefer science to life and health, alone venture to attend. It must be matter of surprise that the City Officer of Health, who is also Professor of Hygiene to the College (apparently under the influence of an amiable lenity) appears never to have inspected the meeting-room of the Society in the discharge of his important functions.—"Quis custodiet custodes ipsos?"

†In the present case, the laryngeal spasm, which, I apprehend, was the main cause of the sudden and most urgent dyspnoea, was doubtless enhanced by an attack of bronchitis of the larger tubes, and of tracheitis acting on and producing spasm in certain muscles of an organ whose physiological equilibrium had been already disturbed by interrupted nervous influence, the result of pressure and irritation. "The left recurrent nerve (Report November 21, 1860) was adherent to and firmly imbedded in the parietes of the aneurism; it was atrophied, and its neurilemma injected. The left posterior crico-arytenoid muscle was much atrophied, its tawny colour strongly contrasting with that of the right; the other true laryngeal muscles of the same side were also atrophied, though to a much less degree. The left crico-arytenoid and all the laryngeal muscles of the right side were unchanged." Whilst, therefore, there existed paralysis of a muscular laryngeal group at the left side, a portion of the arytenoid (compound muscle) was doubtless in a state of spasm, the sympathetic result of bronchial and tracheal irritation. The singular barking or yelping cough (the true physiological significance and anatomico-pathological cause of which were, I believe, first pointed out by my friend Dr. Robert MacDonnell of this city) was very remarkable in the present instance.

‡Many years since I had under observation a young woman, who, having for a considerable time worn a tracheal tube for chronic obstructive disease of the larynx (but who was otherwise healthy, well nourished, and free from indications of pulmonary disease), perished suddenly from hæmorrhage through the wound, I conclude from ulceration of the innominata, produced by pressure of the end of the canula through an ulcerated trachea.

to closure of the mouth (as Mr. Stapleton practically remarks) it was impossible to use instruments for the removal of the foreign body; suffocation was imminent. The relief afforded by the operation was immediate and complete; the wound healed readily and speedily. It is worthy of remark, that on the admission of air the jaw at once relaxed, and the morsel was forced upwards by an anti-peristaltic action of the muscular coat of the pharynx.

The second instance was a remarkable one. The patient had been admitted for abscess beneath the upper part of the cervical fascia, the result of a preëxistent sub-acute glossitis. The abscess having been opened, the patient requested a drink of water previously to lying down. On attempting to swallow it, he was immediately seized with such violent and persistent laryngeal spasm that to save life I was obliged to open the crico-thyroid space forthwith. The venous hæmorrhage, which was abundant, ceased at once on the revival of breathing. The latter was immediate. The wound healed in a week.

The experience of many cases which have been operated on by myself and others forces upon me the conviction that death more frequently follows from failure of the process of expectoration (owing to the nature, size, and situation of the artificial opening) than from the effects of the operation in admitting insufficient air, and thus inducing bronchitis. The artificial opening (especially the usually larger one of tracheotomy), unlike that of the true glottis, is destitute of the power of accommodating itself to the conditions required for successful expectoration. It cannot contract at the moment of the expiratory effort, and hence the air current loses the requisite continuity and velocity.

Thus in the case of a young lady upon whom I performed tracheotomy for the extraction of a dog's tooth from the windpipe (and in which it was found necessary to enlarge the wound upwards through the median line of the cricoid cartilage), everything went well for more than a week, when she was suddenly asphyxiated (during my absence) by the resorption of a mass of viscid mucus into the bronchial bifurcation, and its impaction there after an unsuccessful attempt at expectoration. Peculiar conditions of the matter to be expectorated such as unusual solidity may also lead to a fatal issue, even where there is no artificial opening. An interesting case of this nature occurred many years ago under my observation, and formed the subject of an inquest in this city. A child died suddenly in convulsions shortly after taking a dose of pectoral mixture. A careful inspection of the cavities afforded no clue to the precise cause of death, and the inspector was about to terminate his researches, when, fortunately, it occurred to him to inspect the *larynx* and *trachea*. It was then found that a mass of semi-solid tubercular matter had become detached from a cavity in one of the lung summits. Cough failed to expel it, when, enveloped in a mass of mucus, it was drawn back into the bronchial bifurcation, thus causing asphyxial death. Had the windpipe not been examined, and had the cough mixture been found on analysis to contain a notable quantity of hydrocyanic acid, a very unfounded inference might have been the result. The uncouth and repulsive operation of oral suction alluded to in my case of laryngotomy, becomes occasionally necessary, owing to the difficulty of laying hands on a perfectly true-fitting syringe in perfect working order at the moment when an instant's delay may be fatal. Humanity and decorum here come into collision, and with Irish surgeons the former always triumphs. I was lately obliged to repeat this procedure in a case which I laryngotomized for diphtheria extending to the windpipe, in which the dyspnoea was most urgent and alarming, threatening immediate death; in this case I had the advantage of the assistance of the President of the College. The venous hæmorrhage was troublesome and blood had entered the larynx. In such a case, as late events in this city have shown, the proceeding of suction is not exempt from danger to the operator. I was amply rewarded for

the risk by the prolonged respiratory calm which succeeded to the operation, and to the removal of the blood which had trickled into the windpipe. After due explanation of the chances of success—so slight in such a case—the friends acceded to, indeed demanded, the operation.

It is a matter of practical note, that membranous casts* of the larger bronchial tubes in considerable quantity were both expectorated by the patient (a boy of some five years), and sucked out by my intelligent and assiduous assistant, Mr. Ohanessian Kevork, L.R.C.S.

The remarkable temporary effects of an artificial opening in cases of laryngeal diphtheria, I believe in croup, and in cases of scalding of the glottis (but not of the glottis only) by the vapour of boiling water, suggests the important inference that in these cases the respiratory distress is in a preponderating measure due to spasm of the laryngeal muscles rather than to swelling of the lining membrane of the larynx as a cause of diminished area of the glottis and its belongings. Hence the necessity of explicit warning of the friends where operation is contemplated, for, although the relief of spasm is immediate, the progress of the essential disease goes on unchecked. As, however, it would be evidently impossible to predicate with certainty in any given case that the operation *must* fail, or, in other words, to determine that the false membrane will pursue its usual route to the bronchial passages unimpeded, it appears to me that where absolute suffocation stares us in the face, and where the short duration of the disease (*quoad* the larynx) forbids the belief that the lungs have become hopelessly congested, and the smaller tubes consequently incumbered by mucous secretions or semi-serous exhalations (or by both), the surgeon is quite justified, nay, perhaps, called on, to afford his patient the chance of recovery, however remote. Should his efforts be crowned with success in but one out of a thousand cases, he will reap his reward. I am clearly of opinion that in such cases laryngotomy is the proper procedure.

Finally, even in children, foreign bodies of some volume, such as peas, &c., may be extracted by laryngotomy, the incision in the crico-thyroid space being rendered crucial, and the angles of the fibrous flap, if necessary, being removed by the scissors.

Parentetically, I may relate that I had proposed to myself some time since to laryngotomize a young man into whose larynx a fourpenny-piece had entered (and who failed for some days to expel it), as, preparatory to Sir Benjamin Brodie's plan of inversion of the body, whilst, however, the carpenter (true to the traditional procrastination of Irish workmen) was preparing the plank—Nature—that stern and wholesome monitress of intending operators—interposed and expelled the fourpenny-piece with a cough, the patient dismissing myself with a good-humoured sneer. The man when seized with cough had been stooping in the act of washing a carriage. If more space be demanded, I have advantageously employed division of the cricoid cartilage strictly in the median line a vertical slice also may, if necessary, be removed. This method will probably, answer, in children only. The division of the isthmus of the thyroid body, in the young subject at least, is exempt from danger, or, if thought fit, it may be slightly dissected from the cartilages of the upper tracheal rings, &c. and pushed downwards preparatory to division of the latter.

In laryngotomy, hæmorrhage is sometimes troublesome. It is usually venous, and ceases shortly after that the admission of air has dispelled venous congestion of the cervical system. Sometimes, however, the laryngeal branch of the superior thyroid artery which passes across the crico-thyroid membrane, bleeds smartly, but is readily checked by a slight collar of lint around the neck of the canula, or by scraping or torsion.

The difficulties of laryngotomy are, of course, greater in children and in females, both from the restlessness of the former, and in both from the absence of that saliency of the central crest of the thyroid cartilage which forms so satis-

* The specimens have been placed in the College Museum.

factory a landmark in the adult male. For comfortable laryngotomy it is of much moment to steady the larynx with the finger and thumb, to practise an ample external incision, and, lastly, to observe strictly the median line. If gum elastic are to be used, it would be well to provide them with a collar, the other end being truncated as usual, but having edge rounded off by the instrument maker, and the interior also varnished.

GANGLION OF THE WRIST.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR—In your number for November 15th, 1865, I have read a paper on "Ganglion of the Wrist," taken from the *Journal of Practical Medicine and Surgery*, in which I think an unnecessarily severe and dangerous treatment is recommended—viz., the excision of the enlarged bursa.

My treatment of this disease strictly corresponds with that recommended by Dr. Burnett in your paper of November 22nd, 1865, and I have never seen a case resist subcutaneous division of the sac expressive of its contents and subsequent application of pressure. Treated in this way ganglion of the wrist is a mild and easily cured affection, but it is often confounded with a very serious disease that requires very formidable treatment, and which is thus described by Baron Dupuytren under the head of "Hydatid Tumours of the Wrist," in the twentieth vol. of *Johnson's Journal*:—

"Encysted tumours, containing a number of small hydatidic bodies, of the size of pear-seeds, form occasionally on the palmar aspect of the wrist, under the aponeurosis, which exists at this part, and among the sheaths of the flexor tendons. Their nature is not unfrequently mistaken, and troublesome consequences have occurred from an injudicious treatment.

"Case 1.—A manservant, aged 30, having one of these tumours, was admitted into the hospital. It had existed for two years, and extended from about two inches above to the same distance below the wrist-joint. It was somewhat flattened on its surface, and felt like those large sub-pericranial wens, which used to be called *talpæ*, only that instead of being uniform it swelled out at the two ends, and was girt tight about the middle by the palmar ligament, thus resembling a double-pouched wallet. The skin at the part was not at all affected in colour. The hand could not be bent upon the forearm, and the movements of the fingers upon the hand were also impeded. Severe lancinating pains extended along the whole palmar extent of the forearm and deprived the patient of sleep. They were not, however, increased by pressure upon the tumour; but when this was done a sort of ecipitation was perceptible, just as when we pat a leather pouch, containing some very small leaden bullets; besides, the movement of the small bodies from one end to the other could be felt in this way, and either end might be made to swell out by compression upon the other. Experience having shown that any other mode of treatment but free incision of these tumours, or amputation of the forearm (as some have recommended in all cases), is not only useless, but possibly very dangerous, it was determined in the present instance to cut fairly through the sac, empty its contents, and induce a suppurative granulation from its interior. The operation was performed thus:—While an assistant pressed firmly upon the palmar ligament, so as to prevent the discharge of the fluid from the whole cyst, a transverse incision was made through the integuments and walls of one of its lobules, care being taken to avoid wounding the annular ligament of the wrist. An innumerable quantity of small, white, hard, oval or rounded bodies immediately escaped; the other lobule was then cut open and a similar discharge flowed out. The sac was thus entirely emptied. A small portion of its walls was pulled out of the wounds and snipped off with a scissors; it was found to be firm and fibrous, like wet parchment. A piece of lint was pushed into each orifice, so as to prevent them healing outwardly, and a light dressing laid over it. The strictest antiphlogistic treatment was enforced, the patient being bled, leeches, &c., and the arm kept suspended and constantly wet with a cooling wash.

"On the third day the wounds were examined; their edges were so puffy and swollen that the pieces of lint had been forced out and the openings were almost closed; the hand and forearm were red and inflamed, and so exquisitely

tender that the slightest motion caused great pain. The lips of the wound were gently separated, and pressure made so as to squeeze out any contained matter; the dossils of lint were then replaced and the member enveloped in emollient fomentations.

"Every unfavourable symptom gradually abated; granulations sprung up from the bottom, and on the fifteenth day the cure was assured.

"Great care was taken each day to empty the pouch of any pus which might be confined. Within the month the wounds were completely healed. The use of the local baths was ordered to be continued, for the purpose of relaxing the joint and facilitating its movements."

I was myself the subject of this disease for several years and was ultimately cured by the accidental rupture of the sac.

The history of my case is given in a number of *THE MEDICAL PRESS* for August 11th, 1841. In that article I offered the following explanation of the pathology of this affection:—

"Notwithstanding that Dupuytren's practice is judicious and successful, his pathology of these tumours is decidedly wrong, and may lead to an inert and temporising mode of treating these affections. Were the small bodies, hydatids, enjoying a distinct organisation and existence, as Dupuytren regards them, incision of the sac would be a proceeding fraught with danger. I have, however, examined them with the greatest attention, and am convinced that they are merely particles of lymph detached by the action of the tendons from the false membrane poured out during the process of inflammation on the synovial surface of the sheath; and further, that they form in joints where they are exposed to the influence of pressure, the nuclei of loose cartilages so frequently found in the knee and other articulations of the body. To this opinion I was led by having extracted from the knee of a man, on whom I lately operated for loose cartilages, a large number of these bodies, in every stage of formation, from small particles of plastic lymph to large and firm cartilages, formed by a cohesion of the small bodies, and rendered hard by the compression to which they were subjected."

In forming this opinion as to the nature of these bodies, I had the presumption to differ with Baron Dupuytren, who regarded them as organised and living beings; from Drumeric who considered them totally inorganic, and from Professors Pebrunti and Ragnetta, who pronounce them to be detached aneurisms or varices of the lymphatic vessels. There is another form of ganglion described by M. Chassaignac as sub-arterial tumour of the wrist, which sometimes leads to very serious error by being mistaken for radial aneurism. The best means of forming a correct diagnosis is by forcibly bending the hand upon the forearm, which by displacing the artery from its position over the cyst removes the intervention of a pulsating vessel and allows the tumour to be accurately examined. I have never seen this disease myself, but learn from the writings of Chassaignac that it is easily cured by iodine friction, but does not admit of treatment by incision, subcutaneous puncture or pressure, as in these cases the tumour communicates with the radio-carpal articulation.—I have the honour to be, your obedient servant,
Skibbereen, Dec. 22, 1865. DANIEL DONOVAN, M.D.

THE SALE OF VACCINE LYMPH.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As spurious vaccine lymph is being sent into circulation, and the result of such a fearfully wicked fraud is calculated to lead to much uneasiness to those who have used genuine vaccine lymph, and have either failed to produce any result or have not obtained the proper one, I trust you will allow me to remark that, for the last seven years, with but one exception, and that for a short time, I have been the only person who has advertised the sale of vaccine lymph in the *Lancet*, *Medical Times and Gazette*, *Medical Circular*, *Dublin Medical Press*, and other Medical publications. One gentlemen of undoubted respectability has also advertised lymph from the cow.

I beg to say that on no occasion has any but pure vaccine

lymph been collected or sent out by me, and I am sure my numerous correspondents, many of whom have been most successful in their operations lately on cattle, will kindly vouch for the truth of what I state. Surely those who state that spurious vaccine lymph is in circulation can also give the name and address of the persons from whom it was obtained, and thus set the general public on their guard against the imposition.

I am directed to ask you to allow this to appear, as I am receiving so many letters asking if I will guarantee the purity of the lymph supplied by me.—Your obedient servant,

W. FAULKNER, M.R.C.S.

40, Endell-street, W.C., and 12, Rosebury Villas, W.

POOR-LAW MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall feel obliged by your giving insertion to the annexed list of names of gentlemen who have forwarded their subscriptions towards the funds of the Association. I would willingly at once apply to the Poor-law Board and ask their consent to receive a deputation, but I fear the reply might be, "there is no proof now that any great body of the present Medical Officers are dissatisfied with their position."

If, however, 500 medical men should answer the appeal which Mr. Prowse has made to them, then I should feel justified in at once taking active measures either by a deputation to the Poor-law Board or by a Bill in Parliament.

List of subscriptions sent to Mr. Prowse of Amersham:—J. Blackshaw, Stockport, 5s.; W. A. Brice, Eton, 5s.; W. F. Brooks, Wye, 10s.; John Bowes, Blean, 10s. 6d.; W. Clark, Epsom, 10s. 6d.; J. Wilton, Ash, 10s. 6d.; R. O. Blythman, Rotherham, 10s.; W. C. Arnison, Hexham, 7s. 6d.; W. Montgomerly, Haltwhistle, 5s.;—Hewitson, Hexham, 7s. 6d.; J. Chapman, Brentford, £1; Brodie, Bellingham, &c., 5s.; B. E. 10s. To Mr. Griffin:—E. C. Buckoll, Radford, 5s.; F. Turtle, St. George-in-the-East, 5s.; J. Taylor, Banbury, 5s.; G. M. Ashworth, Oakham, 5s.; P. Wreken, Ashby de la Zouch, 5s.; T. O. Walker, Towcester, 5s.—Yours, &c.

RICHARD GRIFFIN.

STATE MEDICINE: AMENDMENT OF THE SANITARY LAWS.

MEETING OF THE METROPOLITAN COUNTIES BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

At a meeting of this Branch held on Friday, the 26th ult., Dr. Sieveking in the chair, Dr. Druitt, president of the Association of Medical Officers of Health, opened a discussion on Amendment in the Sanitary Laws. He said that more vigorous legislative powers were required for dealing with the everyday zymotic diseases, scarlet fever, typhus, diphtheria, small-pox, &c. He approved of the principle on which the existing machinery for carrying out the law was based—that of local self-government—but thought that the powers of vestries ought to be enlarged. If the powers of a vestryman were as great as those of a justice of the peace, the position would be as honourable and as much sought after. The vestries delegated their powers to the sanitary committees, which could not act on complaints without referring back to the vestry. If owners of property were recalcitrant the interference of the police magistrate must be sought. And the legal mind seemed to have no faith in sanitary measures, and sympathised usually with the defendant rather than the prosecutors in such cases. The law gave no power for removing or isolating infected persons in crowded tenements; and three weeks or a month was consumed by legal processes before any order to cleanse or disinfect premises could be carried out. It was very difficult to ascertain who was the owner of the house. The gist of the remedies which he proposed was, the consolidation of the Sanitary Acts. The local authorities should be invested with powers of removal and isolation in the cases referred

to, and of compelling the interment of the dead; and they should have greater summary powers.

Mr. Jabez Hogg, and Mr. Smith of Eltham, generally agreed with Dr. Druitt. Mr. Smith, however, stated that rural vestries could not safely be trusted with the proposed powers. What was really needed was a central authority—a State department to take cognizance of all matters relating to the public health. Dr. Webster of Dulwich, Dr. Chownc, and Mr. Lord of Hampstead, spoke in the same sense.

Dr. Sibson moved "That it be referred to the Council of the Branch to consider whether any and what steps may be taken for the purpose of securing a recognition of a Board of State Medicine as an integral part of the Legislature, and also what means may be adopted for obtaining a consolidation of the sanitary laws."

At the suggestion of Dr. A. P. Stewart, who seconded the resolution, it was amended, by remitting to the Council the task of considering also the measures to be taken for amending the sanitary laws.

Dr. Headlam Greenhow saw great difficulties in the way of the proposals mooted. It was idle to talk of giving to the vestries the powers proposed by Dr. Druitt. Such a proposal would never be sanctioned by the Legislature. However it might be in London, rural vestrymen were mostly ill-educated persons, who could not be trusted with such extensive powers. The consolidation of sanitary law was desirable, but could not be carried out to the extent apparently implied. The association must beware that it did not do mischief in asking again for a separate ministry of health, which had once existed, but had been swept away. The Vice-President of the Council was now charged with the subject of public health, and was responsible to Parliament: it was necessary to educate the public as to sanitary conditions before endeavouring to secure a more powerful position in the State for State Medicine.

After a few words from Dr. Druitt, the resolution was put and carried *nem. con.*

RETROSPECT OF THE JOURNALS.

THE *Lancet* hopes that during the present Session of Parliament efforts will be made to replace that time-honoured and useful institution, the *Dreadnought Floating Hospital*, by utilizing Greenwich Hospital, which has now become, as far as its inmates and objects are concerned, one of the things of the past. The floating hospital must be dreadfully inconvenient, and now, in these days of wholesale sanitary reform, its arrangements are sadly defective.

The formation of separate ophthalmic departments attached to general hospitals is urged. Some years ago, when the requirements of the Medical Department of the East India Company demanded special attendance on the wards of an ophthalmic hospital, several of the Dublin hospitals made arrangements for the purpose by devoting some beds to the care of some gentleman who had made ophthalmology a special study. The plan was found to work admirably.

The examinations of the Colleges of Surgeons and Colleges of Physicians are contrasted; that of the former is considered too limited.

A good deal of attention has been directed lately to the examinations of the London University, which by the majority are looked on as too severe, especially as regards the collateral branches, such as botany and zoology. Many good and sound men are prevented from taking the degree of M.B. through fear of the ordeal. We may expect some reform from the agitation going on at the other side of the Channel, but in Ireland any agitation seems to be fated to meet with increased opposition on the part of the governing bodies of the Colleges.

It seems probable that the Medical Officers of the Army will gain little by the Committee which has lately taken their grievances into consideration. The Indian Medical Ser-

vices is likely to get all the good men. Their *confrères* in the Navy have been more fortunate, and are likely to be placed in a better position.

In the discussion attending the publication of Dr. Waters's views on pneumonia, Dr. H. Kennedy of Dublin alludes to the fact that puerile respiration in the diseased lung during the earlier stage of the disease was first noticed by Dr. Stokes.

The failure of vaccination as a preventative against rinderpest has been complete.

We have an interesting lecture from Deputy-Inspector McClean of Netley, reviewing the different modes of treatment for cholera. He refers especially to Dr. Chapman's treatment by applying ice along the spine, but the idea is as yet young. Most assuredly it is to old Indian and China Medical Officers that we must look for the most perfect knowledge on the subject.

Mr. Hulme, one of the Medical Officers attached to the Manchester Royal Infirmary, has died from malignant typhus caught from the wards.

We find the fourth of Mr. Lane's valuable papers, "On the Surgery of the Rectum," in the *Lancet*. In this communication he takes up the treatment of rectocele—a bulging of the rectum into the vagina, and presenting externally through the vulva—generally due to lacerated perineum. We cannot do better than give his own words as to the operation, but in the original paper his description is supplemented by plates:—

"The principle is that of the quill suture, but in several of its details it will, I venture to think, be found an improvement on the methods in ordinary use. The patient being placed in the lithotomy position, a portion of skin and mucous membrane is dissected off on each side of the lower half of the vulva, so as to form a raw surface, which should be about an inch and a half in length on each side, the right and left portions being continuous with each other below across the median line. It should be an inch or more in depth antero-posteriorly at the lower part next the anus, but may diminish to about half an inch in depth towards its upper part. It is better first to mark the outline of this raw surface by incision with the scalpel, and then to dissect off the mucous membrane, the thinnest possible layer of which should be removed; but it should be taken away in one piece, and not in small fragments. I much prefer this plan to transfixing the part with the knife, and cutting a sort of flap from within outwards; in the latter way a larger amount of tissue is removed, which is objectionable, and vessels of larger size are likely to be wounded. By proceeding in the way above described I have never had occasion to place a ligature on a bleeding vessel, nor have I ever met with bleeding sufficient to cause inconvenience, either at the time of the operation or subsequently. Care should be taken that the denuded surface is not situated too far outwards upon the buttock or too far inwards towards the vagina, but just where the opposite sides would naturally and readily come in contact. The deep sutures, which are to hold the quills, are next to be inserted. For this purpose I am in the habit of using a strong needle of rectangular shape, set in a handle, and with an eye near the point. This should be entered unarmed, on the left side (the terms right and left refer to the patient, not to the operator), a full inch external to the anterior border of the cut surface; it should be passed deeply to take hold of as much tissue as possible, and brought out close to the posterior edge of the raw surface. It should then be thrust onwards through the tissues on the right side at a corresponding depth, and made to penetrate the skin at a point corresponding to that of its entry on the left. The eye near its point is now threaded with the wire suture, and the needle is withdrawn, carrying the suture with it. The needle should be bent at a right

angle about three inches and a half from the point, and should be slightly curved from the angle to the point. The sutures are then secured by being passed through the perforations in two ivory bars resembling the quill suture."

At University College Hospital a patient who had his leg amputated above the ankle died of pyæmia. There was sloughing and secondary hæmorrhage. The vessels were secured by acupressure. At the West London Hospital another patient who had his leg amputated in the same place died of gangrene. He was very old.

Dr. Day of Geelong gives an account of an easy method of obtaining ozone for sanitary purposes, by merely smearing the inside of a glass jar with a particular kind of old sulphuric ether.

From the *Medical Times and Gazette* we learn that there has been gross neglect on the part of some person or other as regards the sanitary arrangements affecting the removal of troops in India and China. We have reason to believe that the Medical Department from time to time protested against many of the orders, the compliance with which subsequent experience proved to be highly injurious. At any rate, there has been a great loss of life and detriment to the public service.

The assistant of a Poor-law Officer in the Stockton Union has been committed for trial on a charge of manslaughter. A patient died of urinary extravasation from stricture; no attempt was made to pass the catheter until the patient was *in extremis*.

M. Gounod's "Tobias" is to be performed for the first time for the benefit of University College Hospital. The celebrated "Messiah" of Handel was performed in Dublin for a similar purpose.

From abroad a Stornatoscope is noticed, by which the jaw can be rendered transparent and caries discovered.

Dr. Davies contributes some cases of acute rheumatism successfully treated by blistering.

Dr. H. Jones' lectures on the pathology of nervous diseases are still continued.

Dr. B. W. Richardson contributes a paper on a new method of producing local anæsthesia. Although the subject is not yet fully elaborated, yet it deserves consideration. It consists in directing a stream of pulverized sulphuric ether on the part. This produces intense cold; the temperature can be reduced to four degrees below zero. It is, however, hard to imagine how the reaction can occur without producing the same pain as follows the return of circulation in a frozen part.

In the *British Medical Journal* there is detailed a case where a fistulous opening in the loins communicated with the duodenum and kidney. A mulberry calculus existed in the latter, which was reduced to a mere cyst. The patient lived for a considerable length of time.

GLASGOW LYING-IN HOSPITAL.—The annual meeting of the subscribers to the Glasgow Lying-in Hospital was held in the Religious Institution Rooms, Robert Dalglish, Esq., M.P., in the chair. The report showed that the total number of cases treated in and out of the hospital, from 15th November, 1864, till the same period of 1865, was 650. The maternal deaths were 8. The children born alive in the hospital were 328; at their mother's houses, 298; still-born at full period, 18; premature, 17. In comparison with the report of last year, there has been an increase of 29 in the total number of women who have participated in the benefits which this excellent institution affords. Of that number six were indoor cases, and 23 received the necessary attendance at their own houses.

“LOOK UPON THIS PICTURE AND ON THIS.”

THE following remarks were lately made by the Judge sitting at the Old Bailey to a prisoner convicted of receiving money on false pretences, the pretence being that he was an attorney. The sum received was altogether only £47, and the prisoner obtained it by pretending that he would conduct some Chancery business for the prosecutor. We reprint the Judge's speech as showing the severe manner in which our law punishes a man for pretending to be an attorney, while it does not punish him at all for pretending to be a Physician or a Surgeon. The law evidently supposes that it is a criminal act for a man to presume to conduct a law suit without possessing a legal qualification, but that it is quite immaterial for an unqualified man to pretend to cure diseases and to defraud the public of their money under this pretence. The quack attorney, it will be seen, is utterly ruined, his wife and children are reduced to beggary, and he is (as a lenient sentence) imprisoned and kept to hard labour for four calendar months; the quack doctor, under precisely similar circumstances, would have been triumphantly acquitted, under the direction of the judge, and on his retirement from the dock would have been, in all probability, received with shouts of acclamation by the multitude.

“Mr. Commissioner Kerr, in passing sentence, said—You have been convicted of the offence of obtaining money by false pretences. The prosecutor wanted an attorney to prosecute his claim in the Court of Chancery to some particular property. You represented yourself to be one, or the representative of one, and to you he paid several sums of money. Although you were only prosecuted for obtaining £10 from him under false pretences, there can be no doubt that little or nothing was done by you either for the £10 or for the £37 odd besides which you previously received from him. There is, also, no doubt that the prosecutor was exceedingly wrong in placing his case in the hands of a non-professional man. The rule holds good here, as it holds good always, that it is a most unwise thing to do anything irregular. Instead of recollecting that rule, the prosecutor threw himself into your hands, and was dragged by you through a long course of expensive litigation; but the folly of the prosecutor in intrusting himself to your hands, instead of decreasing, rather increases your offence. You seem to have got upon the door of your office a brass plate on which is engraved the name of a solicitor. We are told that such a thing as this is being done extensively. I hope this case will have the effect of calling the attention of the Law Association to a practice whereby people live by establishing offices to which unwary clients are induced to go. These offices are no more and no less than so many traps. The name of a man is engraved upon a brass plate and placed upon a door. The man whose name is so engraved knows enough of law to be able to deceive the silly people who come to him. At the present time, and for some time past, the superior courts, and particularly the criminal courts of the metropolis, are infested with touters, or with a number of persons who profess to be touters. The courts of law have done all they could to put that kind of thing down, but hitherto all such attempts have been unavailing. But that is not the complaint here. This is a direct case of obtaining money by false pretences, and I have consulted with my colleague anxiously to see how you ought to be dealt with. It is only because you have hitherto held a respectable position, and that you might have thought you could do the prosecutor some service in getting him his property, that you will now be lightly dealt with. You were in difficulties, and you applied his money to your own use, thinking you would be able to give him value for it afterwards. You have a wife and large family, but that only increases your offence, for you not only offend against society by the crime, but you bring a slur and a stain on your wife and children, whom the court will protect in every possible way. At the same time I do not omit from consideration that the effect of this sentence is that you must lose your situation, and that you

will have a great struggle to begin the world again. I have a great desire therefore to modify your sentence. This, I believe, is the first case of the kind that has been prosecuted, and I hope, as I said before, that it will have a good effect in putting an end to a system which has been carried on to a large extent. It would not be fair, however, that you should be made the sufferer for the offences of others, but certainly something must be done to put down the prevalent system of persons practising as attorneys who are not attorneys. The sentence upon you is that you be imprisoned and kept to hard labour for four calendar months.”

THE SANITARY STATE OF SOUTHAMPTON.

DR. EDWIN HEARNE, who is at present residing at Aix-la-Chapelle for the improvement of his health, has written the following remarks in a letter to a Southampton paper:—

“Southampton possesses natural advantages which should ere this have made it a model town in a sanitary point of view. A mild, equable, genial atmosphere—well sheltered—a gravelly subsoil, which promotes rapid drying and a population greatly scattered, there being in the centre of the town about seventy acres of open laid out space, besides nearly 400 acres of public park within two miles. In my opinion the best parts of the town, at the present time, will bear comparison for salubrity with any town in the kingdom, and the people have only to be true to their own interests to make statistics demonstrate that as a whole no other place, with a population as large, can be shown to compare with it for healthfulness, independent of its other great advantages.

“What has been already done for the town will permit the remainder being accomplished at a comparatively trifling cost. Then why not have these necessary improvements been carried out sooner.

“I unhesitatingly answer because of the stolidity of the officials, and the incapacity of the Board of Health.

“Poor Cooper, on my remonstrating with him as often almost as we met, was in the habit of exclaiming, ‘What can I do, whilst only two or three in the Council know anything about, much less take any interest in, sanitary matters?’

“The baker, the butcher, the brewer, the clothier, the coal merchant, &c., may be considered as well acquainted with their individual occupations, but without doing them an injustice, what do nine-tenths of the forty gentlemen who constitute the Board of Health know, or what can they be expected to know, of sanitary laws?

“Acts have answered for them.

“Deaths have resulted in consequence of the accumulation of filth, dependent on defective sanitary arrangements, in different localities. The ordinary certificate has been refused by the medical attendant, and juries have declared the cause of death unnatural, and the consequence of culpable neglect. Even these unusual proceedings have had little effect in rousing the authorities from their torpor to a proper sense of their responsibility. A temporary cleansing enforced; but the permanent measures to prevent a recurrence of such calamities are still in abeyance.

“It is in such places that fevers constantly find the alimentary substances upon which they subsist, and worse pestilences, as often as the atmosphere becomes favourable to their development.

“Much has been said by a few non-medical writers about the name of the disease which prevailed in Southampton during the past autumn. It has been asked, and, in their ignorance, even dogmatically answered, whether it was *Asiatic, English, or spasmodic cholera*. Both English and Asiatic are *spasmodic*; English is rarely fatal, and wanting, in symptoms invariably present in Asiatic. Asiatic is fatal to a great extent, especially if neglected in its insidious and early stage. Both are produced by the same causes, but differ in degree, in proportion to the amount and quality of the poison imbibed.

“The question of quarantine has also been introduced. I have never entertained but one opinion, which is, that it is worse than useless. That it deranges commerce to an alarming extent, there can be no question, nor can it be shown that it has ever served a good purpose. Have plague, yellow fever, or cholera ever been arrested by quarantine regulations?—no. In the port of Southampton, small-pox, unquestionably a contagious disease, has been brought on shore

without hindrance, but not with impunity—whilst both cholera and yellow fever, unless I have been wrongly informed, have been subjected to what only exploded opinions could have tolerated. The arguments against the contagiousness of the above-named diseases are many, and, I think, indisputable. For the present I will adduce but one, which applies equally to both diseases. The most rigid quarantine has been found powerless in arresting the progress of cholera. It would be superfluous to give examples, since the instances where the strictest quarantine has been enforced for fourteen or twenty-one days, or even longer, without producing the desired effect, are very numerous—whilst the rapidity with which individuals became affected after arriving at a locality where cholera existed militates strongly against the opinion that the disease admits of a long period of incubation.

“The importance of the subject has induced me to enter thus fully into general sanitary matters, and my long connexion with, and intimate knowledge of, Southampton, into its sanitary condition and wants, in particular. Of the suburbs I may be tempted to write on some future occasion. Although favourably situated, they are undoubtedly becoming more and more insalubrious, and the inhabitants will have but a short time to wait before they are taught, as those of other places have been, that Nature’s laws cannot be set at defiance with impunity. Ignorance and selfishness combined may stop the way for a time, but the power of truth must prevail. I hope I have said enough to stimulate the authorities, urban and suburban, to vigorous and speedy action.”

SCIENTIFIC SOCIETIES.

ROYAL.—January 18.—General Sabine, President, in the chair.—The following papers were read:—“Sixth Memoir on Radiation and Absorption,” by Dr. Tyndall.—“On the Spectrum of Comet L, 1866,” by Mr. W. Huggins.

GEOGRAPHICAL.—January 22.—The Chairman announced that the Council had voted £200 in aid of the Leichhardt Search Expedition, which started from Melbourne in July last, and had been supported with large grants of money by the Legislatures of Queensland, Victoria, and South Australia. The expedition was under the command of Mr. D. McIntyre, a gentleman who, in a previous journey in search of new pastoral lands from Victoria to the Gulf of Carpentaria, had discovered traces of the lost explorer on the banks of the Flinders River. Mr. McIntyre’s search would be continued as long as the means, subscribed from time to time by public bodies and private persons, were forthcoming; and it could not fail in adding very greatly to our knowledge of the interior of the continent, even though it did not succeed in its main object of discovering further remains, or surviving members, of Leichhardt’s party.—“Description of the District of Cape York, Australia,” by Mr. J. Jardine. The author gave also a most interesting description of the aborigines, of which four distinct tribes inhabit the district.—“Explorations in the Neighbourhood of the River Glenelg, in North-Western Australia,” by Mr. J. Martin.

NUMISMATIC.—January 18.—Mr. Evans exhibited two Danish bracteate ornaments in gold of the Iron period, with loops for suspension. Similar specimens have been found in Saxon interments in Kent. Mr. Freudenthal exhibited a pattern for a decimal coinage. Mr. G. Brooks exhibited seven groats of the reign of Edward IV., Richard III., and Henry VII.; also two Burgundian coins found in excavations in the neighbourhood of the Edgeware-road. Mr. Boyne exhibited an unpublished medallion, being the second brass coin of the Lunetia family, surrounded with four concentric rings. Mr. Evans read a paper communicated by George Finlay, Esq., LL.D., entitled, “Thoughts about the Coinage of the Achaean League.”

STATISTICAL.—January 16.—Mr. T. A. Welton read a paper “On French Population Statistics.”

LINNEAN.—January 18.—Dr. St. Brody exhibited a number of rare plants, collected by himself in the neighbourhood of Gloucester, and some of which he believed to be new to Britain. The following papers were read:—“Flora of Banda,” by Mr. M. P. Edgeworth. “On some new British Polynoids,” by Mr. Ray Lankester.

ENTOMOLOGICAL.—January 22.—*Annual General Meeting.*—The President announced that the Council had awarded a prize of the value of five guineas for an essay “On Ailan-

thiculture,” the author of which proved to be Alexander Wallace, M.D., of Colchester. This valuable memoir, in which the writer, from personal experience, demonstrates the practicability of the cultivation in this country of the Ailanthus silk-worm (*Bombyx Cynthis*), will shortly be published by the Society. The President, before vacating the chair, read an address “On the Progress of Entomology during the Past Year.”

MATHEMATICAL.—January 15.—*General Meeting.*—Prof. De Morgan, President, in the chair. An abstract of the proceedings during the past year having been read, the President made a few remarks upon the satisfactory state of the Society. He called attention to the novelty and importance of many of the papers, and remarked that this was the only Society in England where such papers could be received.

CHEMICAL.—January 18.—Dr. Gladstone read a paper “On Pyrophosphotriamic Acid and its Salts,” of which some are remarkable for their complex and anomalous constitution. Professor Wanklyn gave a preliminary account of his researches “On the Action of Carbonic Oxide upon Sodium Ethyl,” which furnishes a body named diethylated formic aldehyde, with extrusion of the metal sodium.

SOCIETY OF ARTS.—January 17.—The paper read was, “On Automatic Telegraphy,” by Mr. A. Bain.

THE OBSTETRICAL SOCIETY.—The following papers are to be read at the next Obstetric Society meeting, Wednesday, February 7th, eight p.m.:—Dr. Snow Beck, “On Enlargement of Uterus,” &c.; Dr. Sanson, “On the Anæsthetic Properties of Bichloride of Carbon,” and other papers.

MEETINGS FOR THE ENSUING WEEK.

- WED.** Society of Arts, 8.—“Dwellings for the People,” Mr. Biggs.
THURS. Royal Institution, 3.—“Heat,” Prof. Tyndall.
 — Chemical, 8.—“Utilization of Town Sewage,” Dr. Gilbert.
 — Linnean, 8.—“Anatomy of Echinus,” Mr. St. G. Mivart.
 — Anthropological, 8.—“The Negro,” Captain Pim.
 — Antiquaries, 8½.—“Murrain of 14th Century,” Mr. Harrod.
 — Royal, 8½.
FRI. Royal Institution, 8.—“Influence of Arabic Philosophy on Mediæval Europe,” Earl Stanhope.
 — Philological, 1.—“French Homonymy,” Prof. Cassal.
SAT. Royal Institution, 3.—“Art Education: how Works of Art should be viewed,” Prof. Westmacott.

MEDICAL OBITUARY.

DEATH OF DR. TAGGART, ANTRIM.—In our obituary of to-day will be found a notice of the decease of this most estimable gentleman from typhus fever, caught in the discharge of professional duty. About twelve days ago the first symptoms of the treacherous malady were observed; and, despite the skill and unremitting attention of Drs. Seaton Read (Belfast), and Spearing (Antrim), who were in attendance, their patient succumbed ere the crisis was reached. As a physician, Dr. Taggart stood high with his medical brethren, who always respected his sound judgment, patience, and honourable courtesy; and a wide circle of sorrowing friends throughout the community testifies to the esteem in which he was held by the general public. By marked liberality of sentiment, a candid and generous disposition, and a happy Christian consistency of life, the lamented gentleman had endeared himself to multitudes who never sought his professional skill. He has been cut off in the prime of life, and leaves a young widow and several children to mourn his loss.—*Northern Whig.*

This is the second Doctor within three years that is reported to have died from typhus in Antrim town. It is to be hoped that in the course of time the services of Medical men will be fairly appreciated, and that when they fall victims to disease, acquired in the performance of their sacred duties to the public, that the parishes that have benefited by their services will feel it to be *their duty* to give small *pensions* to the sorrowing widows, who are seldom provided for.

We learn also that Mr. Hume, Physician Assistant at the Manchester Royal Infirmary, has fallen a victim to an attack of virulent typhus, contracted in the discharge of his duties. The public should set a higher estimate than they do on the daily risk incurred by self-sacrificing Medical Officers in the discharge of their duties.

SIR JOHN MCGREGOR, M.D., K.C.B.

SIR JOHN MCGREGOR was the second son of the late Mr. Duncan Macgregor of Culross, county Perth, N.B., by Mary, daughter of Mr. John McDermott of Perth. He was born October 20, 1791, and educated at the University of Edinburgh. Entered the medical department of the army 1809; served in the expedition to Walcheren 1809, and was present at the taking of that island and the forts of Terbeer and Ramakins; Present at the siege of Flushing, and served with part of the army in South Beveland, General the Earl of Chatham commanding; served in the Peninsula under his Grace the Duke of Wellington from 1811 to 1813, and was present at the siege of Badajos, and in all the cavalry actions against the French in Lord Hill's advance to Merida, and the retreat from Burgos, as well as in various other operations of the second division of the army in Spain and Portugal, was appointed surgeon to His Royal Highness the Duke of Sussex, 1st of February 1819; served in the Presidencies of Madras and Bombay, twice in Bengal and the island of Ceylon; was present at the capture of Fort M'aura and the surrender of the town of Kurrachee in Lower Scinde; was senior medical officer of the army sent to the relief of the forces employed against the Fort of Kujjuck, Upper Scinde, 21st, 22nd, and 23rd of February, 1841; present during the investment of Kandahar, end of 1841, beginning of 1842; senior medical officer of the force sent under Brigadier W. Mercer for the relief of Kelat-el-Ghazie, 1st of May to the 7th of June, 1842; present during the second Afghanistan campaign, 1842, and with an army on its return to the British provinces, through the Khoord, Cabool, and Khyber Passes, 1st of August to the 23rd of December, 1842, and was present at the following actions fought during the foregoing period—the battle of Kallee Shuck, 12th of January, 1842; present at the actions of Runga Duck, Pangwaria, and Zilla-Ostracy; 7th, 8th, 9th, and 10th of March, 1842; present at the battle of Baba Walla, 25th of March, 1842; battle of Gowine, 30th of August, 1842; at the capture of Ghuznee and the storming of the heights of Belleol, 5th and 6th of September; present at the affairs of Bene Bedam and Mydam 14th and 15th of September; present during the attack on the rear guard from Soorkab to Gundamuck (Khoord Cabool Pass), 10th of October; affair with the rear guard from Lundekama to Ali Musjid (Khyber Pass) 4th and 5th of November, 1842; was principal medical officer with the Kundahar field force during the whole of these operations under the command of Major-General Sir W. Nott; present and acted as principal medical officer of Queen's troops at the battle of Maharajpore, in the dominions of Seindia, 29th of December, 1843, General Lord Viscount Gough commanding; served a second time in the island of Ceylon, and was senior medical officer in the Kandian provinces during the rebellion in 1848. Was three years principal medical officer in Hongkong, China, 1850 to 1853; three years as deputy-inspector-general and principal medical officer at Madras, 1853 to 1856; one year and two months as inspector-general in Bengal, and travelled during the latter period in the performance of his duties 4462 miles. Served in the North-West Provinces of India during the mutiny of the Native Bengal army. Was present at the siege of Delhi, and the storming and capture of the city on the 14th of September, 1857. Sent as principal medical officer with the army proceeding to Lucknow under the command of Sir C. Campbell, and was present at the capture of the city in March, 1858. Recommended for promotion by Lieutenant Colonel Hibbert, commanding the 49th, and Major-General Sir W. Nott, for services performed as chief medical officer of the Kandahar field force in Beloochistan, Scinde, and Afghanistan. Recommended for promotion by his Excellency the Commander-in-Chief in India for services performed at the battle of Maharajpore, but was the only officer at the head of a department in Sir W. Nott's army not promoted on its return to India. As before stated, he entered the medical department, as hospital assistant June 27, 1809; became assistant-surgeon February 15, 1810; regimental surgeon April 30, 1822; staff surgeon July 7, 1846; deputy inspector-general, 1853; inspector-general, 1856. Sir John was made an honorary physician to Her Majesty in August, 1859, and was, in recognition of his eminent professional services, created a Knight Commander of the Bath the same year. In August, 1863, he assumed the name of McGregor instead of his patronymic, the family being descended from the McGregors of Rora, the name having been changed after the rebellion in Scotland in 1745. He died at Corstorphine-lodge, Ryde, Isle of Wight, on the 13th of January, 1856, at the age of 74. He was buried at the cemetery in that place.

Medical News.

ERYTHEMA NODOSUM during January has been prevalent in and about Belfast. It has been confined chiefly to children, with, however, notable exceptions occasionally complicated with pneumonia, and in some cases with fever of a remittent character becoming intermittent. Nocturnal attacks of severe colic frequently attend the disease.

The libraries of our provincial hospitals and the

libraries of several foreign universities have received from the Council of the Royal College of Surgeons of England upwards of 570 volumes of the illustrated Catalogue of the Museum of the College.

DR. FORBES WINSLOW.—The profession and the public in general will be glad to learn that this distinguished psychologist, who has been for some time past suffering from severe illness, caused by a fall from his horse, has sufficiently recovered from the effects of the accident to resume his professional duties. We also learn that Dr. Winslow is preparing for publication a new edition of his work on "Obscure Diseases of the Brain and Mind."

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners on the 25th ult. :—

Budd, Herbert Goldingham, Worcester.
Bahot, William Ifill, M.D., Tobago, West Indies.
Bushell, Stephen Wootton, Brixton.
Diver, Thomas, M.D., London.
Gorden, Henry Pelham, Queensland.
Hussey, John Fraser, Salisbury.
La Mert, Israel John, Albemarle-street,

It is stated that of the fifty-six candidates who presented themselves for examination on the 23rd, 24th, and 25th, ult., only eight were referred back to their studies for six months.

ROYAL COLLEGE OF SURGEONS OF IRELAND.—The following Gentlemen passed on February 3rd :—

Fellowship.
Mr. Edward Alfred B'rech.

NAVAL SURGEONS.—At a meeting of the Court of Examiners of the Royal College of Surgeons of England on the 25th ult. the following Assistant-Surgeons in the Royal Navy passed their examinations for full Surgeons in that department of the public service :—

Colquhoun, Archibald Grant, of the Royal Marine Infirmary, Woolwich; Diploma of membership of the College dated July 30, 1861.
McMorris, Robert James (half pay); member May 16, 1859.
Yarde, William, M.D., of H.M.S. Industry, Woolwich Dockyard; member July 3, 1857.
Curtis, George, of Haslar Hospital; Licentiate of the Royal College of Surgeons, Ireland, May 20, 1861.

APOTHECARIES' HALL.—The following gentleman passed his examination in the Science and Practice of Medicine, and received a certificate to practise on the 25th ult. :—

Pearson, Henry, Plymouth-grove, Manchester.

The following gentlemen also on the same day passed their first examination :—

Hall, Richard Strange, Manchester Hospital.
Thurston, William French, Guy's Hospital.

Of the thirty-two candidates who presented themselves for the Preliminary Examination in Arts on the 26th and 27th ult. the following passed, and received certificates of proficiency in general Education :—

William Atter, Edward E. A. Batchelor, J. H. Clark, G. K. Elphinstone, Wm. E. Fulford, Henry B. Harrison, Chas. Hamor Hill, Thos. Wood Hill, Wm. Hodgson, W. H. Johnson, John C. Keighley, Henry Medd, J. W. Moss, Alfred Blake Norman, Windham Randall, B. Steward Ringer, Wm. Sheard, H. H. Sprutt, Thos. Unicum, Saml. Walker, Francis Warner, F. W. Willmore.

CAMBRIDGE UNIVERSITY.—The following have obtained the Professor's Certificate in Comparative Anatomy :—

Blyth, L. G., Corpus College.
Fitzgerald, C. T., St. John's College.
Tucker, J. K., Magdalen College.

AROMA OF COFFEE.—The berries of coffee, once roasted, lose every hour somewhat of their aroma, in consequence of the influence of the oxygen of the air, which, owing to the porosity of the roasted berries, can easily penetrate. This pernicious change may best be avoided by strewing over the berries, when the roasting is completed, and while the vessel in which it has been done is still hot, some powdered white or brown sugar (half-an-ounce to one pound of coffee is sufficient). The sugar melts immediately, and by well shaking or turning the roaster quickly, it spreads over all the berries, and gives each one a fine glaze, impervious to the atmosphere. They have then a shining appearance, as

though covered with a varnish, and they in consequence lose their smell entirely, which, however, returns in a high degree as soon as they are ground. After this operation, they are to be shaken out rapidly from the roaster and spread on a cold plate of iron, so that they may cool as soon as possible. If the hot berries are allowed to remain heaped together, they begin to sweat, and when the quantity is large the heating process, by the influence of air, increases to such a degree that at last they take fire spontaneously. The roasted and glazed berries should be kept in a dry place, because the covering of sugar attracts moisture.—*Baron Liebig* in "Popular Science Review."

COMMITTEE ON CONTAGIOUS DISEASES.—The Committee on this important subject has just sent in a report of its lengthened sitting of upwards of a year to the Lords of the Admiralty, and it is understood that some very stringent measures are proposed with a view to diminish the great and predominant evil which has proved so great an injury to the men of the two services.

WILLIAM CARTE, Esq., Physician and Surgeon to the Royal Hospital, Kilmainham, has been appointed to the Commission of the Peace for the County and City of Dublin.

NOTICES TO CORRESPONDENTS.

Mr. Faulkner's letter, which arrived too late for our last week's number, is inserted.

Dr. Murray.—The notice is inserted.

Mr. Griffin's letter is received.

The Harveian Society.—The report is received.

A. B., Broughton-in-Furness, Lancashire.—The subject is noticed in another part of our present number.

Lector.—In cases of sudden and acute vascular protrusion of the eyeball, the ligature of the common carotid artery has been often attended with success. Mr. Nunceley of Leeds believes that this affection is sometimes due to pressure exerted on the ophthalmic vessels in the cavernous sinus.

A Student.—Greek is not compulsory at the Preliminary Examination mentioned by our Correspondent.

Quero.—The physician in question is not at present in England. The report alluded to we believe to be unfounded.

Dr. J.—The newspaper has reached us, but we are unable to find the paragraph alluded to.

BIRTHS and DEATHS Registered and METEOROLOGY during the Week ending Saturday, January 27, 1866, in the following large Towns:—

BIRTHS.

On the 25th of Nov., at Tien-Tsin, China, the wife of Thomas A. Ainslie, M.D., of a daughter.

On the 10th ult., the wife of R. Istance, M.R.C.S.E., of Risca, of a daughter.

On the 13th ult., at Milnthorpe, Westmoreland, the wife of Hanson Evison, M.R.C.S.E., of a son.

On the 21st ult., at Hillside Cottage, Chirnside, Berwickshire, the wife of C. Stuart, M.D., of a son.

On the 23rd ult., at South Penge-road, Penge, the wife of E. Diver, M.D., of a daughter.

On the 23rd ult., at Woodstock, Oxon, the wife of Dr. Frederic Taylor, of a son.

On the 24th ult., at Reigate, the wife of H. Harris, M.R.C.S.E., of a son.

On the 24th ult., at St Helens, Lancashire, the wife of E. P. Twyford, M.D., of a daughter.

On the 25th ult., at Springfield, near Tooting, the wife of J.S. Biggs, M.D., of a son.

On the 25th ult., at Manchester-square, the wife of W. H. Fuller, M.D., of a daughter.

On the 25th ult., at the Priory, Wrexham, the wife of T. Eyton Jones, M.R.C.S.E., of a daughter.

MARRIAGES.

On the 24th ult., at Hampstead, Charles Hammond, L.R.C.P.L., to Amelia, daughter of T. Hawkins, Esq., of Gloucester House, Hampstead.

On the 25th ult., at Edlington, Rowland Hills, M.R.C.S.E., of Conisbro, Doncaster, to Miss Harriet, daughter of Edward Parker, Esq., of Bailley, near Doncaster.

On the 24th ult., at Aberdeen, G. Park, M.D., Army Medical Staff, to Christian, daughter of the late P. Williamson, Esq.

DEATHS.

On the 7th ult., at Acre House, Brixton, Mary Ann, wife of Benj. Evans, F.R.C.S.E., aged 50.

On the 18th ult., at Monkwearmouth, Andrew Monro, Surgeon, formerly of Ovingham, Northumberland, aged 77.

On the 19th ult., Peter Macintyre, M.D., of Canning-street, Liverpool, aged 68.

On the 23rd ult., at Hurst, near Mauchester, after a short illness, Adriana Margaret, daughter of William and Adriana Harris, of Worthing, Sussex, aged 17.

On the 24th ult., at Wymondham, Norfolk, Thos. Edward Tawell Colman, Surgeon aged 68.

On the 24th ult., W. G. Walker, M.R.C.S.E., of Oxford, formerly of Brill, Bucks.

On the 25th, ult., R. J. Griffith, Surgeon, of Adelaide-road, South Hampstead, formerly Surgeon R.N., aged 79.

On the 25th ult., R. G. Mackee, M.R.C.S.E., of Hushwaite, Yorkshire, aged 20.

On the 28th ult., W. H. Evans, M.R.C.S.E., of St. Albans, aged 53.

On the 16th ult., James Leitch, L.R.C.S.Ed., Surgeon R.N., of Crieff, Perthshire, aged 84.

On the 28th ult., R. Laycock, L.R.C.P.L., of Bramley, Leeds, Yorkshire.

On the 10th inst., at Chatham, J. B. Jardine L.R.C.S.Ed., Staff Assistant-Surgeon Army, aged 28.

Original Communications.

SOME REMARKS ON THE VALUE OF LARYNGOSCOPY.

Being a Reply to Dr. EBEN. WATSON,

By MORELL MACKENZIE, M.D. Lond., M.R.C.P.,
PHYSICIAN TO THE HOSPITAL FOR DISEASES OF THE THROAT.

A PAPER of mine, which was published in the second number of THE LONDON MEDICAL PRESS AND CIRCULAR, has called forth an article from Dr. Ebenezer Watson, which necessitates my again craving the attention of the readers of this journal.

Dr. Eben. Watson's charges are so numerous that, lest any should be omitted, I must beg to answer them categorically.

1. Dr. Watson, complains in a general way of my having misrepresented him, and of my having "attacked" in this journal papers which he published in the *Lancet* in June and July, 1865.* He considers that this was "not the proper course, because the readers of the two periodicals may be different," &c. Here I feel called upon to remark that the "attack" was commenced by Dr. Eben. Watson (in the *Lancet* of July 1st, 1865), and that I am only acting on the defensive. As regards "the proper course" to have taken, I may observe that whilst I did not think Dr. Ebenezer Watson's "Revelations" of laryngoscopy were sufficiently important to call forth a letter from me at the moment they were disclosed, I can see nothing improper in incidentally referring to them when writing at a later period on a subject connected with laryngoscopy. I had the less hesitation in referring to the subject in THE MEDICAL PRESS AND CIRCULAR, as Dr. George Johnson, writing on laryngoscopy in the *Lancet* of August 26th, 1865, had already called the attention of the readers of that journal to the antiquated notions of Dr. Eben. Watson. Dr. Johnson's remarks on the "Revelations" did not, however, evoke any reply from Dr. Eben. Watson. As regards the justice of the general charge of misrepresentation, those who read this communication will form their opinion.

2. Dr. Eben. Watson, whilst modestly placing himself side by side with Cheyne, Porter, Ryland, Trousseau, and Green, considers that I have depreciated the works of my predecessors. By referring to my paper, however, he will see that I expressly observed, in speaking of the first three of those eminent practitioners, that they "would doubtless have been only too glad to welcome the new mode of examination," had they not unfortunately "long passed away." Trousseau and Green, happily, are still among us, and have not, as far as I am aware, opposed the laryngoscope, as invented by Czermak.

Dr. Eben. Watson, though associating his name with these practitioners, stands in a very different category.

3. Dr. Eben. Watson now says, "My experience in its application (that of laryngoscopy) to diagnosis is now considerable, and my faith in its results is very great." On both these points I congratulate Dr. Eben. Watson especially as regards the latter, as it shows such a manifest conversion since last July.

4. Dr. Eben. Watson next accused me specifically of misrepresentation. In my paper I said that he implied that laryngoscopy was almost superfluous in diagnosis.

and certainly useless in practice. To this sentence Dr. Watson takes exception, and says that his words were "that the application of the laryngoscope to the investigation of the diseases of the larynx is a very welcome addition to our means of diagnosis. It gives another and entirely new source of evidence to judge from, and it is therefore fitted to make our opinions more correct and our treatment more definite than heretofore. Dr. Eben. Watson seems to forget that he also remarks that "in regard to the ordinary application of solutions to that organ (the larynx), he had found the laryngoscope at once useless and unnecessary." Again he says, "In children it is quite impossible to make a good laryngoscopic examination." In respect to this statement I may observe, that two children, aged four and six, were brought by me before the Pathological Society during the progress of the cure or evulsion of warty growths with the aid of the laryngoscope and my laryngeal forceps. These children were examined with the laryngoscope by many of the Fellows present (see Transactions of the Pathological Society, vol. xvi., page 38). Again, whilst admitting that "cases of special difficulty may arise in which some degree of uncertainty may be removed or diminished by laryngoscopy, in the great majority of cases he can, with sufficient certainty for all practical purposes, ascertain the nature of the affection without having recourse to the new diagnostic at all." So much for Dr. Eben. Watson's former faith in laryngoscopy for diagnosis. It would be easy to give numerous other instances of Dr. Eben. Watson's endeavour to "damn with faint praise." The whole tone of his articles showed that he was incapable of appreciating either the value of laryngoscopy or the labours of laryngoscopists. Thus, in speaking of laryngeal growths, which have been so repeatedly observed by eminent physicians, he observes, "I cannot repress the wish had these strange visions been given to them a little less frequently, for it seems odd that such cases do not occur to others," &c. &c. Though it is scarcely likely that laryngoscopists will control their observations so as to suit the "Revelations" of Dr. Ebenezer Watson, the readers of this journal will be somewhat surprised that these remarks came from a physician who calls upon others to be "fairer and more charitable to his fellow-labourers in the field of applied science."

5. Dr. Eben. Watson remarks in the "Revelations":—"Dr. Mackenzie mentions his having in several cases removed small, and apparently from the sketches given in the work already referred to, hair-like warts from the glottis by means of his forceps, guided by the laryngoscope. Now, this is rather a wonderful feat in surgery, for in such cases the operator has to manage the forceps with his right hand whilst he holds the mirror with his left," &c. &c. I can assure Dr. Eben. Watson that a large number of practitioners who have attended my demonstrations have learnt to perform the "wonderful feat" of introducing a brush into the larynx in this way after a few trials. The use of forceps and other instruments is, of course, more difficult, but, as Dr. Johnson said, "I should have thought that the number of well authenticated cases in which morbid growths in the larynx have been discovered and removed by the aid of the laryngoscope would suffice to convince even the most sceptical that growths in this situation are not uncommon, and that their removal by the aid of the mirror presents no insuperable difficulty. As regards the warts figured in my book being "hair-like," I may observe that anything more unlike "hairs" could scarcely be drawn. The excellence of the illustrations (for which I am indebted to Mr. Orrin Smith) has called forth the unanimous approbation of the medical press, and if these warty growths appear "hair-like" to Dr. Watson, I am not surprised that, in attempting to apply remedies to the larynx, he should trust rather to the sense of touch than that of sight.

6. As regards Dr. Eben. Watson's "not perceiving the advantages of my little inventions," I can only say how proud I feel that even one of my instruments should not

* These papers were entitled "Laryngoscopy and its Revelations."

meet with his unqualified condemnation. He formerly said that "he thought my laryngeal galvanizer was likely to be innocent but very inefficient."

Such an expression appearing in the "Revelations" of Dr. Eben. Watson amounted, as I foolishly imagined, to a "description," but I am now informed that, although thus "revealing" in the pages of the *Lancet*, Dr. Eben. Watson had actually never seen the instrument! Now, however, that he has seen it, he considers that it performs the office it was intended for. Though he is kind enough to promise a report on two cases he is at present treating with my instrument, I am not so sanguine as he as to the results—that is, if he introduces the instrument in his own peculiar way. I may mention, however, that, considering the number of cases already successfully treated, and especially those reported by Dr. George Johnson and myself in the second number of *THE MEDICAL PRESS AND CIRCULAR*, I scarcely await his report with that anxiety which, I have no doubt, I should otherwise feel.

7. As regards Dr. Eben. Watson's method of laryngoscopy, I am quite amazed to learn that "it is not essentially different from Czermak's." It appears now that, instead of using "a range of houses" as a reflector, it is the "plate glass windows" in the range of houses that he thus curiously employs. Does he still carry out his eccentric method of warming the laryngeal mirror—viz., by allowing the patient to suck it? or, as he delicately puts it, "making him take the mirror into his mouth for a minute or two, when it becomes of such a temperature," &c. &c.

The readers of this journal will now be in a position to judge as regards Dr. Eben. Watson's mode of examination, the value of his revelations, and the justice of my remarks upon them. I have to add, in conclusion, that having, since the publication of my paper, received numerous inquiries from medical men in different parts of Ireland, as to where my galvanizer can be obtained, its price, &c., I beg to be allowed to add that it is sold by Mayer, 59, Great Portland-street, by Krohne, 241, Whitechapel-road, and by most other instrument-makers. It can be used with any electric machine. The price is ten shillings.

13, Weymouth-street, Portland-place, February 6, 1866.

THE APPARENT CAUSES OF FEVER AND CHOLERA.

By CHARLES F. MOORE, M.D., F.R.C.S.I.,

ONE OF THE PHYSICIANS TO CORK-STREET FEVER HOSPITAL, ETC.

THE distinction between typhus and typhoid fever is not, as it appears to me, very much to be relied on either as to its line of demarcation or in regard to prognosis, inasmuch as the latter may, by an easy transition, as owing to some accidental circumstance, pass into the former; also a person in the course of, or convalescent from, typhus may very readily be attacked with typhoid symptoms. Dr. Murchison, in his valuable work on fever, insists on the distinction between the two, quoting many very eminent authors in support of his views, at the same time that he admits the large array of authors who regard the two diseases as identical: but in using the word identity he goes much farther than I would, so perhaps there is not so much difference among those who are said to hold opposite views on the subject, and as it is not my wish to occupy either my own time or that of my readers in the discussion, I will simply state, that I think the two forms of disease, though differing in many points, may be fairly embraced under one head "fever," as they are in the registration of deaths in Ireland.

While, however, saying this much, I would not for a moment avoid impressing the leading features of each form of the disease on the profession, especially on the younger branches of it, in the hope that attention to these points may more often than has heretofore been the case lead to inquiry into the causes of each, with a view to the adoption, wherever possible, of preventive measures. Perhaps if we divide the more important continued fevers of

the United Kingdom into three classes, as my predecessor on the medical staff of Cork-street Fever Hospital (Dr. Hannah) did, we would form a more correct classification of the diseases under consideration.

Dr. Hannah designated fever as typhus, typhous, and typhoid, and it appears to me more true and comprehensive a nomenclature than that of typhus and typhoid—the intermediate expression, typhous, representing those cases presenting characters in common with typhus and typhoid. I have also been informed by another gentleman, whom I hope to quote at a future time, that in his experience the distinctions between typhus and typhoid are not generally well marked, and that in Dublin hospital practice he finds typhus the rule and typhoid the exception.

Before proceeding further I would very shortly premise that I regard typhus fever as generally the result of the overcrowding of persons whose antecedents of life, health, food, condition, &c., predisposed to it; whereas typhoid or pythogenic fever, as it has been called by Dr. Murchison, arises from what has usually been understood as malaria or miasm, the latter terms expressing a vitiated state of the air caused by the diffusion of gases, the result of putrescence.

I do not at present desire more than to allude to the various conditions which may intensify the noxious qualities of the atmosphere resulting from overcrowding, such as the low condition, from any of the numerous causes which may depress the systems of the persons crowded together, causes which may operate either by acting on the mind or on the body, or on both together; in like manner the bad air, constituting what we designate, by borrowing from another language, as malaria, may be caused by the presence of various minute organisms or organic particles in the air, soil, water, or in the materials of the habitations of the persons attacked with disease; or the decomposition may arise in substances of a much more tangible and apparent nature. Or, again, the vitiated air may obtain access to the persons affected through accidental causes or by agencies at a distance, as by currents of wind, by conduit of water, air, &c.; or again by the geological arrangement of the localities, the operation of tides, floods, the operation of capillary or other natural forces.

I am well aware that many persons even of great intelligence have often been at a loss to account for the occurrence of fever and other diseases where no evidence of decomposition may be apparent to the senses, more especially when the atmosphere is at a comparatively low temperature. This may, I think, be accounted for thus: water containing more or less organic substances in combination with moisture is constantly emitting watery vapour, the latter is always more or less impregnated with the gases resulting either from minute diffusion, solution, or decomposition of the organic matter, although to the senses at the low temperature of the atmosphere such impregnation may not be recognizable; but when the same air gains admission to a dwelling-house, and most of all to a sleeping-room—in short, when the admixture with and diffusion in the outer air is rigorously prevented by every available means, as is so constantly the case, then the noxious and hitherto latent miasm is rendered apparent and doubly injurious.

The same sequence of operation may act, I conceive, even in our bodies in the process of respiration. The moisture, carrying with it a certain amount of latent malaria, may pass the sentient nervous provision, which would warn us of a more palpable amount of noxious vapour, with little or no perception of its presence, and a slow degree of blood poisoning may proceed, even in the cold external air, which may prove injurious, if other favouring circumstances, such as over-fatigue, exhaustion, or subsequent exposure to more active miasm arise.

An instance such as this may be seen in persons who, though they take much active exercise, never seem to benefit to the extent one might reasonably expect, and whose complexions bear evidence to the fact. The explanation of this seems to be, that the air, such as that of

a confined playground, ball-alley, or racket-court, is not sufficiently pure and open to the peculiarly invigorating influence of sun and wind.

Indeed, I fear we do not sufficiently appreciate, as some at least of our predecessors did, the invaluable qualities of sunlight and fresh air as prophylactics, and in a curative point of view. The advice given to a lady in Dublin relative to the bringing up of her family by an eminent practitioner fifty years ago on this subject would not be out of place with many persons now a-days. It was in substance such as I have indicated above, and to its value in many different climes I can bear the most ample testimony.

Fever apparently commencing and persistently continuing in a locality.—When such an occurrence takes place it is not always easy to find a probable cause; it is, however, a matter of great importance to endeavour to ascertain all the particulars connected with the locality, in the hope that some cause may be discovered, and every effort should then be made to effect its removal.

The cause of disease may not be always distinctly referable to any one condition, but may, on the contrary, be referable to several agencies of no great individual importance. An instance of this kind may be given. The writer had charge of a ship's company, composed of English, Africans, and Lascars, and during a sojourn in the harbour of Hong Kong, in the month of July, one of the English sailors was attacked with dysentery. The commander of the ship was unwilling to accede to the advice to send the man on shore to hospital. However, when two other men were attacked with the same disease, he then saw the necessity of doing so, and after their removal the sickness ceased on board the ship. Now, I conceive that the cause of the first man's illness was irregularity of diet in a tropical climate in a man predisposed to dysentery by his previous habits, the rather crowded state of the seamen's quarters, and the climate; whereas the condition of that part of the ship being improved by removal of the three men, cleansing, &c., the disease did not spread to others who, from several circumstances to which they had been subjected as well as their comrades, would most likely have been also ill were it not for the improvement as to space, &c., effected on the removal on shore of the others.

Now, I have often observed the cessation of typhoid and other forms of fever on the removal of persons taken ill from houses evidently injuriously circumstanced as to malaria. From this and from other circumstances I infer that typhoid fever is contagious, and that it is promoted by crowding. Should, however, the latter be excessive, I think we may undoubtedly expect to find typhus arising where, under more favourable circumstances, we should have had typhoid or typhus fevers.

Although I have above stated my unwillingness to enter on the question of the exact relations between typhus and typhoid fevers as distinct as any two of exanthemata, typhoid fevers, I must protest against those who, following the ideas of Dr. Wm. Jenner, Dr. Stewart, and M. Gerhard are represented, no doubt accurately, by Dr. Murchison as regarding typhus and Let us inquire into Dr. Jenner's reasons on this matter. Dr. Murchison says:—By an analysis of all the cases admitted into the London Fever Hospital for more than two years, he showed that the two fevers did not prevail together, and that the one did not communicate the other. He also adduced cases to prove that an attack of the one fever protected from subsequent attacks of itself, but not of the other. From what has already been said, it may be inferred that my experience of fevers does not warrant me in regarding the two fevers at all in the state of non-relationship, so to speak, claimed for them by Dr. Jenner. At the same time, and I think I speak the opinion of the profession, not only in Dublin, but of many illustrious members of it elsewhere, the statement that the two fevers do not prevail—I presume in a generally epidemic form—together, by no means proves that typhus

and typhoid fevers are as dissimilar as two of the exanthemata. That typhus does not communicate typhoid fever can never prove that the latter bears no resemblance to it, but that typhoid may, under favouring circumstances, merge into typhus, as well as that the latter readily also assumes typhoid symptoms, rather proves the truth of those observers who years ago by their nomenclature pointed out the affinity existing between the two forms of illness.

MEDICAL ANALYSIS.

DESIGNED AS A GUIDE TO THE PRACTICAL DETERMINATION OF THE PURITY OF COMMERCIAL MEDICINES.

By CHAS. R. C. TICHBORNE, F.C.S.L.

CHEMIST TO THE APOTHECARIES' HALL OF IRELAND, ETC.

(Continued from Vol. LIII., page 510.)

ACIDUM HYDROCHLORICUM (*continued*).—The presence of free chlorine in hydrochloric acid is delicately determined by dropping in a small piece of silver leaf after diluting the acid. If chlorine is present the silver leaf will become instantly tarnished, and if exposed to the light for some time, this reaction will indicate the smallest possible trace of that substance. The presence of nitric acid does not vitiate the test, but it must be borne in mind that perchloride of iron produces the same effect if present. Iron may be detected by ferrocyanide of potassium, which gives a blue precipitate.

b 1. ACIDUM HYDROCHLORICUM DILUTUM.—The specific gravity of this acid should be 1.050. "Six fluid drachms require for neutralization ninety-nine measures of volumetric solution of soda."

b 2. ACIDUM NITRO-HYDROCHLORICUM DILUTUM.—The specific gravity of this is given as 1.074, and six fluid drachms are said to require for neutralization 93.88 measures of the volumetric solution of soda. Now, six fluid drachms contain nearly 4-10ths of a drachm of nitric acid, and 8-10ths of a drachm of hydrochloric acid.

This acid, however, varies very much, and is of a very uncertain composition. If recently made, and mixed as directed in the Pharmacopœia, it will contain no free chlorine, but will merely be what is probably a mechanical mixture of nitric and hydrochloric acids. It will not dissolve gold leaf in the cold, which demonstrates this fact; but if it has been made some time, or if the two acids have been mixed together before diluting one with water, the acids react upon each other, free chlorine is generated, and gold will be found to readily dissolve without applying heat. For the tests of purity of these acids, see respectively the articles "Hydrochloric Acid" and "Nitric Acid."

ACIDUM HYDROCYANICUM.—

Anhydrous hydrocyanic acid is a colourless liquid, having a specific gravity of 0.7058 at 60° Fahr. It is miscible with water in all proportions. It is extremely volatile. The medicinal acid only contains two per cent. of anhydrous acid, yet it is very poisonous. The smell of hydrocyanic acid is sometimes compared with the essential oil procured from bitter almonds, and as this oil generally contains a considerable amount of hydrocyanic acid, this will account for the descriptions given in medical and chemical works. There is, however, an aroma due to the essential oil which is entirely wanting in the acid, and, *vice versa*, the odour of the acid is quite distinct from that of the oil.

The peculiar acidity felt in the throat or the constriction of the fauces on smelling this acid is more marked than even the aroma itself.

Hydrocyanic acid is rarely if ever intentionally adulterated. It generally, however, contains a small quantity of some inorganic acid (hydrochloric or sulphuric); the

latter may be mechanically carried over in the distillation, or either of the mineral acids may be added intentionally to prevent the organic acid from decomposing.

The presence of either of these acids can be determined in the following manner:—

Hydrocyanic acid reddens litmus paper slightly, but, owing to the ready volatility of this substance, the litmus paper regains its original colour on drying. But if mineral or non-volatile acids are present, the paper remains permanently red. If the salt is at hand, Geoghegan's pretty test may be used for the same purpose. This consists in the adding of the double salt of cyanide of mercury and iodide of potassium ("hydrargyro-iodocyanide of potassium") to the hydrocyanic acid to be examined. The presence of a mineral acid is rendered evident by the instantaneous formation of the red iodide of mercury.

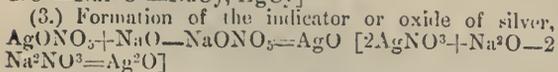

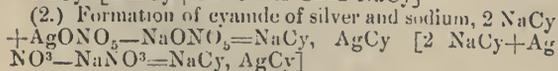

The acid used is generally sulphuric, sometimes hydrochloric. The presence of the first is easily determined by chloride of barium, which gives a white precipitate if it is present; but the detection of hydrochloric in hydrocyanic acid is not quite so easy. A very small quantity of the precipitate, procured on the addition of nitrate of silver to the suspected acid, is transferred to a test-tube, and some considerable quantity of nitric acid (specific gravity 1.500) added, and boiled for some time. The cyanide of silver is decomposed with the evolution of carbonic acid, whilst the presence of hydrochloric acid will be rendered evident by a white precipitate of chloride of silver remaining.

Hydrocyanic acid is liable to great variations in strength—a matter of great importance with so powerful a medicine. Sometimes this proceeds from carelessness in proportioning the water after distillation, or more frequently from the fact, that hydrocyanic acid rapidly loses strength from its very volatile nature. Luckily, however, the estimation of hydrocyanic acid is easy of execution, and, with ordinary care, gives very exact results. The Pharmacopœial acid should contain two per cent. Scheele's acid contains a very variable percentage. Some years ago it was customary to send this acid out containing five per cent., but of late years it seems to have been reduced to four, probably from the circumstance that it was only necessary to add its bulk of water to make the two per cent. acid.

The estimating of hydrocyanic acid is best performed by the method suggested by Liebig, and adopted in the present Pharmacopœia. The specific gravity is not a guarantee of the strength of the acid, unless very carefully taken with very delicate instruments.

The test is that half a fluid ounce of the acid, when treated with an excess of a solution of soda, requires the addition of 80.66 measures of the volumetric solution of nitrate of silver. One atom of the cyanide of silver, formed upon the addition of volumetric solution, combines with another atom of cyanide of soda to produce a double salt. Therefore, as long as there is any hydrocyanic acid present, no precipitate is produced; but when sufficient nitrate of silver has been added, the excess is decomposed by the soda present, and oxide of silver is thrown down. Thus a turbidity is indicative of the conclusion of the experiment. The three reactions which take place would be represented by the following equations:—

The volumetric solution of nitrate of silver is a decinomial solution—that is to say, contains 1-10th of an equivalent of nitrate of silver in grains, in each 100 measures.*

From the reaction it is seen that one equivalent of nitrate of silver equals two equivalents of hydrocyanic acid

($2 \text{ Na Cy} + \text{AgONO}_3 = \text{NaO, NO}_3 + \text{Na Cy, Ag Cy}$), and as the equivalent of hydrocyanic acid is 27. $\therefore \frac{27}{10} = 100$

degrees of nitrate of silver solution, or

$$\frac{5.4 \cdot \Delta}{100} = x$$

A being the number of degrees of the silver solution used, x will be the amount of absolute hydrocyanic acid present. If it is desirable to weigh the cyanide of silver, the weight divided by five will give about the amount of hydrocyanic acid present.

The following are accidental impurities occasionally found in hydrocyanic acid, but not in sufficient quantities to merit any further comment:—the cyanides of iron, formate of ammonia, and bitartrate of potash. The latter is found in acid made by Dr. C. Clark's method—viz., by the decomposition of cyanide of potassium by tartaric acid, but the method is never pursued in commerce.

Hydrocyanic acid should be completely volatilized by heat.

ACIDUM NITRICUM.—

Pure nitric acid is a corrosive, colourless, mobile liquid, of specific gravity 1.520. The strong and diluted acid stains the cuticle a permanent yellow colour, which is not obliterated by alkalis, as is the stain from iodine, which it somewhat resembles, but, on the contrary, it is deepened by them to a bright orange. In the presence of the ordinary atmosphere it gives off white vapours of an acid and corrosive nature. This description does not apply, of course, to very diluted acids.

The admixture of pure nitric acid with water gives rise to the evolution of heat, and the production of a definite hydrate of two equivalents of acid to three equivalents of water. $2 \text{ HNO}_3, 3 \text{ H}_2\text{O} [2 \text{ H}^2\text{ON}^2\text{O}^3, 3 \text{ H}^2\text{O}]$. This acid has a specific gravity of 1.420. It seems to be the normal state of nitric acid, if we may use such a term, as weaker or stronger acids are alike brought to this composition on boiling—the weaker acid losing water and a stronger acid losing the elements of nitric anhydride, $\text{NO}_3 [\text{N}^2\text{O}^2]$.

There are two kinds of acid met with in commerce, which, although they may be considered practically pure, differ in appearance from the above description of chemically pure nitric acid. Instead of being colourless they are tinged from pernitric oxide. The first of these is the ordinary 1.500 specific gravity acid, which suffers partial decomposition from the light, and generates sufficient peroxide of nitrogen to colour the acid yellow. The second is the fuming nitric acid of commerce, sometimes called nitrous acid. This is nitric acid, containing a considerable quantity of pernitric oxide intentionally introduced during the process of manufacturing. It is preferred in the arts for some purposes, being a more powerful oxidizer.

Nitric acid should be perfectly volatile. After the determination of this point, by evaporating a few drops upon a watch glass, the specific gravity may be taken as a criterion of its strength.

* Volumetric Solution of Nitrate of Silver, B.P. "A mixture of Silver = 170." "Take of nitrate of silver, 148.75 grains; distilled water, one pint. Dissolve, and keep in an opaque stoppered bottle. The quantity of this solution which fills the volumetric tube to 0 includes seven cent grains of nitrate of silver, or 1-10th of an equivalent of this salt in grains."

INDIAN BRANDEE.—A child, named Emma Longfellow, aged eight weeks, died at Leeds from the effects of a penny-worth of Indian brandee administered to her by her mother as a cure for diarrhoea. Mr. Brameld, surgeon, stated that the "Indian brandee" is a most pernicious article, being composed partly of naphtha. The inquest held on the child was adjourned in order to have the "brandee" analysed.

DR. RICHARD SCHOMBURG, brother of Sir Robert, has been appointed director of the Botanic Garden of Adelaide.

HOSPITAL REPORTS.

KING'S COLLEGE HOSPITAL.

Communicated by Dr. G. de GORREQUER GRIFFITH,
PHYSICIAN TO THE INSTITUTE FOR WOMEN AND CHILDREN, ETC.

The first case was a patient, under the care of Mr. Henry Smith, and submitted to operation because of a tumour or swelling on the right shoulder.

The history attached to the case is as follows:—The patient, a woman, for the first time noticed a swelling about four years ago in the site of the present tumour: this swelling very gradually increased in size till it attained its present dimensions, which are equal to those of a small orange. Within the last ten days there had been a good deal of pain, as if suppurative action had taken place.

Before Mr. Smith began the operation, he mentioned that he was uncertain whether the swelling was a chronic abscess or a tumour, using this latter word in its strict signification, and implying an abnormal solid growth, fatty, or otherwise.

While pointing out the symptoms which would lead to the supposition that it was a tumour which lay beneath the integument—there being a certain degree of consistence and firmness appertaining to the swelling, along with great mobility underneath the skin and upon the subjacent muscles, coupled with the length of time which had elapsed from the first appearance, and which the swelling had taken to develop itself.

Mr. Smith dwelt particularly upon the sense of fluctuation which could be appreciated by the finger, upon the acute pain felt within the last ten days, the peculiar elasticity, of the consistence and firmness, and stated that, although the diagnosis was very uncertain, he should not be at all surprised if the affection should prove to be a chronic abscess, even of four years' duration.

With his operating scalpel he made an exploratory puncture into the centre of the swelling, and forthwith there issued thin and healthy pus.

The abscess having been emptied, a compress of lint was applied by means of adhesive plaster and bandage, in order to prevent a re-collection of matter.

Mr. Smith then mentioned a case in which an operating surgeon of eminence had asked him to be present at the removal of a tumour from the axilla. The tumour had been present for two years; the operation being expected to be of a serious nature, owing to the number of vessels in the axillary region. There was a goodly supply of assistants. The surgeon, without having first made an exploratory incision, divided the integument and the subjacent tissues till he came upon and cut into—not an axillary tumour—but a simple chronic abscess in the axilla.

CLEFT PALATE—OPERATION BY SIR WM. FERGUSSON.

Case 2.—This was a young woman of about 18, who had had hare-lip, combined with great deformity of the nose. The hare-lip, and, in a great measure, the deformity of the nose, had been rectified by a previous operation. As there existed a fissure in the hard and soft palate, in addition to the deformities above described, another operation had been resorted to in order to cure this malformation also, and so far as the hard palate was concerned, the operation was most successful; but the cleft in the soft had not been repaired, although for the few days succeeding the operation, and while the stitches had been allowed to remain in, it seemed to have been so. As soon as the stitches had been taken out the mere weight of the palate had created the cleft afresh, and that even through the margins of the fissure had been pared, nicely and accurately apposed, and glued together by adhesive inflammation. The adhesion, Sir Wm. Fergusson remarked, must have been slight, and the imperfection have arisen

from some defect of the constitution, and not from any undue strain upon the palate, since such had been prevented by the care exercised in the treatment after the stitches had been removed.

That part of the velum which forms the uvula, as well as that which lies immediately in front of it, had remained undivided since the operation had been practised.

The operation consisted merely in paring or roughening the margins of the existing fissure, and then again stitching them together.

Sir Wm. Fergusson remarked that in cases where the wound gapes when the stitches are being removed, or have been recently removed, he at once scrapes the margins of the gap and brings them together again by means of the stitches. In instances of hare-lip he adopts the same practice.

TYING THE FEMORAL ARTERY FOR POPLITEAL ANEURISM.

OPERATION BY SIR WM. FERGUSSON.

Case 3.—The patient was a young delicate-looking man, of slender build. There was a peculiar anxiety of look in his face. Owing to the existence of an abnormal condition in the heart and aorta the operation was not proceeded with till a careful examination had been made of the organ and bloodvessels affected. Chloroform was then administered, and no bad effects resulted from it.

The artery (superficial femoral) was cut down upon in the upper third of the thigh; the length of the incision being about four inches. The edge of the sartorius was sought and found, was drawn outwards, the fascia and sheath of the vessels carefully cut through, the threaded aneurism needle passed from above and within downwards and outwards, till the point came upwards on the outer side of the artery, when that vessel was tied.

Neither the femoral nor the saphena vein gave any trouble, nor was the saphena nerve at all seen during the steps of the proceedings.

The wound in the integument was united by means of thread sutures; a compress was laid over the wound, and was maintained in its place by means of strapping and a bandage.

The aneurism seemed to be of large size, but the flow of blood through it was immediately checked when the ligature was tightened around the artery.

Tying the femoral artery for popliteal aneurism is in those days of compression a rare procedure. In the present instance it had to be done, because compression by forcible extension, by forcible flexion, and by the tourniquet, could not be borne sufficiently long to effect a cure.

The first plan named—viz., compression by forcible extension—was first practised in King's College Hospital. It consists in straightening the limb as much as possible. This had been attempted to be done in the case before us; but owing to the habit of flexion, and the great degree of flexion into which the limb had fallen, the patient was not able to endure the pain experienced by the extension.

When the patient was put to bed the limb was carefully wrapped in cotton wool, in order, as much as possible, to preserve the temperature.

THE CHOLERA CONFERENCE.—Dr. Goodeve is to be the English medical colleague of the Hon. W. Stuart; Salih Effendi, director of the Medical School at Koombarhané, and Dr. Bartoletti, member of the Board of Health, to represent the Porte; Drs. Pelikan and Bykow, and Mr. Lintz to represent Russia; Drs. Greisinger and Herch to be the Prussian representatives; and Dr. Salvatore, with the Chev. Jerponi, first dragoman of the Italian Legation.

THE QUEEN'S PHYSICIAN AND THE OPENING OF PARLIAMENT.—Orders were given to the police, on Tuesday week to permit the carriage of Dr. Jenner to follow in the Royal procession *en route* to the opening of Parliament by the Queen.

Foreign Medical Literature.

ON PATHOLOGICAL CHANGES OF THE PULMONARY ARTERY AND OF ITS VALVES.

By Dr. P. Q. BRONDGEEST.

Translated from the *Nederlandsch Archief voor Genees- en Natuurkunde*, 1e Deel, 2e Aflevering, Utrecht, 1864, for THE MEDICAL PRESS AND CIRCULAR.

By WILLIAM DANIEL MOORE, M.D. Dub., M.R.I.A.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS, OF THE NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

(Continued from page 567.)

THE principal writers on diseases of the heart agree in this, that the lesions of the pulmonary artery and of its valves are among the rarest abnormalities which we observe at the bedside. Thus Stokes* thinks that the difference in the frequency of the occurrence of valvular lesions of the right and left side of the heart is so great that in practical medicine we may confine ourselves to the consideration of defects of the latter, and Bamberger writes respecting the former†:—"Their diagnosis is by no means difficult, only the rarity of these affections is so great that in a given case we would rather endeavour to explain the phenomena in any other possible way.

In fact, special circumstances must exist to lead us to suspect the presence of such a lesion if we are not to be surprised at the discovery of a considerable morbid change in the pulmonary artery in the dead body. Now, since the year 1861 two cases have occurred in the hospital at Utrecht. The first relates to a change in the valves of the pulmonary artery, combined with their partial destruction; the second to an atheromatous degeneration of the arterial wall, with nearly complete embolism of the branches and great hypertrophy of the right side of the heart. I shall communicate the leading peculiarities of these cases, and, in conclusion, compare them with those already known.

I. EXCRESCENCES ON THE VALVES OF THE PULMONARY ARTERY, WITH DESTRUCTION OF ONE OF THE VALVES.—This case was observed in a man, aged 29, admitted into the hospital on the 22nd July, 1861. The countenance was pale and swollen; the feet were œdematous. Auscultation and percussion afforded no signs of pulmonary or heart disease. The respiration was normal; the pulse was slow and regular. The urine contained a large quantity of albumen, also fibrin cylinders and epithelial cells passing into a state of fatty degeneration. Chronic Bright's disease was, in this instance, suspected to exist. After treatment had been continued the abdomen, too, began to swell and ascites set in. The urine still contained albumen. Subsequently violent diarrhoea supervened, under the effects of which the patient sank on the 12th October without any disturbance in the functions of respiration and circulation having been observed.

The post-mortem examination was made in twenty-four hours after death.

The cavity of the cranium presented no peculiarities. The brain and its membranes were normal.

Thorax.—The chest contained a small quantity of clear serum. The lungs collapsed on the opening of the cavity; the left lung appeared, as well as the right, to consist of three lobes. The pleura-pulmonalis of the right lung was adherent postero-inferiorly to the pleura costalis. Both lungs crepitated when cut into, and floated in water. From the lower lobes of both a red frothy fluid exuded on section. The heart was not enlarged, and it occupied the

* Stokes, *Diseases of the Heart and the Aorta*, Dublin, 1854, p. 163.

† Virchow's *Archiv*, Bd. 9, p. 544.

usual position. The left ventricle was capacious; the mitral valves were in their normal state. Neither did the semilunar valves of the aorta exhibit any abnormality. The inner surface of the aorta was smooth, with the exception of a few places, where some yellow-coloured, slightly elevated spots of the size of a pin's head were found. Placed in rows, they presented the appearance of stripes. On microscopical examination they were seen to depend on the deposition of fat. The right auricle and ventricle were dilated; their walls were not thickened. The tricuspid valves were normal. The valves of the pulmonary artery, on the contrary, exhibited a considerable morbid change (see plate IV., fig. 4).* That situated most to the left (when the position which it has in the body was given to the heart) was attached to the arterial wall by a viscid purulent mass, and at this side, as well as at its free margin, it was covered with numerous condylomatous excrescences of various sizes and shapes. The largest two presented a conical form: a broad base and a pointed extremity, turned upwards. Their breadth amounted to about 5 (-19685"), their length to 10 millimetres (39370"). In the place where the excrescences lay against the wall of the artery the latter exhibited an ulcerated spot, with sharp edges, and covered with purulent matter. The inner and middle coats of the artery, which was here very much attenuated, appeared to be annihilated. The side of the valve looking towards the heart was smooth. The middle valve presented but little change; only at the base were there some slighter depositions united into a spot, also on the endocardium of the right ventricle under this valve. The third, finally, situated most to the right, was almost wholly destroyed. Of this only a trace was to be found, consisting of a small part of the base and some small hard deposits, arranged in a crescentic form. The valve that still remained, presented the appearance of being partially ulcerated. Above this valve the wall of the artery was likewise thinner. In the artery itself no further morbid deposits were observed, nor was there any embolic obstruction of its branches. The excrescences consisted of an unorganised caseous mass, which swelled up in dilute hydrochloric acid with the development of gaseous bubbles.

Abdomen.—The liver was congested, the spleen soft. The pancreas was normal. The small intestines presented no abnormality. In the rectum were some small, very superficial round ulcerations. The urine found in the bladder was albuminous; the deposit contained epithelial cells in a state of fatty metamorphosis, also pale fibrin cylinders. The kidneys were large, pale, and of a yellowish appearance. On the surface they exhibited some ruptured bloodvessels. The epithelium of the tubuli uriniferi presented traces of fatty metamorphosis.

The pathological condition of the valves of the pulmonary artery here described was evidently the result of an inflammation, which had been confined almost exclusively to the valves, and chiefly to the surface looking to the wall of the artery. The inequality resulting therefrom further occasioned the deposition of fibrin from the blood, which passed into softening and caused destruction of the right valve. Of such a condition of the valves insufficiency must necessarily be the result. Stenosis probably did not exist.

As we said in the commencement, changes such as those here described are often enough met with in the semilunar valves of the aorta, but very seldom in those of the pulmonary artery. In the first place, inflammation in the right side of the heart is extremely rare, and it appears that even where roughness is produced thereby, further deposition from the blood does not very readily take place. The well-known case described by Dietrich† agrees in some points with the above. In his case a ring-shaped

* I have allowed the reference to the plate to remain, as the other figures contained in it illustrate a paper on the pathology of cystoid kidney, which I have marked for translation if I can procure the plate from Holland.—*Translator*.

† Dietrich, *Prager Vierteljahrsschrift*, Bd. 1, p. 157.

stenosis of the conus arteriosus had taken place beneath the valves of the pulmonary artery in consequence of acute myocarditis, and the valves of the artery were studded with fine granular and warty excrescences, partly connected with one another, partly isolated. These, however, were not, as in our case, situated on the side of the valve turned towards the arterial wall, but towards the cavity of the artery, and they extended to the place where the constriction existed. The valves, moreover, were still present in their integrity. Dietl* states that in the hospital at Vienna there are two preparations—one taken from a youth, where there was insufficiency of the valves, in consequence of a very acute exudative process, with softening, displacement, and partial destruction of the valves. This pathological condition presents much analogy to that observed by us. The second is described by Benedict,† and was obtained from the body of a woman aged 60, whom he had seen also during life. In this instance the semilunar valves were much thickened, had coalesced with one another at the edges, and were completely inverted so as to present a concave surface upwards. The orifice was so constricted that only the top of the finger could be introduced through it. On the inner coat were many atheromatous depositions. Ferriehs‡ has described a case where insufficiency of the semilunar valves was combined with constriction of the ostium arteriosum of the right side of the heart.

Pathological conditions of the valves of the pulmonary artery are observed also in cases of communication between the two sides of the heart. Bertin§ records two cases of this nature, one observed by himself, the other communicated to him by Louis. In the first the cavities of the right side of the heart were found, in a woman aged 57, very much hypertrophied, and the orifice of the pulmonary artery was closed at the base of the valve by a horizontal plate, in which only an opening of two and a-half lines in diameter existed. The ductus arteriosus Botalli was still open. In the second case there was a small opening between the aorta and the base of the right auricle, while the semilunar valves of the pulmonary artery, having grown together, formed an edge by which the orifice was constricted, leaving an opening of only two and a-half lines. The person, a bricklayer, in whom this was observed, was 25 years old.

Stokes,|| too, mentions a case, observed by Gordon, of insufficiency of the valves of the pulmonary artery, combined with communication between the two sides of the heart. The valves were found thickened, shortened, opaque, leaving a gaping opening, through which water poured in ran. In the interauricular septum was an oval opening, the longest diameter of which was three-fourths of an inch.

Lastly, Speer has accurately described a case which occurred in a girl, aged 17.¶ In this instance the orifice of the pulmonary artery was so constricted, in consequence of the valves growing into a cartilaginous ring, that only a fine catheter could be introduced through the opening. The foramen ovale was open.

The case recorded by me is thus distinguished from all others by the fact that no remarkable constriction existed, and that there was no communication between the right and the left sides of the heart. It is important to observe this, as it is hence evident that auscultation could not yield the phenomena observed where constriction coexists, and which would lead one to suspect the presence of a pathological condition of the pulmonary artery and of its valves. We have accordingly also seen, that in all cases diagnosed during life, stenosis of the orifice had existed. It is, moreover, remarkable that the same pathological conditions,

which in the left side of the heart produce symptoms of great disturbance in the circulation, may exist almost unobserved in the right side.

II. EMBOLISM OF THE RIGHT BRANCH OF THE PULMONARY ARTERY, WITH DILATATION OF THE LEFT, COMBINED WITH HYPERTROPHY OF THE RIGHT SIDE OF THE HEART.—J. B., aged 58, was admitted into the hospital at Utrecht, on the 17th December, 1860, under the care of Dr. Imans. He was a strong person, a hod-man by occupation, which employment he was obliged to give up on account of shortness of breathing and of intolerable palpitations of the heart. His pulse was very rapid. On physical examination dulness on percussion and a crepitating murmur were found to exist in the inferior portion of the left lung. There was, moreover, enlargement of the heart. On auscultation at the apex of that organ it was ascertained that the first sound was replaced by a strong systolic, prolonged, rough bellows murmur; the second sound was indistinctly heard. The existence of endocarditis was suspected, with deposition on the mitral valve, and pneumonia of the lower lobe of the left lung. Free venesection and the administration of digitalis were productive of relief. On examining the patient in the beginning of February, 1861, we found hypertrophy of the heart, strong cardiac impulse, dyspnoea and oppression. From the sphygmographic tracing of the radial artery it appeared that the pulse, which was not rapid, was somewhat irregular both in rhythm and intensity. In connexion with the auscultatory phenomena it was considered that there was a slight insufficiency of the bicuspid valve, while we did not understand, how with the strong bellows murmur, indicating a remarkable change in the structure of this valve, the current of blood had undergone so slight a modification. The patient left the hospital on the 23rd of February, 1861, feeling somewhat better. In the winter of 1862 he again presented himself, complaining of violent palpitations of the heart, with oppression; œdema of the feet had now supervened, and his state was on the whole altered for the worse. The sphygmographic tracing, however, continued the same. This was also in part true of the auscultatory signs. The systolic bellows murmur was still present, while it was to be heard more diffusely over the region of the heart, and at the left edge of the sternum, at the attachment of the cartilage of the fourth rib, more distinctly than at the right side, at about the same height. No diastolic sound or murmur was perceptible. It was now remarked that the external jugular vein distinctly pulsated. The case, however, continued obscure, and the phenomena were not explicable by the assumed existence of an abnormality of the left side of the heart. It was therefore supposed that the right side of the heart, or the pulmonary artery, was the seat of a morbid change. This supposition was based principally upon the following considerations:—

1st.—That the disturbances in the general circulation were not of such a nature as to account for the œdema of the feet, the dyspnoea and oppression.

2ndly.—That the murmur existing at the apex of the heart was particularly loud also in the middle of the sternum, and on the left side, on a level with the fourth rib, and that, therefore, it might be produced by an abnormal condition of the venous or arterial orifice of the right side of the heart.

After some time the patient again left the hospital because his state was not improved. We heard that some time later, after having, by the advice of some of his friends, used juniper, with the inner bark of the elder, he was considerably better. For two years we heard no more of him, until, on the 20th of August, 1864, he was again admitted into hospital.

His condition appeared to be then very much worse. The oppression and dyspnoea were much greater; the pulse was very frequent; the hands and feet were œdematous; there was also even some ascites; the urinary secretion was scanty. The murmurs in the cardiac region presented the same character as before, and were again

perceptible in the place corresponding to the pulmonary artery, on a level with the fourth rib, more strongly at the left than at the right side of the sternum.

Soon after the patient died, and we found, on post-mortem examination, which was performed on the 9th of September, twenty hours after death, the following:—

Thorax.—On opening the thorax the lungs were seen only slightly to cover the heart, which was very much enlarged. The latter, in fact, was uncovered through a space of about $1\frac{1}{2}$ hands' breadth. The pleura-pulmonalis of the right lung was strongly adherent to the pleura-costalis, and likewise everywhere to the pericardium. The tissue of the right lung was tough, the lung itself was small and contained but little air, and only a small quantity of blood. The upper lobe was less compressed than the lower. The latter contained very little air. The bronchi were, on section, very distinctly visible. In the ramifications of the pulmonary artery were found old, whitish-yellow firm emboli. The left lung was free, highly compressed, slightly oedematous, and contained but little blood; the position of the heart was altered; the apex lay farther to the left; the right ventricle lay quite across upon the diaphragm; the right auricle and right ventricle were very much hypertrophied. The former was very much dilated. In the right branch of the pulmonary artery was an old, firm, whitish-yellow plug, adherent to the wall of the vessel and leaving only a small space for the blood; the plug was situated exactly where the artery divides into its pulmonary branches and was continued into them. Farther from the trunk the artery was empty, but exhibited thickened yellowish spots: the left ventricle was dilated. On the upper surface of the aortic valve was a thickened and elongated portion, which hung freely downwards from the valve, and was furnished with tendinous appendices. The semi-lunar valves and the aorta were normal; the pericardium was everywhere strongly adherent to the surface of the heart.

In the *abdomen* were from ten to twelve ounces of turbid serum. With the exception of the liver, which was small and in the incipient stage of cirrhotic atrophy, the organs of this cavity presented nothing remarkable.

Can we, from the morbid changes observed on post-mortem examination, account for the phenomena presented during life? The oppressed breathing and the dyspnoea are certainly sufficiently explained by the condition of the lungs and of the heart. The large and hypertrophied heart must, in the first place, have produced pressure upon the lungs and windpipe; and in the second, the respiratory process must have been very much impeded in the lung whose arterial trunk was obstructed.

The plug in the right branch of the pulmonary artery presented a considerable impediment to the lesser circulation, and, consequently, gave rise to hypertrophy of the right side of the heart and to the several dropsical conditions above described.

The conditions for the production of the murmurs observed in the heart appear likewise to have been found. The appendix to the bicuspid valve may, on the sudden closing of the valve, have been thrown into vibration, and thus the murmur observed at the apex of the heart may have been produced, while the murmur to be heard at the left side of the sternum, at the edge of the cartilage of the fourth rib, as well as at the right of the sternum at the same height—also a systolic murmur—may have depended on the pathological condition of the pulmonary artery. The pressing, too, of the blood through the very narrow opening existing between the plug and the artery, and the friction of the blood along the rough walls of the dilated left branch, may be remarked in explanation of this murmur.

We have in particular to direct attention to the advantage derived in this case from the employment of the sphygmograph. It showed, in fact, that the current of blood in the system of the aorta had undergone no remarkable modification, and thus the suspicion of a pathological condition of the right side of the heart, or of the

pulmonary artery, was excited. Had we not had this indication we might, in connexion with the auscultatory signs, have incorrectly diagnosed a considerable insufficiency of the bicuspid valve.

To the present time only three cases have been observed in which the trunk of the pulmonary artery was in such a pathological condition.

In Stokes* we find mention made of a case observed by Hope, where after death great dilatation of the pulmonary artery was discovered. In life a very strong sawing murmur had been heard between the cartilages of the second and third ribs, on the left side, which was propagated over the whole cardiac region. A second case was accurately described by Erichsen.† On auscultation the following phenomena were observed:—A systolic bellows murmur opposite the apex of the heart, in place of the first sound; the second sound weak but pure. In the second intercostal space a systolic and diastolic buzzing murmur. On opening the body two aneurisms of the pulmonary artery were met with, separated by a deep constriction, which was situated one centimètre ($\cdot 3937''$) above the edge of the valves of the pulmonary artery. In addition, the tricuspid valves were thickened at their edges, corrugated and shortened, and the bicuspid valves were studded with numerous vegetations. Lastly, Skoda‡ observed, in a man of 43 years of age, a case of aneurism of the size of a goose-egg, while the calibre of the two branches of the pulmonary artery was reduced to the thickness of a crow quill. During life there was a systolic bellows murmur in the ventricle, while at the base of the heart the sounds were scarcely audible. Anatomically this case presents the greatest analogy to the one above recorded.

ECLAMPSIA

(GRAVIDARUM ET PARTURIENTUM)

AT EIGHT AND A-HALF MONTHS' PREGNANCY,

BECOMING MUCH AGGRAVATED AFTER PARTURITION :

CHLOROFORM: CURE.

By Dr MASUREL.

(From the *Bulletin Médical du Nord de la France.*)

Translated by WILLIAM CRONIN HORGAN, M.D. Univ. St. Andrews.

MADAME D.—, 45 years of age, of a lymphatic temperament, and in delicate health for a very long time. She had been pregnant four times previously. Two confinements took place prematurely, and the children in both instances were dead. The child of the third pregnancy came to its natural time and was healthy, but it died of convulsions in three months after its birth. There survived a little girl, aged six years, the fruit of the fourth confinement, and who, though well-looking, had, about fifteen months ago, convulsions, of which she was perfectly cured. In this last confinement Madame D.—, according to her husband's explanations, suffered from suffocations, which ended when the confinement was over. The history of her case, which I then learned, make me believe that at that time there was a real nervous crisis, but the details are quite insufficient to form a fixed idea as to its exact nature.

When I was called upon the 4th October, at eleven o'clock p.m., Madame D.— is eight and a-half months' pregnant. Having sat up to satisfy the calls of nature she fell heavily to the ground, and was so prostrated that her husband thought she was dead. She did not recover her senses till she was again put into bed. It is, then, in that

* *Op. cit.*, p. 169.

† *Petersburger Medicinische Zeitschrift* 1 Jahrgang, 1862, p. 89.

‡ *Abhandlung über Percussion und Auscultation* 6te Auflage, p. 334.

position I find her, lying on her back; she is very feeble, complains of headache and pains in the chest. Her countenance is pale, anxious, though stupid-looking. The lower extremities, especially the right, are œdematous; the right hand and forearm are so, too, but to a lesser extent; her state is evidently chlorotic (*chloro-œmémique*). Neither the motions of the infant nor the beatings of its heart are any longer perceived. The os uteri is exactly in the same state as in that of a female at eight and a-half months' pregnancy; there is no symptom of labour. The development of the uterus is normal. The following prescription is ordered:—

Sulphuric æther	2 grammes.
Essence of mint	20 "
Cherry laurel water	20 "
*Linden tree water	120 "
Syrup of poppies	32 " Mix.

I myself administered spoonful of the foregoing mixture every quarter of an hour, and made her use chloroform inhalations. My patient is quite unwilling to take the mixture, as she pretends she is in great torture when attempting to swallow. There is in reality great difficulty of deglutition, and she is not able to swallow a table-spoonful till after having made from seven to eight attempts to do so. On the same account the chloroform inhalations are incomplete. However, at midnight I leave my patient in a pretty fair state.

On the 5th, at half-past four o'clock a.m., I am called upon and witness then a real attack of eclampsia. The face is the principal part engaged; it is pallid and has a real epileptic figure; the mouth, completely distorted, spews forth a sanguinolent froth. This condition lasts about ten minutes or so, and is followed by prostration, accompanied with stertorous respiration and inability to recognise anything. During the attack I repeat the chloroform inhalations; I also order cold water applications to the forehead and apply sinapisms to the extremities. As soon as consciousness returns I repeat the mixture above ordered.

At the end of an hour no new attack coming on I retire, ordering the mixture and cold applications to be continued, and giving directions that I should be sent for in case a new attack should come on.

At eight o'clock a.m. I again see my patient, who is perfectly unconscious; the eyelids are closed and the globes of the eyes are fixed and immovable. I then, for the first time, see an icteroid appearance, well marked, and which, according to the assistants in the room, did not exist the day before. She passed no water; I was near her about a quarter of an hour when she opens the eyelids; she moves her head gently to the right side; the eyeballs are convulsed from above to the right side, and the convulsions of the face recommence more violently than before, and are confined to the right side; I repeat the chloroform inhalations and a loss of consciousness immediately takes place; cold water is sprinkled on the face; sinapisms are renewed, and, notwithstanding, the patient becomes conscious for a few minutes only. One attack follows another and causes great prostration.

At ten o'clock the patient became conscious; I then left her and gave orders that I should be sent for if at all required. At this time the fœtus has given no indications of vitality; no symptoms of labour are present. However, the os uteri is half open; the finger penetrates freely to the membranes.

At half-past twelve o'clock two new attacks have taken place in my absence; I was sent for, and not being at home a brother practitioner (Feron) arrived and found the infant dead between the thighs of the patient. The confinement took place without any trouble. I am told that Madame D— has only used those words—"you hurt me," and endeavoured to turn off, as it were instinctively, the hands of the accoucheur.

A little time after being delivered, a new attack comes,

* *Tilia*, the lime or linden tree, has flowers which are supposed to possess anodyne and antispasmodic virtues.

on, more severe and more prolonged than any other. This time the whole body participates therein, but it yields, like the preceding ones, to the same treatment. The patient is in the same condition as before after the attack; sinapisms are applied to the forearms. Up to nine o'clock in the evening my patient is not conscious for a single moment; attacks take place from hour to hour, and sometimes oftener, in despite of repeated inhalations of chloroform.

October 6th, eight o'clock a.m.: No attack since nine o'clock yesterday evening; she passed the night quietly, but sensibility is not yet returned. Respiration is stertorous; the eyes are rigidly fixed; the icteroid hue and œdema are as before; there is some instinctive attempt at deglutition. She is ordered barley-water, with 0.5 décig. of nitre, two drops of croton oil in honey; the antispasmodic mixture and inhalations of chloroform.

Midday: She is in the same state; she drank, however, a little ptisan and passed water for the first time since she got sick; she spit out the greater part of the purgative liquid, and no evacuation from the bowels as yet took place. I ordered her the same ptisan and mixture, careful inhalations of chloroform and carbonate of magnesia.

At nine o'clock p.m. the patient has drunk well and passed water; the bowels were once moved; her condition otherwise is the same, except that the prostration is not so great. I ordered the same as above.

7th, eight o'clock a.m.: She passed a quiet night; she answers "yes" and "no," but she recognises no person; her eyes are fixed without expression; her face is stupid-looking. The urine of the previous day, when analyzed, is found to contain no albumen. I prescribed as before, barley-water with nitre; the antispasmodic mixture and veal bro'h.

Eight o'clock p.m.: She passed a quiet day; same expression of countenance; the eyes are movable but without expression, and unable to see. She has had one motion from the bowels and passed some urine; she sat up to obey the calls of nature, but her movements are more automatic than guided by intelligence. The same treatment is persevered in.

8th, half past seven o'clock a.m.: My patient recognises her husband and child; she also knows me, but no other person; her look is strange, and her speech is drawling and uncertain; I order, in addition, a little chicken broth in the evening.

9th, eight o'clock a.m.: Her sight is better, speech easier, and more flipant; she knows her attendants for a few minutes only; œdema in the extremities less, and completely gone from the upper members; the icterical tint or hue is disappearing; I prescribe the same medication; beef tea and chicken broth.

10th, in the morning: Her appearance natural, speech perfect, but still drawling; the patient inquires of her husband what took place, and asks if she was not *œdicente* before she got sick; she receives some evasive reply, and asks no more questions in consequence; some medication, beef tea, panado, and chicken broth.

10th, in the evening: Her confinement could no longer be concealed from her; she complains of headache, abdominal pains; has a feverish pulse and a hot and moist skin; I order, in addition to the ordinary prescription pills, composed of

Sulphate of quinine	0.1 décig.
Extract of opium	0.1 décig.

for one pill; one every three hours.

11th: A real attack of intermittent fever took place; a short intermission, one hour at farthest, I am told, followed; I find this morning my patient in the same state as the day before; same prescription as before.

15th: The jaundice has nearly altogether disappeared; so have the abdominal pains; headache is less; her countenance, speech, &c., are better, and she is much improved in every way except being a little feverish; I prescribe thick soup and egg; also the following:

Arsenious acid 0.02 centig.
 Powdered iron } aa, 1 gramme.
 Sugar of milk }

To be made into twenty doses; one every four hours.

21st November: Feverishness altogether gone; she is getting better every hour; I prescribe roasted meats and quinine wine; also

Arsenious acid 0.1 centig.
 Powdered iron 0.2 grammes.

To be made into twelve doses; one three times a day before each meal.

25th: Improving; to continue same diet; quinine wine and iron powders.

26th December: At this period her health is good; there is slight œdema in the right leg; our patient is following her usual avocations, and I did not think it necessary to continue any more treatment.

Proceedings of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JAN. 23RD, 1866.

Dr. ALDERSON, F.R.S., President.

AN ACCOUNT OF AN ARTERIO-VEINUS CYST IN THE POPLITEAL NERVE; AMPUTATION; RECOVERY.

By C. H. MOORE, F.R.C.S.,
 SURGEON TO THE MIDDLESEX HOSPITAL.

A WOMAN, aged 31, received a blow with an iron pump-handle in the middle of the ham. In a fortnight a painless, movable swelling, of the size of a hazel nut, was found in the situation of the injury, and but for its distance from either hamstring would have been pronounced to be an enlarged bursa. In sixteen months' time the tumour had increased, and seemed partly solid, and she first felt pain, which was referred to the foot. Three months afterwards, and twice subsequently in the following three months, the swelling was punctured, and on each occasion a yellow fluid, tinged red, first escaped, and as it flowed gradually deepened in colour, and continued to issue freely as blood from an open vein. The tension of the swelling was but temporarily reduced by these operations, and it increased in size so as completely to fill the ham, and protrude backwards in two prominent lesser swellings. The pain in them and along the leg and foot, the exquisite tenderness of the tumour, and a peculiar sudden pang shooting to the foot, while the canula was held motionless in the tumour, showed the nerve to be in some way mixed up with the swelling. After putting on a tourniquet, Mr. Moore made an incision into the tumour. Serum, black clot, loose fibrin, and some small clusters of white corpuscles were dislodged, partly with the finger and partly with a copious rush of blood from a vein at some deep part of the large cavity which had been opened. This proved to be a thin cyst, with a shining interior membrane, expanded into alternate ridges and saeculi, and traversed, like an auricle or right ventricle, by many firm cords. It being impossible to dissect it out, and improper on account of the state of the woman's health to leave the sac to suppurate, Mr. Moore at once amputated the limb. The patient recovered. Upon examining the limb the disease was found to be a vast cyst within the popliteal nerve, shaped like a double cone, one continuous with the higher, and the other with the lower end of the nerve. The expanded and hypertrophied textures of the nerve constituted the cyst, and the cords passing through it and along its walls were disparted nerve-bundles. A large vein, having no valves between it and the popliteal vein, opened obliquely like the ureter, on the front of the cyst; and in the upper cone, where

alone firm lymph was collected, an artery equal in size to the superficialis volæ opened into the cyst. The disease thus proved to be an arterio-venous aneurism, but unlike those which are more commonly observed in the small size of its artery, in the possible fact of venous blood having sometimes regurgitated into it, and in the unruffled quiescence of its contents, which had even separated into their natural constituents, almost as when blood coagulates after its withdrawal from the living body.

Mr. GASCOYEN eulogized Mr. Moore's treatment of his case, and thought it preferable to tying the femoral artery. He related a case in which a patient suffered from bronchitis, and a tumour in the popliteal space, which was of an aneurismal character. He tied the femoral artery. The patient lived a year, and then died of heart-disease. The tumour in the popliteal space was found to be coated with the posterior tibial nerve, which completely encased it. The tumour was filled with coagula.

Mr. HOLMES COOTE was inclined to think, looking at all the circumstances of the case, that the tumour in Mr. Moore's case was of a malignant character. He had seen and heard of several cases in which a tumour, supposed to be a blood-cyst, turned out to be malignant.

A CASE OF MULTIPLE NEUROMATA AFFECTING THE NERVES BOTH WITHIN AND EXTERNAL TO THE SPINAL CANAL, SOME OF THE TUMOURS BEING OF A CYSTIC NATURE.

By SEPTIMUS W. SIBLEY, F.R.C.S.E.,
 LECTURER ON PATHOLOGICAL ANATOMY AT THE MIDDLESEX HOSPITAL.

This case was submitted to the Society as being a remarkable example of the cystic form of nerve-tumour, and as an illustration of the extraordinary multiplicity which is sometimes observed in this form of disease. The subject of the disease was a coach-painter, who died at the age of 45 in the Middlesex Hospital, under the care of Mr. Henry. The patient had enjoyed good health till seven years before his death, when he became less strong, but had no definite symptoms till four years ago, when the use of his lower extremities became impaired, and by degrees he lost all power of movement. He had also suffered from sloughing of the back. When admitted into the hospital, he had no power over the voluntary muscles of the lower half of the body, the legs being contracted and drawn up. He retained some power of motion over his upper extremities, being able to feed himself if his food were first cut up for him. Cutaneous sensibility was quite absent in the lower extremities; but he was able to feel to a certain extent with his hands. The urine and the faeces were passed involuntarily. A large tumour was observed below the elbow, and another below Poupert's ligament on the left side. He died after he had been in the hospital a month.

At the post-mortem examination there was no disease of the viscera of the chest or abdomen. The brain and the cranial nerves were healthy. On opening the spinal canal a number of tumours were observed connected with the nerves within the membranes of the cord. In the cervical region there were several tumours, and the largest of these (about the size of a large nut) had pressed upon the spinal cord, which at this point was extremely constricted and softened. There were also many neuromata in connexion with the nerves in the lower part of the cord. In some places these were so numerous as to present the appearance of beads strung on a thread. The large tumour which was observed during life below Poupert's ligament was found to be connected with the anterior crural nerve. It was enclosed in a fibrous capsule, and on section presented the appearance of a fibro-cellular tumour interspersed with cysts. These cysts were of various sizes, the largest being about the size of an egg, and partly filled with imperfectly organised blood clots. A second smaller cyst was filled with gelatinous material. The remaining small cysts were filled with clear serous fluid.

SURGICAL SOCIETY OF IRELAND—JAN. 19.

Dr. WILMOT, President of the College, in the Chair.

MR. PORTER read the following paper
ON LITHOTRITY

The specimens I have the honour to lay before the Society are two urinary calculi, which I crushed during the last twelve months. They are both lithate in composition; one was three-quarters of an inch in the diameter in which I caught it—the patient 68 years of age—and it was removed in eight sittings. The second was in a man, aged 74; its size in the diameter seized 9-16ths of an inch, and removed in four sittings. I have much pleasure in exhibiting them under your presidency this evening, as I am aware that lithotripsy is an operation to which you have paid great attention, and on which, Sir, you have ably written.

I am also induced to show them, because I believe I am right in stating (and if not, I shall feel obliged by any member correcting me) that *disintegrated* stones have not been often, if ever, brought before our meetings. Surgeons in this country have not contributed the accounts of their cases of this operation and the after-treatment of their patients as frequently as they might have done, and thus we must acknowledge ourselves indebted chiefly to English and Continental brethren for practical information concerning this important operative procedure.

Little more than forty years ago lithotripsy, I may say, was in its infancy. Now, after the test of years, and having outlived the attacks and objections of those who consider lithotomy the rule and lithotripsy as the exception, it, in the present day, stands out as one of the greatest improvements in modern surgery, and is likely, in almost every instance, to supersede the formidable and dangerous operation of cutting for the stone. Sir William Ferguson, a surgeon of acknowledged skill as a scientific and daring operator, and whose labours in behalf of British surgery have lately been (with universal professional approbation) rewarded, has recently published the following all-important results of his operations for stone. He says:—"I can give a list of lithotomy and lithotripsy *conjoined*, which, as far as I know, has fallen to the lot of few other men in Britain. I have personally, by operations, treated 271 cases, 162 by *lithotomy*, and 109 by *lithotripsy*; and I have now to state that which I look upon as of high interest in the modern history of surgery. Of these 271 cases 217 were adults; 110 have been treated by lithotomy, and of that number 33 have died; 109 have been treated by lithotripsy, and of that number 12 died!" He also adds:—"In my own hands, whatever clumsiness or skill they may possess, the operation of lithotripsy has been considerably more successful in regard to saving life than lithotomy."

Now, Sir, that this operation is established as one of such great importance, and particularly as (I am proud to say it) some of the greatest improvements in the instruments requisite for its performance were devised by Irishmen—L'Estrange and Oldham—I trust that surgeons in this country may more frequently give us the results of their experience.

Mr. Porter proceeded to say that the detritus which he had the honour of laying before the Society exemplified one or two points connected with the operation. There were some large fragments in it, so large that one could hardly believe it possible that they could pass through the urethra without check, or of such shape that it was difficult to conceive how they could pass without causing a great deal of irritation and being stopped in the way. He had brought with him two of the most powerful of Weiss's lithotrites improved by Mr. Thompson of London; the improvement being the cylindrical handle, by which the surgeon takes hold of the instrument, and the manner in which, by a touch of the finger, he could put the screw into action. One of these instruments was particularly adapted for crushing fragments, being so constructed that

it could not pinch the bladder. The male blade was so small that should it unfortunately break it can be removed without cutting. It was so powerful that any lithic stone could be broken with it without taking the fenestrated one. Weiss's was a clumsy instrument to manage, but this one could be managed like a catheter or bougie in the bladder. There was another instrument he wished to show, invented by Mr. Cliver, for washing out detritus from the bladder after the operation of lithotripsy. Mr. Cliver's plan was to pass in a catheter. He then has an india-rubber bag with a bottle attached to it filled with tepid water, attached to the catheter. By pressing the bag the water is injected into the bladder, and by removing the pressure the water comes back again, and as the little particles of stone passed from the urethra, they are deposited in the bottle and remain there. He (Mr. Porter) used this instrument in a case where the calculus was composed of oxalate of lime. The patient had a weak bladder, and none came through for some days; but by the means of this instrument he removed three pieces of considerable size without difficulty, and he had seen Mr. Adams do the same, and remove a large quantity of detritus which was safely caught and lodged in the little bottle.

In reply to the President, Mr. Porter said, that when the calculus was composed of oxalate of lime he used the larger instrument, but in a case of lithic acid it was unnecessary to use the fenestrated one. The instrument which he now exhibited would break any stone.

Mr. STAPLETON observed that it was to Civiale the profession was indebted for this instrument.

Mr. FLEMING said that Mr. Thompson's work was published in 1863 and before that the outline of this instrument appeared in the *Lancet*. It was to Civiale they were indebted for it, and the only thing done by Mr. Thompson was the adding of a handle.

Mr. L'ESTRANGE said he had known that Mr. Porter was to bring forward this subject he would have brought with him some very large specimens of detritus removed by his (Mr. L'Estrange's) instrument by the late Dr. Hutton, who was the first to introduce to any extent the breaking of stone by the screw.

EDINBURGH MEDICO-CHIRURGICAL
SOCIETY.

WEDNESDAY, 7TH FEBRUARY, 1866.

Dr. MOIR, President, in the Chair.

PROFESSOR SPENCE showed a tumour which he had removed from the upper jaw of a female, which was of a suspicious character, and which he had thought it safe to extirpate; also a tumour of the lower jaw which had projected backwards into the throat, rendering deglutition somewhat difficult. A drawing of the face of the first patient by Dr. John Smith was also exhibited.

Dr. WATSON showed the entire head of a man, who had died while in a state of intoxication, and in the substance of whose brain a clot of blood was discovered.

Dr. WATSON likewise showed the portions of bones removed in two cases of excision of the knee-joint, one primary, the other secondary; also the bones removed from the wrist of a patient on whom he had operated according to Lister's plan.

Mr. ANNANDALE exhibited the bones of the forearm of a patient which had been fractured by being caught between the buffers of two railway waggons. When Mr. Annandale saw the patient he found there was also a dislocation of the head of the humerus and gangrene of the limb, which necessitated amputation at the shoulder-joint. The cause of the gangrene was not very apparent, unless, perhaps, it might have been produced by pressure of the dislocated humerus on the axillary artery. The man died. Mr. Annandale also showed several calculi he had removed from the urethra.

Dr. JOHN SMITH then read a paper upon Chloroform,

which excited a lively discussion amongst the members, in which Drs Gillespie, A. Inglis, Andrew Wood, Argyle, Robertson, Dycer, Messrs. Spence and Annandale, took part.

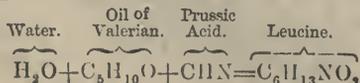

Dr. SANDERS read a paper on Aphasia, and showed a patient who was suffering from this form of paralysis.

Reviews.

DR. ODLING'S LECTURES ON ANIMAL CHEMISTRY.

THESE Lectures, which were originally delivered by Dr. Odling at the Royal College of Physicians of London during the past spring, have been recently published in the *Chemical News*, and are, we understand, shortly to appear in the form of an independent volume. Those who had not the opportunity of hearing these Lectures are under a deep obligation to the Editor of the *Chemical News* for the comparatively wide circulation which he has thus given to a Course of Lectures which deserve to be most carefully read by all who take an interest in the composition of the various structures of which the animal body is made up, and in the study of the varied series of action, healthy and morbid, which are continually taking place in the living organism.

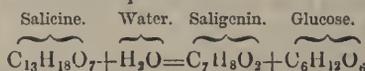

In the first Lecture, Dr. Odling, after a few introductory remarks, points out the difference between statical and dynamical chemistry, the former being "concerned only with the composition of parts, with the different kinds of matter of which all tissues and fluids of the body are composed," while the latter deal with "the change of composition undergone by various parts from nutrition." While chemistry treats of the composition of bodies, it has special reference to their changes in composition, and, as the Lecturer well observes, "the chemistry of every animal tissue, of a piece of muscle for instance, no less than of a piece of iron, has reference to its origin and metamorphoses. The chemist looks equally to its past and its future—to the pabulum from which it was formed and to the products with which it is ever changing." The recent advances in the chemistry of the tissue products, such as urea, taurine, kreatine, leucine, tyrosine, &c., are then noticed, and leucine and taurine are selected as striking examples of complex animal products whose intimate constitution is now so well understood that they can actually be built up by the chemist in his laboratory without having any recourse whatever to organic nature. Thus leucine, a white crystalline body whose composition is represented by this formula, $C_6H_{13}NO_2$ (the atomic weights adopted by Dr. Odling being those of the unitary system, O being 16 instead of 8, S being 32 instead of 16, and C being 12 instead of 6), are what occurs naturally as a product of the use and consequent waste of the pancreas, spleen, and other glandular tissues, may not only be made artificially in the laboratory by the breaking up of muscle, horn, hair, &c., but may be produced, quite independently of animal life, by the combination with one another of water, essential oil of valerian and prussic acid, according to the formula—

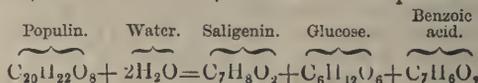

Similarly, taurine which exists in conjunction with cholic acid in the bile, and has been found in glandular

tissues, and whose composition is represented by the formula, $C_2H_7NSO_3$, may be artificially formed from sulphuric acid, alcohol, and ammonia, each of which again is capable of being produced from its constituent elements. This illustration was followed by an account and exposition of the theory of types, the recognition of which "with the establishment of their nature and mutual relationship, constitutes the great chemical advance of the last dozen years," and the proper understanding of which, "enables us to give at once a more or less satisfactory interpretation of even the most recondite discoveries of modern organic chemistry," and the Lecture concludes with various examples selected from organic compounds, showing the wide applicability of the type theory, and proving that by its means we are capable of associating with one another the most diverse bodies, and establishing between them the same simple relations which subsist between the three primary types—viz., hydrochloric acid, water, and ammonia.

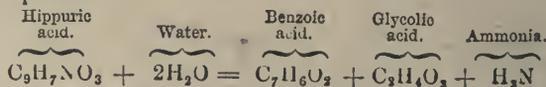

The second Lecture is mainly devoted to prove that the complex character of many organic bodies is more apparent than real, and that most of them may be resolved into comparatively simple molecules, which are capable of being distributed into certain well-defined groups and series. Thus salicine, the crystallisable bitter principle of willow bark, by an absorption of water may be made to break up with the less complex bodies, saligenin and glucose, as shown in the equations:—

While under similar circumstances, Populin obtained from the leaves and bark of the poplar, breaks up with saligerine, glucose, and benzoic acid, as shown in the equation:—

It must not be inferred from the former of these equations that either saligenin or glucose, as such, pre-exists in salicine; all that can be inferred is, that salicine "contains, in a state of combination, a residue of saligenin and a residue of glucose, which residues are, as it were, ever on the alert to take up water, and so produce the separate and distinct molecules of saligenin and glucose respectively," and the above remark applies equally to populin. The animal product, hippuric acid, is similarly but much more fully discussed. A molecule of this acid is represented by the complex formula $C_9H_9NO_3$, is now known to consist of a residue of benzoic acid, a residue of glycolic acid, and a residue of ammonia, united together in a particular manner, these residues becoming complete molecules by the absorption of water, as shown by the equation:—

Amongst the most important points discussed in the third and fourth Lectures are, the tendency of oxidation to produce molecules with fewer, and fewer carbon and hydrogen atoms, the first product being carbonic anhydride CO_2 , and water H_2O , evidence that the natural synthesis of organic compounds is attended by deoxidation; the formation of vegetable tissue and secretion from the deoxidation of carbonic anhydride and water; the formation of nitrogenized tissues; historical sketch of organic synthesis; the convertibility of heat and mo-

tion; all terrestrial force traceable to the sun; the accumulation of solar force by vegetable organisms, and its dissipation by animal organisms; various illustrations of the processes of synthetic chemistry; and, finally, the question of the possible artificial manufacture of food. regarding which, as might be expected, he does not speak very hopefully.

The fifth and sixth Lectures treat of the oxidation of muscular tissue; the economy of muscle as a motive exponent of combustion; the reciprocity of heat and motion in muscular action; the artificial oxidation of muscle; the constitution of the acids obtained by muscle oxidation; uric acid, including its chemical examination, and the classification of its products; and the last Lecture (the sixth) concludes with some excellent remarks upon the influence exerted on tissue metamorphosis by those chemical agents which are usually included in the class of alterative medicines. In composing these Lectures, Dr Odling has done good service, both to the chemist and the physician, and we shall be glad to see this course developed, when the author has sufficient leisure, into a systematic work on "Animal Chemistry."

ON THE USE OF THE NITRATE OF SILVER IN THE TREATMENT OF INFLAMMATION, WOUNDS, AND ULCERS. By JOHN HIGGINSBOTTOM, F.R.S. London: John Churchill and Sons.

HIGGINSBOTTOM "On Nitrate of Silver" is now pretty well known to the British public, and although his name is identified with the subject almost as of one riding his hobby, yet the author deserves our best thanks for the way in which he first drew attention to the subject in 1820. In the treatment of deep-seated inflammations and erysipelas, the use of the nitrate is attended often by the best effects. We hardly are inclined to agree with the writer that when applied in the solid form to a raw surface it does not act as a caustic, but that it forms a coating over the surface which protects the part from the action of the atmosphere, that unfortunate element to which we are so ready to attribute any mischief, that we cannot explain ourselves. In fine, it appears there is not a malady almost under the sun for which the salt cannot be prescribed with advantage. The directions are very clear and explicit, the book is nicely brought out, and it has been already received as a text book by the profession.

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 14, 1866.

QUACK DOCTORS AND QUACK LAWYERS IN COURT.

In our last week's number we printed some remarks lately addressed by the Judge sitting at the Old Bailey, to a prisoner convicted of receiving money under false pretences, the pretence being that he was an attorney. It appears that the accused person was in all respects, except the charge on which he was tried, a perfectly respectable man, and his crime was that he represented himself as an attorney, and in that capacity

assisted the prosecutor in asserting some claims in Chancery. For these services he received the sum of about £47, a very moderate amount in comparison with the charges usually made by attorneys in conducting Chancery, or indeed any other law business, but he was actually arraigned, on technical grounds, for receiving only £10.

Now Medical men knowing how their own Profession is treated in the law courts, might naturally ask what offence the prisoner had committed? It was proved, indeed, that he had represented himself as an attorney, and had also, we believe, placed his name on a brass plate; and, moreover, that he had received £47 for conducting some law business. But in this free country where, we are told, every one has a right to employ a quack doctor, why may he not employ a quack lawyer? and why is the latter to be punished, while the former escapes? In the particular case to which we now refer, the prosecutor must have been deceived with his eyes open, for it was perfectly easy for him to consult the Law List and ascertain whether the prisoner was really an attorney or not. But the punishment inflicted on the quack lawyer, although said to be a mitigated one by the presiding Judge, was one tantamount to utter ruin, and consisted of imprisonment and hard labour for four months, the forfeiture of his position in society (he was a parish clerk), and the misery and degradation of a wife and a large family.

Now the quack doctor has his name on a brass plate, and he advertises in the *Daily Telegraph* and the *Morning Star*, and a host of other journals; he keeps an expensive house, and he, perhaps, rides in the park in a carriage and pair, himself covered with rings and watch-chains, and his wife and daughters bedizened with jewels. He is not only an ignorant man, but a rogue into the bargain, and not content with such paltry sums as £10 or £40, as in the case of the unfortunate parish clerk, he pockets his gains by the hundreds and thousands, often involving men of expectations in absolute ruin, and draining many a poor clerk of his last shilling to meet his extortionate demands. But how does the law deal with this man? Why he is absolutely protected by the law in his iniquitous career, and he sets the Medical Council and the Medical Colleges and Halls at utter defiance. If an attempt is made to summon him before the legal tribunals, it is found that he has half a dozen names, or that he is one of a gang of people who all go by the same name, and this circumstance, instead of adding to his iniquity, is cunningly converted into a means of evading responsibility. Supposing him to be actually caught within the meshes of the law, his escape is perfectly easy, for he merely pleads that he is *not* qualified as a Medical man, and therefore is not amenable to the powers of justice. Nay, more, if a quack doctor, herbalist, bone-setter, or other member of the same tribe, should cause the death of a person by the grossest ignorance, he would be acquitted, *because he is a quack*, while a regular and

honourable practitioner, who may have had an unfortunate case, is liable to the severest punishment.

This subject is of so much importance at the present moment, when it is essential to urge a reform of the present laws relating to the Medical Profession, that we make no apology for thus pressing into notice the monstrous anomalies under which we labour, and we place, for the sake of greater distinctness, in parallel columns, passages from the actual address delivered by the Judge to the convicted quack lawyer, and another address, which might be delivered by the same Judge to a quack doctor. The latter address is of course imaginary, but it represents in true colours the prevailing state of the law in reference to the irregular practice of Medicine.

JUDGE TO QUACK LAWYER.

John Black, you have been convicted of the offence of obtaining money under false pretences. You represented yourself to be an attorney, and in that capacity you received from the prosecutor the sum of £47 for pretending to conduct a Chancery suit.

There is no doubt that the prosecutor was exceedingly wrong in placing his case in the hands of a non-professional man.

The prosecutor was dragged by you through a long course of expensive litigation, but his folly in intrusting himself to your hands, instead of decreasing, rather increases your offence.

You seem to have got on the door of your office a brass plate on which is engraved the name of a solicitor, and I hope that this case will have the effect of calling the attention of the Law Association to a practice by which unwary clients are deceived.

This is a direct case of obtaining money under false pretence, and although you have hitherto held a respectable position, and have a wife and a large family, who will be ruined by your sentence, you are hereby imprisoned and kept to hard labour for four months, and this is a very lenient judgment.

Do we exaggerate the case as it stands between quackery in the Law and quackery in Medicine, and the relative estimation in which each is held by the legal tribunals?

JUDGE TO QUACK DOCTOR.

John White, you have been acquitted of the offence of obtaining money under false pretences. You represented yourself to be a Doctor of Medicine, and in that capacity you received from the prosecutor the sum of £500.

There is no doubt that the prosecutor was perfectly right in placing his case in the hands of a quack doctor, i. e. he thought proper to do so, because England is a free country, and a man may do as he pleases in this respect.

The prosecutor was dragged by you through a long, useless, and injurious course of medication, but his folly in intrusting himself to your hands is very properly visited upon himself, and it exonerates you from all legal responsibility.

You have on your door a brass plate on which is engraved a name and a title to which you have no legal right; but if the unwary patients are deceived by such devices, that is their own affair and they deserve, and will receive no protection from the law.

This may be said by some moralists to be a case of obtaining money under false pretences, but the law says otherwise, and although you are a man of disreputable character, assuming fictitious names for the purpose of fraud, living upon the plunder of the unwary, and practising a profession for which you have no qualification, you have very properly been acquitted by a British jury, as there is really no case against you.

SHOULD THE MEDICAL PROFESSION BE REPRESENTED IN PARLIAMENT?

The object of reform in Parliament is to represent all classes and interests, so that when a question is discussed some members present may thoroughly understand it, and bring forward their practical knowledge for the benefit of their own constituents and the nation at large. Mr. BRIGHT and his party are seeking such a reform as shall represent one class, and one only; they wish for an overwhelming preponderance of members, because they think that these members will support their private views and bring them into office. Should they succeed they will place England in the position of America, where the only ruler is a tyrant majority, and where property is insecure, as it may be invaded by the multitude. Now, we always advocate Reform, if by the word is intended a real improvement. It is most desirable that every interest should be represented, and we can show one most important section of our community which has as yet been passed over—we mean the Medical Profession. The Army, the Navy, and the Law, send many Members to the House of Commons. An eminent lawyer is generally elected where a local member does not present himself, and these three professions are the great source of the new blood infused into the House of Lords. Judges, ex-Judges, and Bishops, form an integral part of the Upper House. The Lords cannot proceed without them; but no Physician has ever been made a Peer. GEORGE IV. was anxious to have raised SIR HENRY HALFORD to the Peerage, but could not find a precedent. The Clergy are represented in the House of Commons, though (perhaps unfairly) excluded from it. The three Universities give them great weight, and glebe lands and rent charges constitute freeholds.

Very few members of the Medical Profession are elected to seats in the Lower House; these are chosen from political motives rather than professional experience. They are usually men who have given up their practice, and they are certainly not the most eminent in their profession.

While no body of men is so ill represented, there are no men who so well represent all classes of the community. They are pre-eminently the friends of the poor, they are conversant with social questions, the working of charities, and the various attempts for promoting public good. Above all, they have a knowledge of sanitary measures, of disease, and remedies in every form, and what unprofessional men learn from reading and conversation, they understand by experience.

The rinderpest now occupies our thoughts. Much legislation for good or for evil may be expected. A Committee of the House of Commons will examine and report; Physicians, Surgeons, Cattle Doctors of every class will be summoned as witnesses, but no first-rate professional man will be judge in the case. How much more efficient legislation might we expect, if one or two men of first-rate medical standing could speak and

explain a report to the non-professional members of the House of Commons.

The consequence of this state of neglect of Medical interests is apparent. No profession is at this moment in such confusion. The writer of this article has been asked to advise as to the best way of entering the Medical Profession. He found himself quite at a loss, and believing it was a subject which he ought to understand, he read carefully the evidence laid before Parliament. At the end of his studies he only knew less than before. A vast conflict of vested interests—Physicians, Surgeons, private Medical Schools, Colleges in England, Ireland, and Scotland—some claiming a monopoly, others professing to have rights, and contradicting the assertions of the rest. The whole system appeared to be one of hopeless confusion, so that no man could be expected to give or form an opinion but a man who had known by experience the value of conflicting claims, and who could say I can show the reason why one young man has succeeded and another has failed.

At that time the question of Medical Education came before Parliament. The writer accompanied a Member of Parliament to the houses of the most eminent men in the profession. Our friend said, "I cannot understand these questions; but I have considered them and taken down the views of Sir PHILIP CRAMPTON and many of our first practitioners, and I shall endeavour to form my own opinion." How different would it have been had Sir PHILIP been a Member of Parliament.

When the question of the Incumbered Estates Court was first proposed, we were present at the debate. A Member stood up on the back benches on the Opposition side of the House, he spoke very indistinctly, and seemed to labour under some impediment. His words came with great difficulty, and, since the days of Lord ALTHORP, the House could scarcely have had a less pleasing speaker; yet every eye was turned towards him, every ear was open. We inquired who he was, and were told that is Mr. —, he is considered one of the first legal opinions at the bar. It was evident that the whole House of Commons were eager to hear what a great lawyer had to say on a great legal change. Sir PHILIP CRAMPTON stood as high in his profession, and certainly would have spoken much better. Now, to propose a remedy. Let any change of representation include a few clauses for incorporating the Medical and Surgical Colleges, and giving them representatives, say two each to the three kingdoms. In other words, let a certain defined qualification entitle the holder to a vote for the representative of his College.

We have a precedent in the three Universities, which are the only remnant of corporate representation which Lord JOHN RUSSELL's reform has left us. They give the three best seats in the Lower House, and have been called House of Commons' Peerages.

Let the nation now try the same system with a Profession unrepresented. The Ministry are anxious to bring in a popular measure of Reform. Here would be

one universally popular. Every man would like to see his Medical attendant gain a privilege which would not be given at the expense of any class. It would not make the Government more democratic; it would not increase the power of the aristocracy; it would be simply an act of justice to men highly educated and badly paid, who labour for all, and yet usurp the rights of none. We constantly hear complaints of the treatment of practitioners in the country, that their social position is too low, and their labour too great. Now a slight political privilege would raise their position, and if any real injustice were done to them by the law, their representatives could always speak in their favour.

We hope by raising the question to stimulate our Medical friends to exertion. We believe if the question were properly discussed, public opinion would be strongly in favour of giving representatives to the Medical Colleges.

QUACKERY UNDER EDITORIAL SANCTION.

CERTAIN of our Dublin newspapers, the *Irish Times* leading the way, have within the last month permitted their columns to be used for purposes, which, we think, cannot be too strongly condemned, and they have done so in a manner which lays their editors open either to the charge of great carelessness or else of venality. From time to time the public have been enlightened through the pages of these journals by pseudo-medical letters from a member of the profession, who well knows what a command of the uninitiated public the latitude so easily accorded gives him. These communications profess to be intended to instruct every-day readers on coughs and colds, bronchitis and phthisis, and uniformly dwell with pathetic fervour on the fearful results which must accrue to misguided patients who permit as much as Ahem! without seeking a safeguard against consumption and pneumonia from the talented monitor to whom they are indebted for their very unnecessary alarm. We are, of course, not so foolish as to bandy words with the person who resorts to this means of making practice, or dwell on the impropriety and disrepute of the course which he pursues, and which we are quite sure he knows as well as we do ourselves; but we must point out to the conductors of the journals which admit these letters the injury they are doing, not only to their readers, but their own character, in doing so. It should be remembered that letters on a professional subject are not like ordinary newspaper correspondence which every reader can take to pieces for himself, and despise or admire according to his own judgment. The readers of a newspaper must accept without suspicion the facts and arguments of such communications on no other authority than the guarantee of the editor who endorses them by admitting them to his journal; and if he does so without proper consideration, or in the face of the knowledge of the suspicious source from which they emanate, he is simply filling his paper with what he may more than suspect to be false in fact, and most injurious to his

readers. The letters of which we complain are scientifically the poorest and most fallacious stuff which can be conceived—apparently an appropriation of the letters of the notorious Dr HUNTER, and a gross exaggeration of every-day ailments, but being backed by the official countenance of the Editor, they are read by the public as *epitomes* of wisdom and experience in thoracic affections. Such lucubrations were very properly put to their only use as advertisements in the London journals, and they should either appear as such in the Dublin papers or be refused insertion altogether.

DERMATOLOGY PUT TO TEST.

WE wonder very much what will be the next move in the drama of the cattle plague. Men, in keeping with the competitive "go" of the age, have rushed with hot haste into unguarded expressions and haphazard statements. We saw the inevitable end some time since, and called attention to the unbalancing of judgment so largely now-a-days produced by the disease *sensation*, which, prevalent as rinderpest, is quite as infectious and as sturdy in virulence and onward course. It has always been a grievance with our common profession that appeal is not more frequently made to our experience, in reference to any social or scientific matters about which the public may be at a loss, but upon which we may throw some light, in the same way that questions are referred to the various Academies in other countries for decision or elucidation; but it must be no surprise to us, so long as the practice of truckling to the public directly, through the organs of daily non-medical journalism, is so much in vogue. There are many causes which lead to this—the force of example; the eliqueness of our own press, and its panderings to *popularity*; the rapidly-advancing fusion of the *pure* and *general* practitioner, engendering the invention of novel means and ways to "hook" patients; for, say what we will, this is a circumstance which is exemplified in the doings of a large section of consulting men, and one much to be regretted, one, moreover, which falls hard upon the *mass* of our profession. The Chemist on the one hand, and the "Physician" on the other, encroach upon the rights of the General Practitioner more extensively than perhaps most are aware of. However, we have not been content to wait till the report of the Commission appeared. The correction of miscalculation and mal-observation might have been secured by discussion amongst the members, or dubious points illustrated by explanatory comments supplemented to the Report. No; Commissioners, workers for the Commission, one and all, fairly ran away, and whoever held the reins must now be much disgusted at the present "break down." Some of these gentlemen have figured themselves in the *Times*, possibly to their heart's content, but their behaviour, nevertheless, has in no way been calculated to enhance the respect of a shaky-faithed public—who only accept the recommendation of success—for Medicine and its art.

For a while we quite anticipate a lull, upon the principle that "after a storm comes a calm," and in the meantime the rinderpest will certainly increase. It is just possible, however, that the unbounded licence given to every novel hypothesis, and the "unlimited liability," so far as professional censure is concerned, may help towards the establishment of some fresh idea, to be hunted down ignominiously

like many predecessors; already it has been suggested by one that rinderpest is diphtheria, by another cholera. "*Parallèle entre le Choléra-Morbus et le Typhus Contagieux des Bêtes à Cornes*," is the title of a work by M. DECROIX. We have been anxiously looking forward for the issue of Professor Gamgee's work, from which we expect much good to result. It will be a thick octavo of 850 pages, and we understand that it will appear in a few days. We will just ask the question, has vaccination been fairly tried? Have not the majority of animals when vaccinated been under the possible influence of rinderpest poison?

But we have a special word to say about the skin eruption. No observant man can have failed to have noticed the glaring inconsistencies in the statements and descriptions, by equally good authorities in general matters, in reference to the eruption of cattle plague. Professor GAMGEE, Dr. SANDERSON, Dr. MURCHISON, and Dr. BRISTOWE, all differ in their written and recorded views. According to one it is *epithelial* degeneration, to another *sebaceous*, to another *pustular*; others again declare that it is *papular*, and some affirm it may be *vesicular*. Really there must be something radically wrong here, but the state of the whole subject of skin eruptions is one which is a disgrace to us English. The amount of clinical teaching in London is practically *nil*; there is the most delightful uncertainty and vagueness as to the nature of the very commonest elementary lesions; diagnosis is often unattempted, and more frequently erroneous; we have seen case after case of scabies mistaken for eczema, and the most common forms absolutely unrecognizable. Yet there is no lack of sufferers. Why there are four independent institutions at this moment in London; two of these, it is said, receive nearly a thousand a year each from the patients themselves, and the other two are largely supplied with a, plicants from all quarters, but none are *wholly free*. In the out-patients' department of the recognized hospitals cutaneous diseases have no definite position; they belong to anybody, Physician or Surgeon. As has been said by one of the most distinguished in the profession. "The majority of students leave the hospital without being able to recognize the most common diseases of the skin." It would be conducive to a better condition of things if the members of our various Examining Boards would take means to secure proficiency in matters dermatological. Just now, as has been pointed out, the doctrines of WILLAN and BATEMAN are silently and gradually being shelved and overridden by those of Continental authorities. We are disposed to believe that there are hidden truths of great significance in the doctrines of our countrymen, and those who are disposed to contest the innovations which would rob WILLAN of his due are placed utterly *hors de combat* from the want of opportunity and *matériel*. The principle of division of labour is acknowledged on all hands, and the sooner we devise some means by which the study of cutaneous medicine can be advanced the better; for the ignorance of elementary principles and erroneous observation in the recent matter of rinderpest eruption has been lamentable in the extreme—an instance only of the utter want of knowledge which obtains in everything connected with clinical observation in dermatology.

At a meeting of the trustees of Anderson's University, Glasgow, held in the hall of the Philosophical Society on the 29th January, Dr. McCall Anderson was unanimously appointed to the chair of Practice of Medicine.

REPORT OF THE DUBLIN CITY ANALYST.

THE first annual report issued by Dr. CAMERON since his appointment, was laid before the Corporation on the 15th ult., and we republish it below as fully as our limits permit:—

“35, Waterloo-place, Upper Leeson-street,
15th January, 1866.

“I beg to submit, for the consideration of the Sanitary Committee, the following summary of the duties which I performed during the year 1865, detailed reports of which have, from time to time, been laid before the committee:—

“ANALYSES.

“The following articles were analysed and reported upon:—

9 specimens of	Milk.
8 “ “ “ “ “ “	Bread.
6 “ “ “ “ “ “	Wine.
3 “ “ “ “ “ “	Tea.
2 “ “ “ “ “ “	Brandy.
1 “ “ “ “ “ “	Sugar.
1 “ “ “ “ “ “	Flour.
1 “ “ “ “ “ “	Coffee.
1 “ “ “ “ “ “	Water.

1 substance supposed to contain poison.
7 specimens of medicinal substances.

“Of these analyses, fourteen were performed for various public institutions within the municipal boundaries; the others were made for the information of private individuals. I have reason to believe that these analyses proved, in many instances, of great service to the institutions and persons for which and whom they were performed. Dr. Gordon, physician to the House of Industry Hospitals, assures me that the analyses of wine and tea which I made for those institutions were the means of greatly improving the quality of those articles, when subsequently supplied by the contractors. The only article which I found constantly adulterated was milk. I have never as yet examined a sample of this fluid which did not contain a large excess of water, fraudulently added, or that had not, which amounts to the same thing, been deprived of a portion of its cream. In some instances, I have found milk to be adulterated with its own weight of water. I am happy, however, in being able to state that, so far as my experience extends, water is the only substance employed in the sophistication of milk. There was one conviction for the sale of adulterated food during the year; this was in the case of the coffee above mentioned, which, though labelled a ‘mixture of coffee and chicory,’ was found to contain not a particle of the former.

“POISONOUS PICKLES.—With the view of ascertaining whether or not copper was present in green pickles, I examined twelve of those articles, obtained from different shops in the city. In seven of these samples I found copper. Although these pickles did not, in any instance, contain sufficient copper to warrant me in describing them as direct poisons, yet I feel justified in characterising them as being more or less unwholesome, especially if they be used frequently. Numberless accidents, many of them fatal, have occurred by the use of green-coloured confectionery. The colouring matter is usually a compound of copper and arsenic. Having visited most of the confectionery establishments in this city in quest of green confectionery, I am happy to say that I did not succeed in discovering any.

“ANALYSIS OF PUMP WATER.—At the suggestion of Dr. Mapother, I have undertaken the analysis of the water obtained from pumps to which the public are allowed free access. Last year I made thirteen analyses of these waters, and when a few others, now in course of performance, shall have been completed, the results of the investigation will be made public. In concluding the summary of the analyses which I have made during the year, I may state that the number amounted to sixty-five, as against sixty-four performed in 1864.

“SANITARY.—During the last year my services were at all times available to the medical officer of health. I regularly inspected the chemical factories; and I have every reason to believe that the suggestions which Dr. Mapother and I made to their proprietors have been acted upon, and have greatly lessened the evolution of offensive gases and vapours from these establishments. The directions which I framed for the chemical disinfection of dwelling-houses and stables, and which were approved of by the committee, were published in all of the Dublin and in many of the provincial newspapers, and I believe have been carried into effect by a great many persons.

“OPEN DRAINS.—At my suggestion an open sewer, near the Ringsend Basin, about 800 feet in length (and the channel through which flows the poisonous refuse matter from the gas works), has been closed over, to the great comfort of the inhabitants of the locality.

“INSPECTION OF MEAT.—I am always ready to assist the clerks of the markets in their inspection of meat, should any cases of difficulty arise. On one occasion I felt it my duty to condemn the whole carcass of a cow. Were public abattoirs established, I would be willing to make the scientific inspection of the flesh of animals exposed for sale a regular part of my duty as food analyst.

“THE VARTY WATER.—Agreeably to the directions of the Water-works Committee, I have made an elaborate series of experiments, with the view of ascertaining the action of the Varty water upon lead. This investigation has been completed, and the results laid before the Water-works Committee. In my report I recommended the use of an alloy for the manufacture of pipes, upon which I guaranteed that the Varty water would exercise no corrosive influence.

“CHARLES A. CAMERON.”

It appears evident from this report that the statute under which Dr. CAMERON was appointed has not effectually served the purpose for which it was created, in the protection of the public against adulterations of food drugs, not in the least from the absence of competency or activity on the part of the City Analyst, but on account of the indifference with which such sophistication is regarded

by the public, so long as it does not amount to absolute poison. Dr. CAMERON conducted in the entire year only thirty-four analyses at the instigation of individual consumers—a very small total for such a city as Dublin. The greater part of his time appears to have been occupied by sanitary inspections and self-imposed duties, which, though of themselves most valuable, are not at all those which were contemplated by the Act. The reason for this unsatisfactory result is not difficult to understand, and it is one which was fully anticipated when the Act came into force. By that statute Dr. CAMERON is simply empowered to investigate the purity of articles which may be brought to him for analysis, and as few persons will give themselves the trouble of making a formal statement on the subject, especially when they have not sufficient scientific knowledge to lead them to suspect the adulteration of a great many articles of their consumption, a great proportion of the articles of food pass without any inquiry whatever. It appears to us that the only remedy for this indifference is to make the public fully aware of the facilities for investigation which the Act affords, of which few persons know anything, and to warn them of the necessity for considering the purity of the articles which form their daily food.

PROVINCIAL INTELLIGENCE.

BELFAST.

[FROM OUR OWN CORRESPONDENT.]

BELFAST, Jan. 12, 1866.

In my last letter, which is now of rather ancient date, I mentioned that we would soon have a large addition to our General Hospital, in the shape of a new wing about to be erected by the generosity of John Charters, Esq., one of our merchants. The new building is only now finished, and is not yet occupied by patients. It contains two wards, each 57 feet long, 25 feet wide, and 16 feet high, lighted by 12 large windows, which are glazed with plate glass, two panes in each window. This increases wonderfully the external effect of the building, and is, of course, a most desirable thing, for many reasons, for the patients inside. The windows are hung in a peculiar manner, the upper sash working on swivel joints placed near the bottom, so as to allow it to open inwards at the top in a sloping position, thus permitting a large volume of air to pass in without exposing the patients to the annoyance of a down-draught falling directly upon their heads. The lower sash is hung in the usual way. The plan is similar to one adopted in King's College Hospital, London, and it is, I understand, about to be introduced into other hospitals. The wards look very handsome, being coated with Parian cement. They are ventilated on the Barrack Hospital system, which is very complete and efficient. The nurses' room looks into the wards by means of a small window, while the bath-rooms, water-closets, and lavatories, are separated from them by a broad staircase, which will completely prevent contamination from that source. There will be beds for 28 patients in the building, with a cubic space of 1500 feet for each person.

By the way, a rather amusing incident took place the other day in connexion with the completion of our new hospital wing. A homœopathic practitioner in town, formerly of Dublin or its neighbourhood, where, perhaps, he found the more legitimate practice of his profession less remunera-

tive than he desired, preferred a request to the Hospital Board, which was certainly rather modest. He wrote to the Board a lengthy *ad captandum* letter, in which he begs that, as the additional hospital accommodation, now completed, will probably be more than sufficient for present purposes, one or two wards may be placed at his disposal for the treatment of acute diseases of children. And, he goes on to state, it is an admitted and well ascertained fact, that the percentage of deaths from acute diseases of children, treated homœopathically, is very much under one-half the number that perish under the allopathic system. Actuated alone by a sense of public duty he requests the hospital authorities to give him two wards, containing beds for 50 children, in which case he will generously give his services gratuitously for one year. Only a wish, he adds, to mitigate the severity of childrens' diseases and save human life, and also to extend the knowledge of the truth, could induce him to undertake more responsibility than his present practice entails, which he takes care to tell us, is amongst the better and educated classes.

Now, it happens to be quite untrue that there will be more accommodation in the hospital, even with our present accession, than what will be required. The very contrary is the fact. But I dare say our homœopathic friend thought that Mr. Charters had, at great expense, built a new wing to the hospital with the knowledge that the wants of the institution did not demand it. With regard to the well-known and admitted fact that the mortality among children treated homœopathically is much under one-half what it is when they are treated allopathically, I can only say I did not know it before, and I do not feel inclined to admit it now, without some more trustworthy evidence being adduced in support of the statement than the mere unsupported assertion of a homœopathic practitioner.

Homœopathy is, in my opinion, a fanciful and fashionable delusion, whose chief supporters will be found amongst those credulous enough to believe the unlimited assertions of its professors, or those whose ignorance, both of scientific medicine and scientific principles, disqualifies them from forming any just opinion upon the subject.

Homœopathy will continue successful as long as the public continue to be gulled by the unscrupulous assertions of its professors. No scientific physician would make exact and positive statements about so complicated an organism as the human frame, or the effects of disease upon it. He can only give an approximation to the truth. But, where angels fear to tread, creatures of a different mould feel no hesitation in stepping in. The homœopathist is not in the least afraid to make the most unhesitating and positive statements. If these be sincerely made, one is compelled to form a very poor estimate of the capacity of the person who makes them; if, on the other hand, he does not believe in the faith he professes, the moral and mental degradation of the professor of homœopathy may best be left undescribed. In this instance the Board at once refused the very *gratuitous* offer that had been made to them.

I have not yet seen the returns showing the number of students attending the various Dublin hospitals; but I dare say, none of them much exceed the number on our hospital roll-book, which is 104, while there are upwards of 150 medical students at Queen's College.

At the College, great improvements are taking place in the accommodation provided for the medical faculty. The

dissecting-rooms have been greatly increased in size, and a large lecture-room for the medical professors in connexion with an extensive anatomical museum-room are both in course of erection.

A very large and influential meeting of the graduates of Queen's University was held here a short time since to protest against the contemplated affiliation of the Catholic with the Queen's University, thereby associating two institutions utterly dissimilar, and antagonistic in character and tendency, and wholly subverting the basis upon which the Queen's Colleges were established—namely, that of united education in Ireland. I believe that there are very few, indeed, of the graduates of Queen's University, be their religion Catholic or Protestant, who would see without feelings of the deepest regret the abandonment of that principle, the great advantage of which they have experienced in their own persons.

NOTES ON THE CURRENT TOPICS OF THE WEEK.

THE TRICHINA DISEASE.

OUR contemporary, the *Pall Mall Gazette*, which is generally pretty well informed in medical matters, has lately put forward some statements in reference to the trichina disease, which are not quite accurate, and are calculated needlessly to alarm the British public. It is stated that this disease, which undoubtedly exists in some parts of Germany, has made its appearance in this country, the only fact in support of such a statement being that a week or two ago the body of a man, who died from an accident, was examined in Guy's Hospital, and the whole of the muscles were found infested by the parasite. But the man did not die of the disease, which, so far as is known, does not exist to any extent in Great Britain. It is a curious coincidence that the first description of the *trichina spiralis* in this, or we believe any other country, was given by Professor Owen, from a specimen found in the dissecting-room of St. Bartholomew's Hospital, but the priority of the discovery belongs to Mr. Hilton of Guy's Hospital, who described the muscle infested by the worm as he saw it in a subject in the dissecting-room of the latter institution. The disease has appeared in an epidemic form, as far as we are aware, only in Germany, and it is attributed, and we believe with good reason, to the custom among the lower classes of eating ill-cooked pork.

PARLIAMENT AND THE CATTLE PLAGUE.

THE topic which has hitherto occupied the attention of both Houses of Parliament, almost to the exclusion of any other subject, has been the cattle plague. There are many reasons, political and otherwise, to account for this circumstance. In the first place, the Government of a country is always visited with reproaches whenever any misfortune befalls the nation, although the visitation may be beyond human control; and in the present instance, the Ministry being under a new head, and confronted by a powerful, though not numerically superior, opposition, every topic likely to damage the party in power is eagerly seized upon. But there is another and a still stronger reason for the great interest manifested in this question by the British Legislature—namely, that the enormous losses experienced by the cattle growers are beginning to tell most seriously upon the revenues of the agricultural Lords

and Commoners, whose incomes will be very materially impaired if the present mortality should go on increasing as it has lately done. For ourselves we desire to range ourselves neither among the Ministerialists nor the Conservatives, but in the interests of Medical science we join in the condemnation which has been passed by Members on both sides of the Houses of Parliament, upon the dilatory and vacillating conduct of the present Government in its dealing with the cattle plague. The authorities were made fully aware of the dangerous nature of the disease by the Commission appointed last autumn, and yet no decisive steps were taken, and the consequence is, that the infection has now spread over so wide an area that all efforts to arrest it must be infinitely less successful than if they had been adopted at the commencement of the outbreak. Instead of adopting such vigorous measures of repression as the occasion urgently demanded, valuable time was wasted in silly attempts to cure the disease by administering infinitesimal globules to the infected cattle, a course just as absurd in the attempt as of the philosophers of Lupaia to extract sunbeams from cucumbers. To this folly, and indeed to the folly of attempting to cure the disease by any other drug-medication, the Commission lent no countenance, but energetically recommended a policy of prevention. This advice the Government declined to adopt, and thus the disease has spread to such an alarming extent as almost to threaten the nation with the horrors of famine. We conceive, therefore, that the Government is justly held up to blame for neglecting the warnings of science, and thus allowing an enemy to gain possession of our territories, who might have been expelled on his first invasion, if the responsible Ministers had done their duty.

THE CANDIDATES FOR THE LICENCES OF SCOTCH COLLEGES.

It is worth while to call attention to the list of the gentlemen who obtained their qualification to practise last week in Edinburgh, which will be found in another part of our issue to-day. It will be perceived that fourteen candidates passed their final examination for the Double Diploma, and five their "Primary." The nationality of these gentlemen presents the peculiarity, that while no less than eleven out of the fourteen were Irish students, only four were Scotch, the rest being two foreigners and one Welshman. Of the five gentlemen who passed their primary examination, two were Irish, one English, and two Scotch. We recommend to the investigation of the Medical Council the problem as to why Scotchmen should constitute less than one-third of the Candidate Licentiates of their own Colleges, and that Irishmen should almost supply the other two-thirds. It is perfectly manifest that there must be some attraction to the Scotch licensing bodies comparatively to that afforded by Irish Colleges, and until the Medical Council can bring their official comprehension to see the causes which operate to this result, and which every teacher in the United Kingdom has for years fully recognized, we can hardly ask the Irish or English Colleges to maintain a high standard of qualification in their examinations.

THE cattle plague is committing fearful ravages in the Principalities. 315 oxen and 550 buffaloes have been carried off in the district of Varna. In the district of Rustchuk the mortality is estimated at 5064 oxen and cows, 525 buffaloes, 9986 sheep and goats, 224 pigs.

RETROSPECT OF THE JOURNALS.

IN a leader the *British Medical Journal* refers to a paper in the new number of "Guy's Hospital Reports" on the treatment of Rheumatic Fever with mint water. It will be at once observed that the administration of the mint was but a cloak under which the disease was treated without drugs. The astounding fact is now, after a lapse of years, again forced upon us, that in this as in many other acute diseases our treatment is as futile and inefficacious as it was twenty years ago. We were always inclined to agree with the aphorism, that there was only one cure for acute rheumatism—namely, six weeks.

Dr. Gall's undoubted conclusions, drawn from these cases, are: that the drug treatment of acute rheumatism, *cateris paribus*, is no better than no treatment at all; that cases treated without drugs do as well in all respects as cases treated with drugs; and that, therefore, too much importance is attached to the use of drugs in those cases of acute disease which have a natural tendency to recovery. In a future number of "Guy's Hospital Reports," we are promised further evidence on this vital question of treatment; and are glad to find that Dr. Owen Rees has also resolved to join more fully in the inquiry, and to give the results of a certain number of cases treated with mint-water, and an equal number with alkalis, lemon-juice, &c.

It is thought the Venereal Diseases Committee will confine themselves to the practical recommendation of some plan for examining prostitutes in garrison towns.

At the meeting of the Royal Medical and Chirurgical Society, Mr. Moore brought forward an interesting case of an arterio venous cyst developed in the popliteal nerve. It was caused by a blow in the ha; the case ultimately required amputation. There is some doubt as to whether the tumour was innocent or not. Mr. Sibley brought forward a remarkable and rare instance of numerous neuro-matous tumours of a cystic character, both within and without the spinal canal.

At the post-mortem examination there was no disease of the viscera of the chest or abdomen. The brain and the cranial nerves were healthy. On opening the spinal canal a number of tumours were observed connected with the nerves within the membranes of the cord. In the cervical region there were several tumours, and the largest of these (about the size of a large nut) had pressed upon the spinal cord, which at this point was extremely constricted and softened. There were also many neuromata in connexion with the nerves in the lower part of the cord. In some places these were so numerous as to prevent the appearance of beads strung on a thread. The large tumour which was observed during life below Poupard's ligament was found to be connected with the anterior crural nerve. It was enclosed in a fibrous capsule, and on section presented the appearance of a fibro-cellular tumour interspersed with cysts. These cysts were of various sizes, the largest being about the size of an egg, and partly filled with imperfectly organized blood-clots. A second smaller cyst was filled with gelatinous material. The remaining small cysts were filled with clear serous fluid."

Dr. Johnston's work on cholera, which was so lauded in a late number of the journal, has given rise to considerable correspondence.

A "Resident Practitioner" of Brighton draws attention to the manner in which hospital and dispensary charity is administered. The recipients often are not confined to the lower orders; persons in a fair position do not think it beneath them to accept of gratuitous medical advice, and even sometimes to pay another medical man when

they have got tired of the physician who has been attending them for nothing. We fully agree with "A Resident Practitioner" that hospitals and dispensaries are often the means of robbing the neighbouring practitioners.

Dr. Dobell's paper on tuberculosis is completed. He advocates the use of a pancreatic emulsion, which is now manufactured by Messrs. Savory and Moore; his theory is based on the hypothesis that the disease is caused by an abnormal condition of the above secretion. This he endeavours to rectify by the substitution of the pancreatic juice of another animal.

An interesting example of hermaphroditism is related by Dr. Webster. Although the person assumed the dress, &c., of a female, yet the animal instincts and organisation of the male preponderated.

The *Lancet* devotes a leader to the condition of the Fenian prisoners at Pentonville and the hardships which they, as state prisoners, have to undergo in common with the vilest criminals. Whether or not it be due to the severity of the discipline, 10 per cent. of the convicts become insane. Our Government was ever ready to interpose with Russia, Naples, and Austria on the subject of the treatment of their political prisoners, who, in this kingdom have been always looked on with sympathy, but we should take the initiative ourselves, and make, as formerly, some difference between the political and criminal prisoner.

Mr. Hume, who was censured by a coroner's jury for the alleged neglect of a patient, has been called on to resign his appointment:—

"At any rate, up to this time he had always done his duty. Let us suppose that he slightly, or even seriously, failed. A coroner's inquest was held, presided over by Dr. Lankester, and censure of Mr. Hume was expressed by the jury without acquainting him with their deliberations, or giving him any chance of an explanation. We should be extremely happy to hear that Dr. Lankester entered his protest against this monstrous unfairness of condemning a man in his absence, without giving him the opportunity of defence or explanation."

Professor Huxley has recommenced his Lectures on Zoology at the College of Surgeons on Mammalia.

The discussion on pneumonia is continued. Dr. Clark answers the letter of "Vigo" in reference to existence of intervesicular lung tissue.

The Secretary of the New Sydenham Society replies to the correspondent who lately found fault with the working of the Society: his explanation is satisfactory, but discloses the curious fact that, instead of a "liberal salary," the Secretary enjoys the miserable pay of fifty guineas a year, which is less than one would offer to a second-rate carpenter.

Mr. R. Ellis draws attention to a new method of administering chloroform; he uses alcohol first, then ether, and then chloroform, by means of an ingeniously contrived instrument, he is enabled to present either of the anæsthetics separately or united without changing the apparatus.

At Guy's, a patient who had elephantiasis of the leg was subjected to ligature of the external iliac artery by Mr. Bryant; the operation was followed by considerable amendment, but there was a tendency to recurrence of the disease when she assumed the perpendicular position.

Mr. Kempton gives a description of the use of Dr. Richardson's new instrument for producing local anæsthesia; it was used in the extraction of teeth most effectually.

There is no doubt but that Dr. Richardson has put us on the right road in producing a very important result.

The *Medical Times and Gazette* devotes a leader to Dr. Marion Sims' book lately published; it reviews the kind of practice therein detailed in no complimentary manner.

Dr. Tilbury Fox draws attention to Zittman's treatment of constitutional syphilis by means of peculiar decoctions of sarsaparilla.

Two cases of removal of the entire tongue are recorded from Mr. Paget's wards in Bartholomew's: previous to the application of the écarteur the organ was freed from its attachments to the jaw, the mucous membrane and origins of the four genio-hyoid muscles being divided.

HOUSE OF COMMONS.—FEBRUARY 6TH.

SIR G. GREY brought up, by command of Her Majesty, the first report of the Commission appointed to inquire into the origin and nature of the cattle plague, and also the report of the Capital Punishment Commission.

SIR G. GREY gave notice that on Monday next he should move for leave to bring in a Bill relating to the contagious and infectious diseases existing among cattle.

MR. CHILDERS gave notice that on Monday next he should move for leave to bring in a Bill relating to the improvement of the dwellings of the labouring classes.

MR. TORRENS gave notice that on Tuesday, the 20th inst., he should move for leave to bring in a Bill to make better provisions in the laws relating to artisans and labourers.

MR. DOULTON gave notice that on the 13th inst., he should ask the Home Secretary if it were the intention of Her Majesty's Government to introduce early in the present Session a Bill having for its object the preservation of the commons and open spaces round London.

THE CATTLE PLAGUE.

THE official returns for the week ending February 3rd are nearly worthless, as 209 inspectors have not reported in time for the weekly account. These inspectors returned 2304 cases last week. The imperfect totals are 153 fresh cases, against 11,745 in the previous week.

A meeting of the members of the Agricultural Society was held last week at St. James's Hall. Resolutions were passed, the purport of which was to prohibit all movements of live stock, to order that all infected and those in contact with them should be killed, to provide remuneration for owners of animals affected by these measures, and to do all these things by Act of Parliament.

From the last week's Cattle Plague Returns, by comparison with those of the previous week, it will be seen that there have been 23,642 attacked, 9845 deaths, 607 slaughtered, and 2331 recoveries, since January 20:—

ASYLUM FOR IDIOTIC AND IMBECILE CHILDREN.

On the 1st inst. a meeting was held at Charlmont House, Rutland-square, Dublin, to consider the propriety of establishing an institution for the training and educating of idiotic and imbecile children. The meeting was numerous and influentially attended.

The Earl of CHARLEMONT in the Chair.

Mr. Jonathan Pim, M.P., said that it was unnecessary for him to say anything with regard to the melancholy condition of the class on whose behalf the meeting had been called. They were not only a source of expense to their families—not only were they generally unable to do anything towards maintaining themselves, but they generally required such care and attendance as prevented other members of the family with which they were connected from earning their bread. Their habits were often very repulsive, their moral faculties very often depraved, while their education not unfrequently was entirely neglected. The questions for them to discuss were—first, whether anything could be done for the improvement of the condition of these classes; second, whether anything ought to be done; and third, the proper way to attempt to do it. He thought it was evident, from the results of experience, that something could be done—in some cases probably a great deal, in others, perhaps, not very much. Lunacy and idiocy had sometimes been confounded, and the true distinction between them overlooked. Lunacy was the misdirection of an intelligence which already exists, and has already been developed. Idiocy is the non-development or the imperfect development of that intelligence. As sane people were capable of various degrees of instruction, so those who were classed as idiotic were like wise capable of instruction in different degrees. It was only during the last twenty years that this subject had obtained much attention—first in France, then in England, but most of all in America, where it had received greater attention than anywhere else. In England there was a magnificent institution at Earlswood, about thirty or forty miles from London, between that city and Brighton. This was the asylum for the eastern counties of England, and there had also been established one for the north-eastern counties, and another for the northern counties. There had also been one established in Scotland. The Earlswood Asylum was the earliest established, and consequently they had had most experience there. From a paper issued by the Northern Counties' Asylum they could gather some information with regard to the proportion of those in whom improvement was effected, and the character of that improvement. It appeared that of the cases admitted ten per cent. became self-supporting, forty per cent. so far improved that they ceased to use up the time of another person in attending to them; the remainder, with the exception of six per cent., on whom no improvement was effected, all became greatly improved. It was the experience of the conductors of those institutions that they could not, till they had tried, say whether any case would be successful or not. Of all the results of this training, the most interesting was the effect produced by it on the moral and religious feelings. Similar results had flowed from the institution established in Scotland. As to whether anything ought to be done, he thought there could be no question. From statistics, for which he was indebted to Sir William Wilde, it appeared that there were in Ireland 7033 imbeciles or idiots. Of these 403 were in lunatic asylums—places not very well adapted for improving their condition; 21 were in prisons, places much worse for that purpose; 934 were in workhouses. The remaining 5675 were at large, living amongst their own families, and many of them in a wretched condition. In America, where great attention was paid to this class, provision was made by the State for them. He did not believe they could properly effect what they wished to do without the assistance of the State. He thought that assistance should be given in the form of a Parliamentary grant, leaving the institutions at the same time under private care, on the model of the principle applied to reformatories. As to the cost, they should have a large house—one especially adapted to the purpose, and having the workshops and other things which would be necessary to its proper working. Again, these poor people required a very liberal diet (hear). A great portion of the success in their mental training depended upon the improvement of their physical condition. A very large number of caretakers would also be necessary. At first he believed it would be necessary to have one for each inmate. All these things

would entail very great expenditure, and he mentioned them because it would be well that they should know of them beforehand, so as not to cause disappointment afterwards. The building would probably cost £4000, the fittings and furniture about £18,000, and the maintenance of each inmate about £21 or £30 per annum. He had said there were in Ireland 7033 persons of this class. He might add that of these 1642 were Protestants, and 5391 were Roman Catholics. Of course the larger proportion of the Protestants were in the province of Ulster, about 1200 out of the entire 1642 being resident there. Mr. Pim resumed his seat amid the applause of the audience.

The Chairman then called on the Archbishop of Dublin to move the first resolution.

His Grace the Archbishop of Dublin, in moving the first resolution, said—I am sure, my lord, all here present are obliged to your lordship for the permission and opportunity you have given us for the consideration of so interesting and important a subject under this roof, where many things which deeply interest Ireland, and deeply concern her welfare, have been discussed in times past (hear). I do think there is probably nothing which has more right to touch our sympathies than that before us. I think all here present will recognize the zeal and energy that have been shown in this work for the alleviation of human suffering, and which we always find exhibited on the part of the medical profession. We recognize in this matter their leadership, and it is they who have provoked us to an interest in a work so good as this is. I am sure we might have gone on looking at this evil, and giving it but helpless thought, but that they have stirred themselves so energetically as they have done. At the same time, it is one of the saddest and most encouraging facts that, as we look abroad upon the world, and see how much sorrow, trouble, poverty, and distress there are there,—it is one of the saddest facts that there should be so much remediable that has not been remedied, and one of the most encouraging facts that, although it has not been remedied, it is still remediable, because it tells us that it only wants a little more earnest and Christian feeling and sympathy, only a little more earnest toil and labour to assist in removing part of that great mountain of woe which seems to oppress the human race. It is an encouraging fact that the late Prince Consort—so eminent, not for vague and thoughtless benevolence, but for a benevolence actuated by thoughtfulness and discrimination—should have taken so great an interest in a similar institution at Earlswood. Not merely did he lay the first stone—for that he could not avoid as a piece of official work—but he took the deepest interest in its success: an interest which has been inherited by the Prince of Wales, who is about to lay the first stone of a large wing to that magnificent institution. I do earnestly trust that, while England is performing her part in this work, while Scotland is doing her part, Ireland will not be altogether behindhand; that, seeing what may be done, we will address ourselves to the doing of it, and that we will not part to-day without having taken some steps towards the establishing of an institution for the protection, training, and education of the idiotic and imbecile, who, not being able to plead for themselves, as the motto of Earlswood runs, have the greater claim that others should plead for them. His Grace concluded by moving the following resolution:—

“That the condition of the idiotic and imbecile being such as to demand our cordial sympathy, this meeting learns with pleasure that much can be done for their education and improvement, and resolves that immediate steps shall be taken to establish an institution for their protection, training and education.”

The Bishop of Down and Connor seconded the resolution. Mr. Pim had stated that the institutions which already existed in Ireland for the treatment of the insane were supported by the State. They were not exactly what was commonly called supported by the State, but rather out of the county rates. He thought, considering the machinery already existing, that it might be well to inquire whether arrangements could not be made by which each county should send its own idiots and imbeciles to such an institution as it was now proposed to establish, and, through means of a rate levied for the purpose, supply the means of support, and thus secure the permanence of the institution. It would also extend the interest in the institution itself. That the ordinary asylums were not fitted for the reception of idiots and imbeciles had been clearly shown by the hon. member, Mr. Pim, who showed that they required peculiar

care and instruction, and a different description of diet from that usually given to the inmates of lunatic asylums. It was for that reason that he agreed with the proposal to transfer these classes to an asylum provided by Christian benevolence.

The resolution was then put, and carried unanimously.

The Rev Dr. Urwick moved the second resolution:—

“That the following noblemen and gentlemen be requested to act as a committee (with power to add to their number), and are hereby empowered to take such steps as they may deem advisable for the carrying out of the foregoing resolution.—[Here follow list.]

Mr. Alexander Parker, in rising to second the resolution, said that he did so with great pleasure. It was astonishing how the existence of a little enthusiasm in one person kindled a like enthusiasm in others. Dr. Kidd had been enthusiastic in this work, and had succeeded in imparting some of his enthusiasm to others, refusing to take any excuse as to their being already overloaded with work. If, however, some of them should fall off a little in the real working of the institution, he hoped that others would be found to take their place (hear).

The resolution was passed unanimously.

Mr. J. C. Colville moved the third resolution, to the effect that a subscription list be opened for the purpose of carrying out the foregoing resolutions.

Dr. Stewart said he would be glad to put down his name as a subscriber of £50, and if necessary he would give £50 more.

Mr. McMaster moved—

“That this meeting think it desirable that local committees should be formed in the principal towns throughout Ireland to enlist support for the institution, and make its object generally known.

The Rev. Mr. Stevenson seconded the resolution, which was agreed to.

Professor Ingram moved—

“That the committee be empowered to elect presidents and vice presidents of the institution, who shall be *ex-officio* members of the general committee.”

Mr. Swithorpe seconded the resolution, which was carried unanimously.

Nearly £1000 was subscribed in the room for the objects of the charity.

Correspondence.

POOR-LAW MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall feel obliged by your giving insertion to the annexed letter, that the Poor-law Medical Officers may be made acquainted with the steps taken towards an improvement in the Medical relief of the poor.—Yours, &c.

RICHARD GRIFFIN.

12, Royal-terrace, Weymouth, 3rd February, 1866.

SIR,—Since the commencement of this year a large number of Poor-law Medical Officers have sent their subscriptions to enable me to defray the necessary expenses consequent upon an application to be made to Parliament, and the printing of a pamphlet to be sent to each Member of the House of Commons, demonstrating the necessity of a thorough revision of the present wretched system of Medical relief to the poor; but prior to this procedure I feel I should best consult the interests of all parties concerned by laying before you, as the head of this great department, which has annually under its management over a million and a quarter of sick poor, the draft of a bill which appears to me would, if passed, be of national advantage, and if you would take charge of it, or of one of similar import, and introduce it into the House of Commons, or make it a part of your new Poor-law Continuance Bill, I feel sure you will immensely benefit the public. That you may have knowledge of the sentiments of the Poor-law Medical Officers on this subject, I request you will permit such of them as can spare the time to wait upon you as a deputation, and if you will fix a

time, giving me a clear fourteen days notice, I will call them together for the purpose, and should you in the interval desire a private interview with me, relative to any arrangements, I will gladly wait upon you any day you may fix.—I have the honour to be Sir, your obedient servant,

RICHARD GRIFFIN.

The Right Hon. C. P. Villiers, M.P.,
President of the Poor-law Board.

THE CATTLE PLAGUE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Can you or any of your readers inform me if the tincture of the sesquichloride of iron, either with or without quina, has been tried in the treatment of the cattle plague? and if so, what has been the result? These two drugs, with many others, are very useful in fevers in the human subject, why may they not be so in the case of the rinderpest (apparently at least a kind of cow fever) in the early stages of the disease? It is the practice in this neighbourhood of parties having cattle to pay into Cattle Associations certain calls or subscriptions in case of pleuro-pneumonia appearing among their stock, when they receive out of the Society a sum of money, and make up the full value of the animals by selling them for what they get as human food.

It is also the practice here, in cases of nervous or other excitement, as in parturition of cows, sheep, pigs, &c., resulting in the death of the animals, for the butcher to stick and dress the carcasses, and then sell them for human food. This is also done in all accidents, dropsy, diseases of the heart, lungs, liver, &c., thereby engendering fevers and many other diseases in the human being, whereas if these associations would agree to make sufficient calls upon their members, they would be able to pay the full value of the cattle, which should be buried, and thereby prevent much sickness and misery. Apologising for troubling you with this, I remain, Sir, your obedient servant, THOS. G. E. BROWN.

Waddesdon, Aylesbury, February 8th, 1866.

BILL FOR PREVENTING THE FURTHER SPREAD OF THE CATTLE PLAGUE.

THE Home Secretary moved, on Thursday night last, for leave to bring in a Bill for the prevention of the further extension of the cattle plague. The principal clauses in the measure were those ordering the immediate destruction of all infected animals, and empowering Magistrates to order the killing of healthy beasts if they see shall necessity. Owners to be compensated from a special tax to be levied in each county to the amount of two-thirds of the value of the animal, being not more than £12 in the case of an infected beast, and £25 of a healthy one. We hope to give the measure as fully as possible in our next.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following Members of the Colleg., having been elected Fellows at previous meetings of the Council, were admitted as such on the 8th inst.:—

Guy, Thomas, Doncaster; diploma of Membership dated July 2, 1841
Harris, Clement Mears, Wootton-under-Edge; Dec. 21, 1838.
Rowe, Charles Reynolds, Wimborne Minister; June 1, 1835.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise on the 1st inst.:—

Adams, Josiah Oake, Plymouth.
Bury, Henry Charles, Whetstone, N.
Grace, Edward Mills, Downend, Bristol.
Rundle, Henry, Plymouth.

ROYAL COLLEGE OF PHYSICIANS AND SURGEONS, EDINBURGH: DOUBLE QUALIFICATION.—The following gentlemen passed their final examinations during the recent

sittings of the examiners, and were admitted L.R.C.P. Edin. and L.R.C.S. Edin. :—

Anderson, Colles Litchford, Madras.
Grier, William John, Co. Longford.
Hackett, Arthur Luke, Cork.
Holmes, William Hugh, Cork.
Johnstone, Howison Jas., Co. Longford.
Jones, David Joshua, Carmarthenshire.
Loos, James, Ceylon.
McKenna, Cornelius John, Tipperary.
Miller, Lewis, Dublin.
Parke, Samuel, Gilford.
Pattie, Robert, Dumfriesshire.
Ritchie, Alex. Ramsay, Edinburgh.
Thompson, Thos. Alex., Carrickfergus.
Wylie, William, Poyntzpass.

And the following gentlemen passed their first professional examinations :—

John Kerr Davidson, Wick; Edward E. Purcell, Limerick; Henry Bath, Glastonbury; Richard Young, New Lanark; John Riddle, Ballybay.

SCHOOL OF PHYSIC, TRINITY COLLEGE, DUBLIN.—The following Gentlemen passed the Examinations for the Degrees in Medicine and Surgery last week :—

Medical Degree Examination.

Thomas E. Little.	Christopher Armstrong.
William Morton Harman.	Michael Shanley.
William Robert McDermot.	William J. S. Boake.
James Thompson.	William H. N. Stanford.
William Henry Steele.	Richard S. Smallman.

Surgical Degree Examination.

James McCutchan.	Edward Kough.
Richard Vesey.	Samuel B. Gamble.

SAMUEL HAUGHTON, Medical Registrar.

ROYAL COLLEGE OF SURGEONS OF IRELAND.—The following Gentlemen passed on February 10th :—

Letters Testimonial.

Robert Alexander Caldwell, Coleraine.
William Ireland Wheeler, Dublin.
Navy Assistant-Surgeons.
William John Rankin, L.R.C.S.I.
Edward Wilberforce Leet, L.R.C.S.I.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—The following gentlemen passed the final examinations during the recent sittings of the examiners, and were admitted Licentiates of the College :—

Douglas, John Charles, Wigtownshire.
Greene, William Thomas, Dublin.
Turnbull, G. Wardlaw, Linlithgowshire.
Walsh, John Aloysius, Carrick-on-Suir.
Wright, John, Derbyshire.

And the following gentleman passed his first professional examination :—

Rollt Ayre Smith, Monkwearmouth.

UNIVERSITY OF CAMBRIDGE ---The Board of Medical Studies has issued a report recommending alterations in the regulations for degrees in medicine and surgery, of which the most important is a rearrangement of the examination so that the subjects of the first examination shall be—Chemistry, with Heat and Electricity, Botany, the Element of Comparative Anatomy, Human Anatomy and Physiology and those of the second examination shall be—Pharmacology, Pathology, and the Practice of Physic, Clinical Medicine, and Medical Jurisprudence.

DEATHS IN THE AMERICAN ARMIES.---The War Department computes the number of deaths in the Union armies since the commencement of the war at 250,000, and that of the Southern soldiers at least to 225,000, making at least 475,000 lives that have been lost. At Gettysburg, 23,000 Union soldiers were killed, wounded, or taken prisoner. General Grant's losses, from the time he crossed the Rapidan until Lee's surrender, were about 90,000.

MR. FAULL, the medical officer who was drowned in the *London*, had been once assistant medical officer at Colney Hatch Asylum. His age was only 37. He has several times been to Australia in Messrs. Wigram's ships.

CONVICTION FOR SELLING ADULTERATED WINE.—A wine merchant in France was lately fined £20 and imprisoned for a year, for selling wine into which a quantity of litharge had been put. Three persons, it is said, had been killed, and several paralysed, who had drunk it.

PHARMACEUTICAL ETHICS.—Mr. Ince is about to write a treatise on Pharmaceutical Ethics, at the instance of the Pharmaceutical Conference.

DR. OPFOLZER of Vienna has inflammation of the lungs; but Dr. Skoda does not consider him to be in any imminent danger.

DR. WILLIAM A. HAMMOND, late Surgeon-General, United States Army, has come to Europe in charge of a grandson of the late John Jacob Aston of New York.

THE PROFESSION IN PERU.—The *Medical Times and Gazette* says that there are but two hundred legally qualified medical men in Peru; and that charlatans there reap a splendid harvest.

VOMIT OF YELLOW FEVER.---In specimens of the vomit (says Mr. J. Hogg) from the yellow fever, sent to me from Bermuda, I found a large admixture of spores and torulae, with altered blood-corpuscles and disintegrated epithelial scales.

EYE DISPENSARY OF EDINBURGH.—Last week the annual meeting of this Institution was held in the Dispensary, Cockburn-street—Dr. Dunsinure, President of the Royal College of Surgeons, in the chair. The annual report, which was read and adopted, stated that since the commencement of the Institution in 1822, nearly 42,000 cases had been treated in it, all gratuitously; and that the number of new cases treated annually was about 1400. A vote of thanks was given to the officers of the Institution, which terminated the proceedings.

GLASGOW—POLICE BOARD.—The ordinary meeting of the Glasgow Police Board was held yesterday—the Lord Provost presiding. From a medical report by Dr. Gairdner, it appeared that during last fortnight the occurrence of 218 cases of fever had been reported, against 193 during the preceding fortnight, and four cases of small-pox, against one and 149 cases fewer than those of which returns were given during the previous two weeks. Mr. Ure, in moving the adoption of the minutes, referred to the increase of fever cases shown by the above figures, and remarked that the number was ten fewer than the cases reported a month ago, in a year ago. The minutes were confirmed.

OZONE AND HEALTH.—Lastly, we gather from what has gone before, a few facts bearing on hygienic measures, general and special. We may learn that Ozone is used up in crowded localities, and its presence is essential for the removal of the products arising from decomposing organic remains, no mere attention to ventilation, however important that may be, can suffice to make the air efficient for supporting healthy life unless the air be rendered active by the presence of Ozone. Hence it is an absurdity of the worst description to build hospitals for the sick in the midst of the crowded localities of the poor, and to ventilate them with air that has swept its way over a sea of ammoniacal compounds derived from the living and the dead. Hence, human dwellings built on the borders of lakes or pools charged with organic debris, or built near manure heaps, or over sewers, or on ground saturated with putrefying substances, become necessarily the centres of the fever type of disease; not by necessity, as is vulgarly supposed, because the inhabitants are conscious of "smell," but because the air they breathe is reduced in active power, and poisons are being generated around them to which they are constantly exposed, and before which they fall a ready prey.—*Dr. Richardson in "Popular Science Review."*

THE ROYAL SOCIETY.—A ordinary meeting of the Royal Society was held on the 5th inst., in the Royal Institution—Sir David Brewster in the chair. Dr J. Matthews Duncan read a paper illustrated by twenty-five tables of statistics on "The Laws of Human Fertility." Dr. A. Crum Brown delivered a brief address on "The Classification of Chemical Substances by means of Generic and Specific Radicals." The lecture was illustrated by several diagrams. Professor Tait read two short papers on "The Condensation of Air in an Air Bubble under Water," and on "Some Geometrical Constructions connected with the Elliptic Motion of Unresisted Projectiles." Sir David Brewster presented the Society with several beautiful specimens of the "fairy stones" found in Elwand Water, near Melrose. The stones were accompanied by a short paper, read by Professor Tait, giving an account of their discovery, and describing their probable formation. After disposing of some private business, the meeting separated.

BIRTHS and DEATHS Registered and METEOROLOGY during the Week ending Saturday, February 3, 1886, in the following large Towns:—

Boroughs, &c.	Estimated Population in middle of the Year 1886.	Persons to an Acre. (1886.)	Births registered during the week ending Feb. 3.	Deaths.*	Temperature of Air (Fahr)			Rain Fall.	
					Corrected Average Weekly Number.	Highest during the Week.	Lowest during the Week.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29.553 in. The atmospheric pressure was 30.05 in. on the morning of Sunday; it fell to 29.13 in. on Friday, and rose to 29.82 in. on Saturday.

The general directions of the wind was S.W. and W. The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the 10 years 1851-60 to the present time.

Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in other towns.

The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in workhouses situated outside the municipal boundaries.

The mean temperature at Greenwich during the same week was 46.9 deg.

The usual return from Liverpool not having been received, averages of the births and deaths in the previous six weeks have been substituted for the correct numbers.

MEDICAL DIARY OF THE WEEK.

WEDNESDAY, FEB. 14.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—1 p.m. Prof. Huxley, "On the Classification and Structure of the Mammalia."
MICROSCOPICAL SOCIETY.—8 p.m. Anniversary Meeting.

THURSDAY, FEB. 15.

ROYAL INSTITUTION.—p.m. Professor Tyndall, "On Heat."
HARVEIAN SOCIETY OF LONDON.—8 1/2 p.m. Dr. Camps, "On Railway other Accidents attended with Violence: their Effects on the Nervous System."

FRIDAY, FEB. 16.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Prof Huxley, "On the Classification and Structure of the Mammalia."
ROYAL INSTITUTION.—8 p.m. Col. Sir H. James, "On the Ordnance Survey of Jerusalem."

SATURDAY, FEB. 17.

ROYAL INSTITUTION.—3 p.m. Prof. Westmacott, "On Art Education, and how Works of Art should be viewed."
METROPOLITAN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—7 1/2 p.m.

NOTICES TO CORRESPONDENTS.

Mr. Griffin's letter is inserted.

Mr. T. J. E. Brown.—The letter is inserted.

Mr. J. T.—The letter has been received.

A House-Surgeon.—The plan is recommended only, or chiefly, in cases of fractures received in the field of battle.

Dr. H.—The reports will be acceptable.

Lector.—Formic acid is so called, because it was originally obtained from ants (formica), and it is a curious circumstance that a liquid distilled from ants is used in some Northern counties as an intoxicating drink.

The Army Medical Department, Netley.—The copy of the Examination Papers has been received.

A Poor-law Medical Officer.—We believe that the Poor-law Board does not allow fees for cases of revaccination, but a letter directed to the Board will procure an official reply upon the point.

X.—At Cambridge it is necessary to pass the Previous Examination, which is analogous to the Matriculation Examination of the University of London.

Mr. R.—The suggestions shall be attended to.

THE GRIFFIN TESTIMONIAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—The following subscriptions have been further received on behalf of the above fund:—

Dr. J. Birkbeck Nevins, Liverpool, £0 10 6
Amount previously announced 133 9 9
Received at "Lancet" office 9 9 0

Yours obediently,

ROBERT FOWLER, M.D., Treasurer and Hon. Sec.

145, Bishopsgate-street, Jan. 24, 1885.

BIRTHS.

MOFFAT.—At Thornhall, Polmont, on the 3rd inst., the wife of Robert Moffat, M.D., of a daughter.

EVISON.—At M.Inthorpe, Westmoreland, the wife of Hanson Evison, M.R.C.S. Eng., of a son.

GROSVENOR.—The wife of G. Fox, Grosvenor, M.D., prematurely of a son.

HARMER.—At Pix-hill, Haukhurst, the wife of Dr. W. M. Harmer, of a daughter.

HASTINGS.—At 56, Curzon-street, the wife of Dr. Cecil Hastings, of a daughter.

HOVELL.—At Clapton, the wife of Dr. de Berdt Hovell, M.R.C.S. Eng., of a son.

JONES.—At Wrexham, the wife of T. Eytton Johns, M.R.C.S. Eng., of a daughter.

LANGSTON.—At Broadway, Westminster, the wife of Thomas Langston, M.R.C.S. Eng., of a daughter.

MAY.—At Reading, the wife of George May, jun., F.R.C.S. Eng., of a son.

MURCHISON.—At 79, Wimpole-street, W., the wife of Charles Murchison, M.D., of a daughter.

PICARD.—At 34, Abbey-road, St. John's-wood, the wife of P. Kirkpatrick Picard, M.D., of a son.

SAVAGE.—At Bordesley, Birmingham, the wife of Thomas Savage, M.D., of a daughter.

STUART.—At Chainbridge, Berwickshire, the wife of Charles Stuart, M.D., of a son.

TAYLOR.—At Woodstock, Oxon, the wife of Frederic Taylor, M.D., of a son.

TRAQUAIR.—At Pau, France, the wife of T. G. Traquair, M.D., of 1, Eccleston-square, of a son, stillborn.

Feb. 2, at Molesworth-street, the wife of Thomas W. Grimshaw, Esq., M.B., of a son.

Jan. 30, at Clanvill Lodge, the wife of Captain Tyssen, R.N., of a daughter.

MARRIED.

PEET—GIRAUD.—On February 6, at St. Mary's Church, Dover, John Peet, M.D., Surgeon-Major Bombay Army, to Nind Laura, daughter of Herbert Giraud, M.D.

WATSON—WATSON.—On February 3, at St. Bartholomew's Sydenham, George H. Watson, M.R.C.S. Eng., Caroline Amelia, eldest daughter of the late Robert Watson, Esq.

WALLACE—ROCHE.—Feb. 1, at St. Kevin's Church, by the Rev. Mr. Patten, and afterwards by special license, at the Augustinian Church, John-street, by the Rev. T. Brown, P.P., Limerick, assisted by the Rev. W. Sullivan, O.S.A., London, Richard Wallace, Esq., M.D., to Margaret Teresa, second daughter of the late Maurice Roche, Esq., and niece of Alderman Tinsley, J.P., Limerick.

BRIGSTOCKE—TOMPKINS.—On February 1, at St. Luke's, Cork, Richard W. J. Brigstocke, Surgeon, R.N., to Lizzie, youngest daughter of W. J. Tompkins, Esq.

CHIZABLE—MURCROFT.—On January 31, Walter B. Chizable, M.D., to Anne, youngest daughter of the late William Murcroft, Esq.

ELLIOT—BRADLEY.—On January 20, George S. Elliot, M.D., to Elizabeth, widow of the late William O. Bradley, Esq.

GALE—DRIVER.—On February 1, at Heaton Norris, A. Stanley Gale, M.B., to Miriam Driver, the adopted daughter of the late Samuel Benison, Esq.

GILBERT—TACON.—On February 1, at Brodborough, Stroud, Edward G. Gilbert, M.R.C.S. Eng., to Selina Anne, eldest daughter of Robert Tacon, Esq.

HENRY—DELANEY.—On February 1, at St. John's Church, Islington, James Henry, M.D., Surgeon R.N., to Nannie, eldest daughter of John Delaney, Esq.

HILLS—PARKER.—On January 25, at Edlington, Rolland Hills, M.R.C.S. Eng., to Harriet daughter of Edward Parker, Esq.

MAURICE—KINDERSLEY.—On February 1, at St. Paul's, Knightsbridge, James B. Maurice, M.D., to Mary Agnes, only daughter of the late N. W. Kindersley, Esq.

WHITE—COMBE.—At St. Paul's Church, York-place, on the 2nd inst., by the Rev. James E. Montgomery, M.A., Francis Buchanan White, M.D., elder son of F. J. White, M.D., 1, Perth, and of Pelsham, Dorset, to Margaret Juliet, youngest daughter of the late Thomas Corrie, Esq. of Stirlston.

DEATHS.

HENRY G. M. ALLANSON, M.D. St. And., at St. George's-terrace, Sheffield, on January 28, aged 37.

Dr. J. J. BARTON, at Brighton, on January 29, aged 62, formerly of Buxley.

GEORGE BIRKETT, M.D. Lond., at Northumberland House, Stoke Newington, N., on February 1, aged 47.

THOMAS E. T. COLMAN, M.R.C.S. Eng., at Wymondham, Norfolk, on January 24, aged 58.

GEORGE FOTHERGILL, L.S.A., at Moreland, Westmoreland, on January 16, aged 60.

JAMES LEITCH, L.R.C.S. Edin., Surgeon, R.N., at Crieff, Perthshire, on January 16, aged 84.

CORRIGENDA.—In Dr. Glogolegan's letter on "Operations on the Windpipe," p. 135, line 26, for "insufficient air," read "insufficiently warmed air;" p. 136, for "gum elastic," read "gum-elastic tubes;" for "collar," read "collar;" for "edge," read "the edge."—In Dr. McKinlay's paper "On Amputation by Flaps in the Leg," in last week's issue, in the second line from the bottom, for "Mr. Synes" of Dublin, read "Professor Syme" of Edinburgh.

A REMARKABLE CASE OF LITHOTOMY.

By CHRISTOPHER FLEMING, M.D., F.R.C.S.I.,
SURGEON TO THE RICHMOND HOSPITAL.

SUDDEN RETENTION OF URINE FROM ENLARGEMENT OF THE PROSTATE GLAND; EXTERNAL CHARACTERS OF THE URINE; DECEPTIVE RATIONAL SIGNS OF STONE IN THE BLADDER; PHYSICAL SIGNS, CONCLUSIVE; MEASUREMENT OF THE STONE; OPERATION OF LITHOTOMY; REMOVAL, AT THE OPERATION, OF SIX LARGE CALCULI FROM THE BLADDER; VIOLENT SECONDARY HÆMORRHAGE; NATURE OF CALCULI; RECOVERY COMPLETE.

A MAN, in his 63rd year, was brought to the Richmond Hospital, during my morning visit, with retention of urine, which, for the first time, attacked him the evening before, after exposure to cold. He was a tall able man, in good bodily health. For the last four years he had been employed as a drayman in an extensive brewery in this city, and for many years previous he had been in one of the engine-rooms attached to the establishment. On repeated occasions, for the last ten or twelve years, he had uneasiness in the loins, extending along the course of the ureters, towards the region of the bladder; had, at irregular intervals, frequent and urgent micturition; the urine was often suddenly interrupted in its stream; but yet, with all those symptoms, he continued to discharge his duties, the attacks passing off after some severe paroxysms, and returning after very irregular and lengthened intervals. He never had hæmaturia, and did not suffer more acutely while engaged in his daily occupations. On no occasion had he retention of urine, nor had he ever applied for medical advice until on the present, when he was forced to the hospital by a fellow-workman. The man was now suffering much, and his bladder was so largely distended as to be distinctly felt in the hypogastrium. I passed, in the erect posture, a gum-elastic catheter, and drew off a large collection of urine. At the end of its removal I thought I felt a calculus strike against the instrument, but at the moment attributed the sensation to one of those fluttering movements so commonly communicated in such cases. I induced the man to enter the hospital, and admitted him in September, 1859. On the following day I examined a specimen of the urine drawn off; its odour was natural; it was of a deep straw colour, acid in its reaction, and had a density of 10.20. Its deposit of rest was copious, opaque, and fawn coloured, and studded throughout with minute red particles resembling Cayenne pepper. Under the microscope numberless crystals of lithic acid, of all shapes and forms, were clearly discernible; the glass vessel was clouded with a deposit of lithate of ammonia, which gave it a muffled appearance, and caused the fluid to present a deceptive muddiness. The following morning I drew off the urine with a silver catheter, as the man lay in bed, when the presence of a stone in the bladder was unequivocally ascertained. A few days subsequently, before drawing off the urine, I introduced a flat-bladed lithotrite in the same position, and at once, without the slightest difficulty, felt and caught a stone, measuring at least an inch, when, finding some delay in disengaging the stone from the grasp of the lithotrite, I got the sensation during its movement that another stone was in the bladder. Although the

instrument passed without much obstruction, it was yet obvious that it required to be pushed to a great length before it fairly reached the cavity of the bladder, and, on examining the prostate gland a considerable enlargement of it was discovered.

The operation of lithotomy was decided upon, as well from the condition of the bladder and that of the prostate gland as from the size of the stone and the suspicion of the existence of a second. The condition of the urine augured a sound state of the kidneys and bladder. After the usual preliminary preparations the lateral operation of lithotomy was performed on the 29th September. Chloroform was used, some brandy and egg having been previously given. Full anaesthesia was produced, and the usual steps of the operation gone through without any annoyance beyond that of having to encounter a very deep perineum. A stone was quickly removed, the size of which being under that indicated by the previous measurement, and its shape being peculiar, caught my attention, when I passed my finger again into the bladder, and on five successive introductions caught the calculi (six in all) shown in Fig. 4 in the Plate. There was some sharp hæmorrhage which was quickly controlled by the "canule à chemise," and all proceeded most satisfactorily until the eighth day after the operation, when an alarming hæmorrhage suddenly supervened. I was urgently sent for to the hospital, and found that all the ordinary efforts had been made by the resident pupils to arrest the bleeding without success. The wound was filled with coagulated blood; blood was also trickling from it and from the urethra, and there was very severe tenesmus. I cleared out the wound and the bladder of a quantity of semi-coagulated blood, and reintroduced the canula, protected with a collar of dry sponge securely tied round its vesical end, taking the ordinary precaution of leaving the openings of the instrument free, and securing all with firm pressure. Wine, opium, and ice were given, and a temporary control of the hæmorrhage effected. Again, however, it recurred with even greater violence, accompanied with forcible tenesmus, and the escape of fluid feculent matter. I now directed, in addition, a piece of ice, shaped as a bougie, to be introduced into the rectum, when, learning from my pupil that it could not be accomplished, I prepared the ice myself, and finding it obstructed about one inch and a half or two inches from the anus, I passed up my finger and felt the whole rectum blocked up with a large accumulation of hardened feces. The course of proceeding was now obvious; the feces were mechanically removed and the rectum well washed out. The hæmorrhage at once ceased and never recurred, and the case progressed steadily, the use of the catheter after the operation of lithotomy not having been required, and the bladder ultimately recovering itself completely.

This man left the hospital free from any urinary suffering in the early part of the November following, and has often presented himself since that period, no symptoms of his former complaint having recurred.

The deceptive character of the rational signs of stone in the bladder in this case marks the necessity for caution on the part of the surgeon in his examination of that organ where prostatic disease is present.

The value of the manœuvre specified with the object of detecting the presence of more than one stone in the bladder will at once be admitted, as well as the selection of the operation of lithotomy under the circumstance of the case, whilst the cause of the occurrence of the secondary hæmorrhage after that operation is specially important to bear in mind.

The weight of the calculi removed, when dried, was more than one ounce and a half: their shape irregularly spherical, but without absolute facets: their surfaces smooth, and their consistence very fragile. The measurement of each by the lithometer varied from one inch and a half to a little more than half an inch in their respective diameters. Their composition, according to the analysis of Dr. Grim-

shaw, was principally lithic acid with lithates. Their outlines, form, natural appearances, and structures, are most truthfully delineated in an illustration accompanying some remarks of mine on lithotripsy and lithotomy, in the last number of the *Dublin Quarterly Journal*.

OBSERVATIONS UPON PAU,

SANITARY, MEDICAL, AND ECONOMIC, AS A WINTER RESIDENCE

FOR ENGLISH CONSUMPTIVE INVALIDS.

By CHARLES R. MAXWELL, L.R.C.P.Lond. and Edin.

PAU, situated in the department of the Lower Pyrenees, France, has for the last forty years been more or less resorted to by English patients, either suffering from, or threatened with, phthisis, under the impression that their lives would be prolonged, or their sufferings mitigated thereby. After crossing the English Channel, the passage of which is generally very rough, and trying to those not possessing "sea legs," a journey by land of 650 miles remains to be accomplished to reach Pau. The times of departure and arrival of trains on French railways are extremely inconvenient to invalids; there are seldom more than two departures *per diem*, one early in the morning, one late in the evening; the consequence is, patients arrive at an hotel about twelve at night or two in the morning, and have to start again at the same uncomfortable hours. Now, I say that damp sheets, and other bedroom inconveniences or necessities, are not well looked after or remedied at such untimely hours; matters regarded as of small moment by those in health, but of vital importance to the sick. Looking after luggage need not detain us long; they manage that matter better in France than we do in England; but a very small weight is allowed to each voyageur to be conveyed free; it is all weighed before starting, and every pound of overplus has to be paid heavily for. I heard of a lady being so fatigued by the journey that she kept her bed for nearly a week, and she was *not* an invalid either. Arrived at Pau, two hotels will be ready to receive you, the Hotel de France, à la Place Royale, and the Hotel de la Poste, Place Grammont, both are well and honourably conducted, and you will find in either of them all the comforts you are likely to meet with out of your own country. The Place Royale is a space somewhat in shape of a parallelogram; extent about four acres; surrounded on three sides by buildings of great elevation, open to the south; it is, in fact, an elevated plateau, being higher by 200 or 300 feet than the country in front, which intervenes between Pau and the base of the lowest Pyrenean range; this country is flat, has a river and streamlets meandering through it; is excessively swampy, abounds with rank vegetation and decaying vegetable matter, which, being acted upon by the intense heat of a southern sun, would, I imagine, be an inexhaustible source of malaria, and form one of the atoms that make up the climate of Pau. At the south end of this Place Royale, close under it and built in the low ground beneath, stands a large hot water bath establishment in full work, the numerous twenty-four chimney pots of which rise just to the level of the Place, vomiting forth columns of smoke, which hang about the spot; this, added to the vapours of fried fat from the culinary operations at the surrounding houses, roasted coffee, tobacco smoke (for a Frenchman is seldom without a cigar in his mouth), all of which hug this confined spot, and the peculiarity of the atmosphere of Pau, being one of stagnation, form items in what the poor consumptive patients fondly imagine is the *fresh air* they are breathing; added to these *desagrémens* are various reminiscences under walls and in corners, bad enough by day and worse by night, when some seek the air after sunset. A feeble attempt is made on Thursdays and Sundays by the military band playing on this Royal place to get up a fashionable promenade. In the summer and early autumn

it plays after sunset (much too late for an invalid to sit out of doors) by lamp light. Leaving the Place Royale, and proceeding through the town, we come to the Chateau, in the garden of which is a terrace, with a southern aspect, a nice gravel walk and a parterre of flower beds, a row of lime trees, and seats, clean and well kept. The view of the mountains hence is very pretty, and the spot would form a nice lounge, were it not for the annoyance of a brewery, the tall chimney of which so often vomits forth clouds of black smoke, which being shut in by the Chateau behind, completely fills this space and renders it impossible to stop there.

Leaving the terrace we come to the park, a continuation of the elevated ridge we have just left. It is a narrow strip of ground, bounded on the south side by the alluvial flat, river, &c., before mentioned; on the north by a narrow parterre and the main road leading to the railway station.

It extends about $1\frac{1}{2}$ miles, is finely timbered, intersected by numerous well-kept walks, with many good seats placed at intervals, and there is a fine view of the Pyrenees therefrom; it is resorted to more or less as a promenade; on the north side, a broad walk extends the whole length of the flat. This is the place where a good private band, which the town of Pau should possess, ought to play daily during the winter season; fashionable promenading, does not, however, seem to suit the tastes of the Pau visitors, who spend their time by day mostly in riding and driving; for a fashionable place of resort you must go to Nice. Pau, however, possesses the finest site for a promenade in Europe; the avenue Port Neuve, a mile long, quite straight, planted with three rows of handsome oak trees; two central walks, thirty feet wide each, abundance of seats, an excellent carriage road all round; it runs east and west; view of Pyrenees on south side; the country immediately round, consisting of nice grass fields and hedge-rows, with elegant villas built here and there; if a cap-full of fresh air is to be had anywhere at Pau, it will be found there; yet this beautiful spot is comparatively deserted. There are a great many large and handsome houses at Pau, some private, but mostly let in flats as "apartments meubles," they average each in price from £50 to £150 English for the season, attendance not included, and you must hire or bring your own linen and plate. There are two clubs here—one French and one English—both in a flourishing condition; three churches, two English, one Scotch; and a pack of fox hounds. I believe there is much evening society amongst the English, who are mostly the same families, having got accustomed to the place come every winter and are known to each other; a stranger coming here without an introduction to at least one family, would, I think, find the *entrée* to these reunions very difficult, perhaps impossible; as foreigners generally remark, the English are very shy of each other, unless acquainted, all over the world, no doubt they possess sterling good qualities, and are composed of good intentions, but can hardly be accused of possessing the talent of readiness in making them apparent.

The fulsome praises bestowed by many French tradesmen upon the articles they have to sell, must be received with a grain of allowance, all is *couleur de rose* with them: proceed with caution, buy but little at a time to try it, it will generally be found *not* to come up to the terms of its advertisement. Some dealers in wines and ales, spirits, &c., charge 2*d.* or 5 sous for each bottle, and will *not* deduct that sum, as is done in England, on receiving the empty bottles, which become a requisite to your French *bonne*, who sells them when you are gone. It is very probable this tax is not levied on French customers, who won't stand any nonsense: "mony a mickle maks a muckle," and a large family consuming perhaps 300 or 400 bottles of wine, beer, in the season, and paying 2*d.* a piece for them, would find it amount to a respectable sum to be added to the general dearness of things: refuse to purchase where you see five sous put on to the price of

each bottle of wine; even the bottle itself is calculated to deceive; hold it up, and look at its under part, you will see that it runs up a fourth of the height of the bottle, and terminates in a thick lump of glass, the weight of which adds to the deception and leads the unwary to suppose they are getting more of its precious liquid contents than they do. What looks like a quart bottle here, holds about an Imperial pint, more or less, English measure. In reviewing trade operations at Pau, I cannot refrain from making honourable mention of the Pharmaceutical Establishment of Monsieur Ménon, Rue Préfecture, 45; himself highly talented, gentlemanly, and obliging, he is assisted by a German gentleman who acquired his professional knowledge in one of the largest and best conducted establishments in London. The best drugs are kept here, many *recherché* requirements of luxury, English patent medicines, and physicians' prescriptions are carefully and well prepared. The streets of Pau are very dusty and noisy on market days; crowded with drays drawn by poor cows or oxen, dragging their slow length along; the constant bawling of the drivers, who goad these poor docile creatures with long poles armed with a sharp nail, are sights and sounds distressing to the eye and ear of civilization. The public conveyances also, are drawn by horses having a lot of paltry bells, like English sheep bells, jingling at their heads; the drivers carry a long thonged whip, which they think it grand to be incessantly smacking; this all adds to the discord. These bullock drivers from the mountains are the ruffians whose dastardly conduct frequently endangers the lives of the summer visitants going to the Eaux. I quote from a work now before me of a recent French writer on the Pyrenees, who speaks in terms of execration of the fiendish delight manifested by these wretches when, by so placing their drays in the mountain passes, they barely leave room for the passage of a carriage between them and the edge of the precipice, so that the slightest unsteadiness on the part of the horses would instantly precipitate the whole party of visitors into the abyss beneath to be dashed to pieces. He concludes by regretting the absence of those excellent men the "sergens de ville" of Paris, to bring these monsters to their senses. The same remark may be applied to them as was applied by the Sicilian woman to her neighbours the Calabrians, "*Bruta lingua, è bruta gente.*"

(To be continued.)

TEMPERATURE OF THE BODY IN FEVER.

No. III.

By THOMAS WRIGLEY GRIMSHAW, A.B., M.B.Dub.,
PHYSICIAN TO CORN-STREET FEVER HOSPITAL, LECTURER ON MATERIA
MEDICA IN STEVENS' HOSPITAL.

(Concluded.)

At the conclusion of Case 2, I remarked that for a long period the temperature was unusually high, without any other departure from health; I have now to report that this patient returned to the hospital on the January 24th, labouring under typhus fever, of a well-marked character, having the range of temperature which I have found usual in such cases. Can it be possible that the high temperature during her first sojourn in the hospital was caused by the latent fever poison which did not show its presence by other symptoms for above a fortnight afterwards? I cannot think that such was the case; however, it is possible; and the facts observed in this case are important in connexion with the question under discussion.

In the cases given above it will be remarked that they differ from each other in many respects. The cases have been selected from a number of others on account of these very differences. These cases may be classified, as follows:—

- a. Cases at first doubtful, which did not turn out to be typhus.
- b. Simple cases of typhus terminating in recovery.
- c. Simple cases of typhus terminating in death.
- d. Cases of typhus with complications.

Let us now see of what value the thermometer has been in forming an opinion in each of these classes of cases.

Class *a*, includes Cases 2, 6, 7, 8, 10, and 14. In Cases 6 and 10 we have instances where there were many signs which warranted an opinion that fever was not far off, but in these cases the thermometer contraindicated this diagnosis, and must, therefore, in similar cases be considered as a valuable help to the formation of a true opinion. In Cases 7 and 8, the high temperature taken alone would have indicated a much more serious prognosis, than as subsequent events proved, would have been warranted. Case 2 has already been alluded to. In Case 11, the elevation of temperature was not of sufficient height or persistency to warrant any unfavourable opinion; the patient being a painter may have had something to do with the matter, as in a doubtful case, which afterwards proved to be one of lead poisoning, there were considerable and irregular rises in temperature.

With regard to the simple cases of typhus terminating in recovery (Class *b*), we have examples in Cases 1, 9, 12, 17, 18, 19, and 21. In Case 1, we have no spots, therefore the thermometer was of value in helping to determine the true nature of the case. The rise on January 10th, teaches how cautious we should be in using the thermometer as a means of diagnosing a relapse or the advent of a severe sequela. In Case 9, we have the thermometer correcting the indications of the pulse; the former showing a normal temperature on January 9th, 11th, and 13th, although the pulse was much quickened. In Case 12, the thermometer tended to mislead into an opinion that some serious sequela was to be expected, but such did not occur. In Cases 17, 18, 19, and 21, the thermometer agreed with the pulse and all other symptoms in every particular.

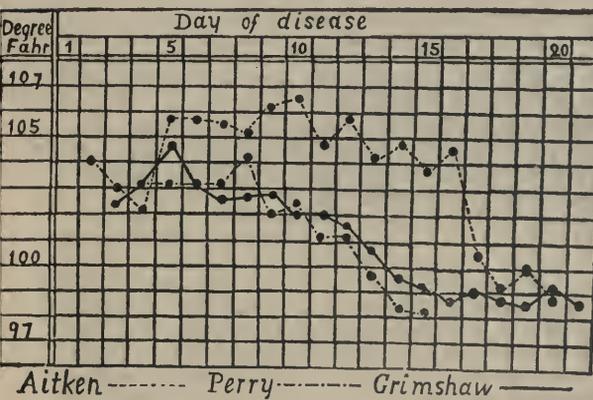

Cases of simple typhus terminating in death (Class *c*) are illustrated by Cases 3, 5, 11, 15, and 16. In the three first of these there was a great fall of temperature before death. It is, I think, clear that these great and sudden falls in temperature, when other symptoms remain unabated, are of most serious import to the safety of the patient. In Cases 15 and 16 there was a rise in temperature before death. These rises I do not consider of such serious import as the sudden falls, as I have noticed many such rises where no serious consequences followed; of course, in conjunction with other dangerous symptoms, they must be considered unfavourable signs. In Case 16, the temperature did not at all accord with the other symptoms, which were of a very bad character.

Concerning complicated cases (Class *d*), of which we have examples in Cases 4, 13, 20, 22, and 23, I may remark that the origin of a complication is always accompanied by a rise in temperature, as noted by Dr. Sydney Ringer (*Lancet*, Dec. 9, 1865), Dr. Aitkin, and others. The increase of heat, however, accompanying a complication does not appear to be commensurate with the importance of the complication; thus, in Case 4, we had a rise of one degree and a half in temperature as a precursor of serious chest complication; whereas, in Case 13, a rise of a degree was only followed by an insignificant disease of the ear, which left no ill-effect behind. In Cases 20, 22, and 23, the complication was bronchitis, which did not appear to alter much the range of temperature as compared with other cases.

Dr. Johnson (*Lancet*, December 9th, 1865) remarks a rise in temperature following a disturbed night. I am glad to be able to confirm his statement, as I have found this to be the case in many instances. On the night of December 30th, there was a great storm in this city, and on the following morning a large number of the patients under observation were found to have an increased temperature, having been kept awake the previous night by the wind.

As to the typical range of temperature of the body in typhus, I am very sorry to have to differ from Dr. Aitken. I consider the range of temperature as given by that gentleman in his excellent work on the "Practice of Phy-

sic," as quite too high for a typical range. I am glad to say I am confirmed in this view by Dr. Robert Perry, in a very valuable and interesting paper read before the Glasgow Medical Society on December 19th, 1865. By selecting twenty-five (of what appeared to me to be typical cases of typhus) from a large number of cases, and taking an average for each day, I have arrived at what I conceive to be a typical morning range of temperature for typhus fever. I subjoin a diagram representing this range, with which I have placed the morning ranges as given by Drs. Aitken and Perry. It will be seen that my line very nearly coincides with that of Dr. Perry:—

I do not at all wish to impeach the accuracy of Dr. Aitken's observations, which appear to have been made with admirable care. I think we must look to the difference in condition or modes of treatment of the patient upon which the observations were made, in order to find out the cause of this discrepancy of results. That there is some great difference in the gravity which typhus assumes in different localities is, I think, shown by the rate of mortality in different hospitals; thus, 20.89 per cent. (Murchison), 14.41 per cent. (Perry), and 8.75 per cent., are the rates of mortality in typhus cases for the London Fever Hospital, Glasgow Royal Infirmary Fever-house, and Cork-street Fever Hospital respectively. The great difference between 20.89 per cent. and 8.75 per cent., can scarcely be attributed to difference in treatment. Perhaps the difference in the range of temperature may be accounted for, by the difference in diet between the English on one hand and the Scotch and Irish on the other, the former being much higher fed than the latter, and having, therefore, more tissue to be burned up, as it were, during a fever, and consequently a higher temperature produced. I merely throw out this as a suggestion, not having any proof of the correctness of the theory. I am afraid the temperature of the body has been relied on too much by some as a symptom of more value, than various others which up to the present we have been accustomed to rely upon as our great guides. Believing thermometric observations to be of considerable value in aiding the formation of an opinion in doubtful cases, and of deep interest from a scientific point of view, I regret that these observations should fall into disrepute owing to their being cried up by those who "ride their hobbies to death." It has been the fate of many valuable instruments to fall into bad repute owing to their deceiving those who relied upon them, to the exclusion of older and more thoroughly tested means of diagnosis in treatment. It is to be hoped that such will not be the case with the thermometer.

In conclusion, I have to return my thanks to my colleagues, Drs. Kennedy and Mason, for their kindness in allowing me to select from among their patients such cases as I considered suitable for thermometric observations; without this courtesy on their part it might have been long before I could have laid these observations before the profession.

RETROSPECT OF THE JOURNALS.

In a leader the *Lancet* reviews the apology of Dr. Edmonds contained in the pamphlet entitled "Millet v. Edmonds." It may be remembered that the latter brought certain charges against Dr. Millet, who was his brother-in-law, in reference to the suspicious death of another Millet who had lived in his house, and subsequently on his death bequeathed to him his property.

On the subject of the examinership at the College of Surgeons, Mr. Lawrence's present position is contrasted with the views expressed by him in former years.

These extracts are from a pamphlet, published in 1826 by no other than Mr. Lawrence. Nevertheless, all the faults which he so signalizes are still rampant, and Mr. Lawrence, at the age of eighty-three, retains the post of examiner, having secured for himself a life interest in that office; thus acting in defiance of the opinions he so well expressed forty years ago, and which are those generally entertained by the profession.

Objection is made to the method of caning boys in the navy on the hands on the ground that the hand becomes so benumbed by the punishment that the boy is unfit for a time for doing duty. He may be even permanently injured.

The St. Pancras Guardians have taken action on the recommendations of the *Lancet* Commission. Thus they have ordered additional chairs, basins, and an extra paid nurse for the female insane patients. The state of the house as to over-crowding is such at present that nothing immediate can be suggested for its relief.

It is well known that "ketchup" for some years past has been made from livers of the cow and pig. Attention is now drawn to the subject in consequence of the analysis by Dr. Hassall of a specimen.

The Southampton Board of Health advertise for a medical officer of health to give up practice, and to be acquainted with chemistry and the microscope for the handsome salary of £150 per annum.

Dr. Hassall proposed the use of a substance to substitute the ordinary meat in the manufacture of soups, beef-tea, &c. The meat is deprived of its water, which constitutes three-fourths of its weight, then dried and pulverized. The "flower of meat," if it will only keep as its inventor promises, will be a great boon to the medical public.

The Cambridge University have agreed to appoint a Professor of Anatomy at £300, a demonstrator at £100, and a Professor of Zoology at £300 per annum: the former of these stipends is too low. It is probable that Professor Humphry will be elected to the vacant chair of anatomy.

The report of the Venereal Committee is published. Its recommendations chiefly point to examination of prostitutes in garrison and seaport towns.

In a paper entitled, "The proofs that Lithotripsy is an eminently successful Operation," Mr. H. Thompson gives the particulars of 24 cases, only one of which was unsuccessful. All these were performed within the year 1865, and are a continuation of nineteen which were performed in the year 1864.

Dr. McClean, in his lecture on Cholera, refers to Dr. Johnston's work on the subject:—

"This able physician has been led to much the same conclusions as to the action of most drugs in cholera as are expressed above. Dr. Johnson puts more faith in the action of purgatives than I can do; for, like every known class of drugs, they have been freely used in India. I sincerely trust that Dr. Johnson may never see so many cases of cholera as I have done; but I cannot help thinking, should it be otherwise, that he will see cause to believe with me that, in a vast majority of cases, there is quite enough purging without artificial aid. Still, for my own part, if again smitten by cholera, let me rather fall into the hands of a purging than an astringing physician—one who thinks he does you service by retaining what Nature is so solicitous to expel from the system."

Hospital Reports.

KING'S COLLEGE HOSPITAL.

CONTRACTION OF THE NECK FROM A BURN.

(Under the care of Mr. WOOD.)

Case 1.—H. S., æt. six years and a half, admitted into King's College Hospital, under Mr. Wood's care, Nov. 7, 1865, with contraction of the neck from burn. The chin was drawn down as low as the tip of the sternum by a tough, hard, raised cicatrix, which extends from the chin to the sternum. On each side of the neck, the integument was drawn in, forming a sulcus. Extending from the right ear to the right mamma, was a broad white cicatrix. Projecting from the symphysis of the jaw, was an apophysis of bone, evidently produced by the pulling of the contracted cicatrized integument. The lad's health was indifferent.

Operation.—Chloroform having been administered, Mr. Wood pinched up the portion of cicatrized skin immediately below the chin. Then pushing the knife through it, he cut downwards over the upper edge of the sternum, making a V-shaped flap. This he dissected upwards over the chin, exposing the apophysis of bone. He sawed it off, and then dissected up the integuments covering the lateral aspects of the neck outwards on each side to the extent of three or four inches. These he drew together by quilled sutures. The head then being thrown back, the V-shaped flap fell into its position, forming a good chin. Sutures were then passed connecting it with the two external flaps. Strips of adhesive plaster and a bandage were applied round the neck and head on to the trunk, confining the arms across the chest. The head was then bandaged to a round pillow placed behind the neck.

The patient was confined in this position until the 18th of November. The upper part of the wound healed by the first intention, but the edges of the external flaps and the tip of the V-shaped flap sloughed. Care was, however, taken in the daily dressing of the case to bring the edges of the wound as closely together as possible. At the present time the wound is healed, with the exception of a small extent situated over the larynx; the delay is caused by a recurrence of small marginal ulcers.

The patient wears a gutta-percha collar to prevent any future contraction.

Remarks.—The wonderful improvement made in the personal appearances of this boy is apparent to all who saw him in the horribly distorted condition which existed before the operation. He possesses now a well formed chin, a perfectly easy motion of the head from side to side, and up and down; but even a greater improvement is to be observed in the features.

CONGENITAL OBLIQUE INGUINAL HERNIA.

Case 2.—W. D., æt. 11, November 10, 1865, was operated upon by Mr. Wood after the method by rectangular pins. This consists shortly of passing pins without a previous incision by the knife. Two pins were inserted in such a manner that their approximation would, without pressure on the cord, be effected by intertwining their ends, and in so doing, with little or no injury to the tissues, would narrow the canal so far as to prevent the exit of the bowel. The pins were removed one week after, and their presence was not followed by anything noticeable further than the almost constant result of this proceeding in Mr. Wood's hands—viz., a speedy and almost painless cure of a condition which is perhaps the most serious which one who is doomed to a life of labour can suffer from.

OBLIQUE INGUINAL HERNIA OF THREE YEARS' DURATION.

Case 3.—W. H., æt. 31, civil engineer, admitted Oct. 12, with a rupture supposed to have been induced by excessive fatigue from riding while acting as one of General

Lee's staff in Virginia. On this occasion Mr. Wood passed wires above and below the pillars of the canal, and removed three on the sixteenth day. After this the sac suppurated, and a drainage seton was passed to get rid of the pus.

On November 9th, he was discharged cured, but as a precaution, he was first supplied with a well-fitting truss.

FIBROUS TUMOUR OF THE HARD PALATE—OPERATION—REMOVAL BY SIR WM. FERGUSSON.

Communicated by Dr. G. de GORREQUER GRIFFITH.

The patient was a young, healthy, and strong-looking man. The tumour had been noticed for some time, but only of late had it taken on rapid growth.

Sir Wm. Fergusson remarked that such tumours as the present were extremely rare; so exceedingly rare that in the entire of his professional experience he had only seen three or four; that the growth in question at first sight seemed to have commenced in the antrum, and to have thence spread until it had perforated the hard palate and projected into the mouth. Viewed as a tumour originating in the antrum, it was curious that it should have projected in no other direction than the mouth; and this fact of the direction which it had taken made Sir William Fergusson entertain doubts as to its being in connexion with the antrum. Again, it was so soft; and yielded such a sensation of fluctuation that to some who examined it, it seemed an abscess pointing towards the mouth. Because of this sensation, Sir Wm. Fergusson made an exploratory puncture into the swelling previous to commencing the incision necessary for its removal; and then, finding his diagnosis correct, proceeded to complete the operation by excising the fibrous mass.

TUMOUR OCCURRING IN THE CALF OF THE LEG—OPERATION—REMOVAL BY SIR WM. FERGUSSON.

The patient was a young, strong, and muscular lad. The tumour involved the calf of the left leg. An exploratory incision was first made in order to make certain of the contents of the swelling. This point being ascertained beyond all doubt, an incision was made along the inside of the calf of the leg, the knife being entered above and then drawn downwards towards the heel; another incision was made in a transverse direction—that is, from the first across the calf to the outer side of the leg. In these the integument was divided, the muscles being left intact.

The morbid mass was very large, about the size of a small brain, and lay beneath the gastrocnemius, that muscle running over it.

It was dissected out; the arteries—a few of which bled—were tied; the wound was sewn up by means of the thread sutures; lint was then placed over the wound; this was retained in its position by the aid of adhesive plaster, and the whole was finally enveloped in the folds of a roller bandage.

The tumour was firmly adherent to the bone—the posterior surface of the tibia—as, indeed, it was on every side; it lay beneath the gastrocnemius, and sent a process deep among the muscles of the back of the leg, then passed between the tibia and fibula, and projected anteriorly, that is through the interosseous membrane, until it came out among the muscles of the fore part of the leg, where it had formed attachments, so that it was fixed in this direction as well as on its other aspects; it was first noticed twelve years since, but especial attention had been directed to it only of late, when it had begun to grow rapidly, to become inconvenient from its bulk, and to impede the movements of the limb in the act of progression; it was distinctly fibrous throughout its structure, except in the centre, where there was a large calcareous mass.

The history of the growth and the condition of the tumour, as manifested during the operation, showed that, if left to itself, it would lead to very serious mischief. Indeed, Sir William Fergusson, before he had

commenced the operation, feared that the tumour was of such a nature as to render its excision impracticable, and that he would consequently be compelled to amputate the limb—amputation, even while the excision was being practised, seeming to be the only step which could be undertaken, because of the manner in which the growth had thrown out branches in all directions. He resolved, however, to give the patient every chance of having his leg preserved to him; and, therefore, with the greatest possible caution, with the utmost care, and by means of tearing somewhat forcibly the tumour from its berth, then cutting its several attachments, was it at length removed.

Proceedings of Societies.

SURGICAL SOCIETY OF IRELAND.

FRIDAY, FEBRUARY 2ND.

Dr. WILMOT, President of the College, in the Chair.

ATHEROMATOUS TUMOUR OF THE SCALP.

PROFESSOR HARGRAVE exhibited a specimen of an atheromatous tumour which he had recently removed from the head of a lady. A microscopic examination of it had been made by Dr. John Barker, who would mention its characters. He thought the specimen worth bringing under the notice of the Society. It seemed to him as if the tumour grew from without inwards. There was a cavity in the centre, and the tumour was enucleated before the cavity was filled up. The lady had four other tumours on the head, but he thought it better to wait some time before removing them, for fear of erysipelas, which was then very prevalent.

Dr. BARKER said—That the tumour presented under microscopic examination nothing at all that would indicate its being of a malignant nature. The epithelial scales were evident, congregated together in clusters, but he did not consider they resembled those usually seen in malignant growths; they were merely epithelial cells, such, for instance, as were to be found on the surface of the mucous membrane. The cholesterine plates were peculiarly characteristic and polarized light beautifully. He did not follow out the examination, being tolerably well convinced that the tumour was not cancer. The fluid part of the tumour was albuminous and rather thick and tenacious, and quite neutral to test paper. He thought it was one of those tumours in which an effort of absorption had gone on to the partial removal of the fluid contents.

Dr. MURNEY stated that he had come in late, and had not heard Dr. Hargrave's description of the tumour, and wished to know if it was one of the ordinary tumours of the scalp? He sometimes dispensed with the knife, and preferred removing them with caustic potash.

Dr. FLEMING said that Dr. Hargrave specially mentioned that it belonged to that class of atheromatous tumour so commonly to be met with in the scalp. He had seen cholesterine repeatedly, not only in encysted tumours in the scalp, but in encysted tumours in other parts of the body. With respect to the caution necessary in the removal of single or multiple atheromatous tumours, he had often removed half a dozen at the very same sitting without any bad result, and he thought it was better, unless some special objection existed, to remove them all at once. These tumours occasionally grew to a large size, and sometimes occurred at the back of the scalp, where they often assumed pedunculated characters. He did not say that the removal of tumours was always without inconvenient consequences, for he had seen erysipelas occasionally supervene, but some members of the Society would remember the removal by Sir Astley Cooper of tumours from the head of George IV., and Sir Astley was apprehensive of erysipelas occurring in that case. As a general rule, however, the supervention of erysipelas was comparatively rare. The contents of these tumours varied very much.

He had seen them of an ink-like character, sometimes suppurating and sometimes transparent. The centre portion was usually transparent.

Mr. RICHARDSON said that erysipelas was not the only unfortunate result that might follow these operations, for he recollected that fatal tetanus supervened after the removal from the scalp of a very small encysted tumour by his late lamented friend, Dr. Mayne, some years before he confined himself to the practice of medicine.

Mr. SYMES observed that it was generally considered an easy matter to remove these tumours, but he had on some occasions found the operation difficult, especially where the bone had become indented, which generally took place when the tumour had existed for a long time. On one occasion he had great difficulty in removing an encysted tumour from a patient in whose frontal bone it had become imbedded. The wound remained open for a long time after the operation, and left some deformity after cicatrization.

Dr. FLEMING said he had reported a case in which a scalp tumour existed almost from birth, and assumed a very large size, much larger than a pigeon's egg, and in that case there was an indentation in the bone commensurate with half the size of the tumour, and the bone was so attenuated that the pulsation of the brain could be seen underneath. Ultimately the case got well, but not for a long time.

Mr. COLLIS said that where the cyst was very adherent, such as was often the case over the eyebrows, it might be advisable to adopt Dr. Murney's mode of treatment; but generally speaking, where tumours occurred over other parts of the skull, if the integuments were divided they could be easily enucleated, and there was no occasion to resort to what would be, in practice, a double operation. If there was any difficulty in getting out the cyst, Dr. Murney's plan of treatment by caustic would have its advantages.

Mr. B. W. RICHARDSON asked Dr. Murney what time the sore left after the potash took to heal?

Dr. MURNEY replied about a few days.

Dr. HARGRAVE—Dr. Fleming had stated that there was little risk of erysipelas after these operations, but he (Dr. Hargrave) thought otherwise, and would mention an instance which occurred to him six years ago. He had taken a tumour from the forehead of a lady who was then in excellent health. He left town for the country, and three days afterwards he was summoned between four and five o'clock in the morning to go and see her, as she was exceedingly ill. She was seized with a most intense attack of diffuse inflammation of the cellular membrane, extending from the scalp to the neck, and it was with difficulty they succeeded in saving her life. It was that which induced him to be quite satisfied with removing one tumour, not wishing a repetition of such a serious disease. There was a question which he wished to ask Dr. Fleming and Mr. Symes in reference to the indentations of the skull of which they spoke. Were the tumours superficial or seated beneath the occipito-frontalis muscle? He never saw the cranium indented by the ordinary encysted sebaceous tumours in the manner spoken of by Mr. Fleming and Mr. Symes.

Mr. SYMES said the tumour to which he referred was seated over the eyebrow; but he could not say whether the occipito-frontalis was over it or not.

Mr. STAPLETON thought the true atheromatous tumour of the scalp never indented the bone, for they were formed superficially, and were merely sebaceous follicles. That were obstructed.

Mr. B. W. RICHARDSON asked Mr. Symes if he ever had an opportunity of verifying by post-mortem examination whether the bone was indented or not by the ordinary encysted sebaceous tumours?

Mr. SYMES said he had not. He had his finger deep in the indentation.

The CHAIRMAN could bear testimony to having seen the bone indented by these tumours.

Dr. FLEMING said that Mr. Stapleton was perfectly right regarding the locality of the tumour; but although the site might be different, the character of the tumours might be the same. They might have one of these atheromatous tumours containing cholesterine in any part of the body unconnected with the skin under the fascia. As to indentation of the skull, he thought he could show the members of the Society many cases where it existed now. He remembered removing one under the temporal aponeurosis, and the indentation was alarming to witness. Not only was the bone indented, but the whole of the bony substance was absorbed, leaving nothing but a membrane through which the brain could be seen.

Mr. STAPLETON—That does not appear to have been an atheromatous tumour.

Dr. FLEMING thought it was. There were not alone epithelial scales, but cholesterine in it.

Mr. WHARTON suspected that those tumours, where the bone was indented, had their origin in the periosteum.

Mr. B. W. RICHARDSON considered the finger may be deceived in these cases. He thought it possible that depressions might be formed in the scalp by the pressure of the tumour, which with circumferential thickening and consolidation would form cavities or cups, and which might lead to the idea they were situated in the bone. He (Mr. R.) merely alluded to the ordinary sebaceous cyst, as he was well aware that the skull may be absorbed from the pressure of other kinds of tumours.

Mr. COLLIS observed that if the periosteum between the bone and the cyst was intact, the indentations could scarcely have been caused by absorption of the bone. If the pressure bore upon the periosteum it would cause its periosteum first, and then that of the bone.

Dr. HARGRAVE brought under the notice of the Society

A CASE OF EXOSTOSIS OF THE FRONTAL BONE.

The disease commenced three years before the admission of the girl who was the subject of it into hospital, and continued to extend until it attained the size which they saw in the cast before them. It then ceased growing. By the cast and drawing which he exhibited they would see that the outer angle of the left eye was considerably depressed. This interfered with the elevation of the upper lid, but by pressing the under lid with her finger she could use the eye. In December, last year, the tumour was removed. The integument and the periosteum were dissected off it, and then they found the tumour implicating the frontal bone; the tumour was extremely hard, and it took a considerable time to detach it. It was removed, leaving the bone quite smooth. There was a projection over the eyebrow, which was removed by a chisel, so that the arch of the eyebrow was preserved, but there was a small exostotic point just at the orbit, which was allowed to remain. Two days after the operation the girl was attacked by erysipelas, which extended from the left to the right side of the face. It got well under the use of mercurial ointment, bark, and chlorate of potash. She progressed very satisfactorily, but there was a large discharge of perfectly healthy pus. A few days after the operation she suffered from ptosis; she had now, however, recovered command of the upper eyelid. There was extreme œdema of the conjunctiva of the upper lid. Dr. Jacob advised that it should be laid open from end to end, which was done freely, and nothing but serum escaped. They were now applying a strong solution of nitrate of silver, and under its use the œdema of the conjunctiva was rapidly going down. The growth had been examined under the microscope by Dr. John Barker, who said its anatomical structure was the same as healthy bone. It was just a month since the operation.

Mr. STAPLETON asked if there was any bleeding from the bone?

Dr. HARGRAVE replied in the negative, and in reply to a further question said—It neither threw up granulations nor did it exfoliate. He did think that there might be

exfoliation, but there was not the slightest appearance of it as yet.

Mr. COLLIS said that, a year ago, in performing section of the elbow-joint, he met with a case of ivory hardness of the bone from chronic osteitis, and although it took him a long time to cut through the bone, so long that he had to rest in the middle of the operation, yet in that case there was no exfoliation, and the case progressed to cure as rapidly as if the osteitis had not existed. There was no reason why this kind of bone should not heal readily; for although it was exceedingly dense, yet when examined under the microscope it would be seen to be amply supplied by bloodvessels. In this case there were plenty, and therefore he did not see why it should not heal.

Dr. BARKER observed that he noticed during the operation the great difficulty experienced in sawing through the bone. The density of the bone was very apparent, and presented when freshly taken off, in some parts, but not in all, a faint trace of blood infiltrated. In the deeper portions of the bone the canaliculi were seen very well developed, but in other parts of it they were very few in number, and the bone cells seemed to have been gradually filled up, and the canaliculi could not be traced. Mr. Hargrave would bear him out in saying that the bone was softest in its deeper portions.

Mr. HARGRAVE—Yes.

Dr. BARKER—This was a very excellent example of pure exostosis. This was a disease that frequently occurred in the lower animals, and in birds especially, a sort of ivory deposit occupied the place of pure bone, and very frequently was found in the breasts and legs of fowl.

Mr. CROLY said he had the opportunity of assisting Mr. Hargrave in performing this operation. Mr. Hargrave's hand got tired from the great hardness of the bone, and he (Mr. Croly) assisted him in completing the operation, and saved through a great portion of the tumour. The sections of bone that were removed were extremely vascular, and they had to use the sponge several times to enable them to see what they were doing. The bone was perfectly pink, and it projected from the orbit.

Mr. HARGRAVE said it was quite possible that Mr. Croly might have seen blood coming from the bone, though it was not observed by him. When he removed the tumour its base seemed to be free from blood.

Mr. STAPLETON said that in cases of this kind within his own experience, where he had taken a long time to saw through the bone, he had seen a great deal of hæmorrhage.

Mr. EDWARD HAMILTON—As to the subject of hæmorrhage from tumours on the frontal bone, a case occurred in his practice in which hæmorrhage was most profuse and alarming. As soon as they made a section of the tumour the blood flowed in such quantity that they were obliged to desist from the operation and employ every means they could resort to to stop the hæmorrhage, and even afterwards the bleeding recurred.

Mr. CROLY stated his impression was, that the surface of the tumour was vascular; for although there was of course bleeding from the flaps, they were held carefully up by the students, and notwithstanding that and the temporal artery being pressed upon, he had to use the sponge, and his impression was that the bone was bleeding from a number of points.

Dr. BARKER observed that when he said that a portion of the tumour was softer, he meant that it was relatively softer, but it was still very hard. They would see in the section before them that the pink portion was still preserved, while the other part was of an ivory character. One portion was devoid of all vascularity and apparently harder than the other.

Dr. MURNEY wished to ask Mr. Hargrave, did he think this tumour would ultimately grow again? He thought it might probably do so. He saw a tumour of this kind removed by the late Dr. Bellingham from the same place. It recurred, pressed the brain, and destroyed the patient.

Mr. HARGRAVE said Dr. Murney asked would the tumour

return or not? That he (Mr. Hargrave) was not prepared to say. Dr. Murney thought it might return and compress the brain. Now, if ever an innocuous tumour presented itself to the surgeon it was this one. The girl was perfectly healthy, never had a fit of any kind, and had perfect vision, although the pupil was somewhat dilated. Dr. Murney thought operative interference should not have been resorted to, but he differed from him. The patient was a remarkably handsome girl. She came up to town expressly to have the operation performed. Her family were most anxious to have the deformity removed, and this had been done so that scarcely any mark would be left on her forehead. The girl was sent to him expressly to have the operation performed, and he thought if there ever was a case calling for interference it was hers. The case was going on satisfactorily, with the exception of the œdema of the conjunctiva. The eye had partly receded, and she had great power over the superior lid, which she could not raise before.

FIBRO-CELLULAR TUMOUR.

Mr. EDWARD HAMILTON wished to bring under the notice of the Society a tumour which presented some peculiar features, and which he removed from the leg of a man in hospital a few days ago. It was situated superficial to the gastrocnemius muscle, between it and the skin. On examining the tumour, it conveyed a remarkable feel of elasticity, so as to lead to the supposition that it was an encysted tumour, and contained fluid. He had seldom felt the feeling of elasticity give rise, so to speak, to so distinct a sense of fluctuation. The tumour was perfectly movable under the skin, and the skin movable over it. There was no discoloration of the integument on the surface, save some trifling redness caused by the irritation of the rubbing of the projecting portion of the tumour against the man's trousers. The history he gave was, that the tumour had existed for the last seven years, and he (Mr. Hamilton) remembered examining the tumour two years ago, when he proposed its removal, to which, however, the man objected, as it did not cause him any inconvenience at that time. It commenced as a small point, like a pea, under the skin, and perfectly movable. The man appeared to be in rude health. Within the last year the tumour continued to grow rather rapidly, and hence the man was anxious to have it removed. On making an incision over the tumour it turned out with the greatest facility—indeed, much more easily than he had anticipated. A section of having been subsequently made it presented a curious appearance of fibres arranged in circles, like what had been termed concentric globes. Under the microscope it had the appearance of a simple fibro-cellular tumour, but Dr. Symes drew his attention to some cells which existed in the field of the microscope, which and larger than the others and evidently polynucleated. However, taking into consideration the length of time the tumour had existed, and that there was no glandular contamination, he thought it was a benign tumour.

Mr. COLLIS—What was the thickness of the skin over it?

Mr. HAMILTON—Merely the natural thickness of skin.

Dr. FLEMING said he had an opportunity of seeing this tumour before operation, and he agreed with Mr. Hamilton as to the deceptive character of fluctuation it presented. It was turned out with the greatest facility like those in the scalp. The extreme elasticity of the tumour was remarkable, and the feeling of fluctuation might have induced a surgeon to test it, which would have done no harm, but might cause him to be accused of ignorance as to its pathology.

Mr. SYMES said he had examined the tumour after its removal, and he thought it a fibro-cellular tumour. It resembles in structure the fibro-cellular tumours described in Mr. Paget's work.

Mr. COLLIS—As to the microscopic appearances, the characters of the majority of the cells must be taken into consideration, and not the peculiarities of a few isolated ones. In a tumour of this kind there might be a great variety of cells.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, FEB. 6TH, 1866.

Dr. PEACOCK, President.

Dr. Cobbold, Mr. Jessop, and Mr. Watts, were elected members of the Society.

Dr. DICKINSON and Mr. SIBLEY read a report on Dr. Crisp's specimen of cattle plague, relating chiefly to the characters of the cutaneous eruption. The reporters believed that the eruption is not constant. Its characters were minutely described, and referred to altered epithelial formation.

Dr. FAGGE exhibited a specimen, showing the Abnormal Position of the Ureter in front of the Womb, an abnormality not previously described. Dr. Fagge remarked that in such a case a doubt might be thrown on the report of a post-mortem examination. Therefore it is well that the occasional existence of this anomaly should be known.

Mr. ADAMS showed a Loose Cartilage removed from the Knee-joint by the Subcutaneous Method. Mr. Adams also observed on the microscopic appearance of this cartilage, which was in a condition of incipient ossification or calcification.

Mr. BRYANT brought forward two cases of

RUPTURED FEMORAL ARTERY,

one from disease, the other from accident. In the former case the patient, aged 75, was admitted dying from disease of the heart and arteries. One day he complained of pain in the thigh, and a pulsating tumour was found in the site of Hunter's canal. The artery was tied above the tumour; it was atheromatous, and yielded with a crackling sensation. All pain ceased in the limb. The ligature did not separate; but the man gradually sank, and died three weeks afterwards. The ligature was found in position. The whole vessel was blocked up nearly as far as the aneurismal sac, which was composed of the muscles and soft parts of the thigh.

In the other case the patient had rupture of the popliteal artery from accident. The limb became gangrenous about a fortnight afterwards. Secondary hæmorrhage occurred, for which at first the femoral and next the external iliac artery was tied. He still remains in a very critical state, four days after the last operation. On examination of the leg, the anterior crucial ligament was ruptured, and the posterior was injured. The popliteal artery was completely ruptured, and its ends retracted about an inch. The posterior aspect of the vein showed some traces of rupture, corresponding to the arterial lesion.

Mr. DE MORGAN showed a patient in whom he had removed a recurrent tumour from the orbit, after the removal of the globe for a disease presumed to be malignant. The tumour rapidly recurred, distended the lids, and spread on the face four inches in each direction. It was removed, freely cauterized, and stuffed with chloride of zinc (Dr. Fell's paste). After its excision, the parts covering the bones of the orbit, together with these bones, came away, and a healthy surface was left exposed. The globe of the eye, which had been removed, was examined, and it was found that masses of malignant disease were disseminated around the optic nerve, and some of the germs of cancer had been probably left behind. The patient remained well till a few months afterwards, when several small portions sprouted again, and were destroyed with chloride of zinc. The patient now remains perfectly well. The operation was performed in the year 1864. This case affords strong support to the theory which regards cancer as, in its commencement, a mere local disease, which is curable by a very complete removal.

Mr. TOYNBEE exhibited a specimen showing the presence of Hairs in the Mastoid Cells.

Mr. TOYNBEE also exhibited a specimen of Disarticulation of the Stapes from the Incus.

Mr. HINTON showed a similar specimen from a patient who was not deaf.

Mr. HINTON likewise showed an Exfoliation of the Tympanic Ring from a child some months after scarlet fever.

Dr. WEBER of Berlin, sent some specimens showing the possibility of injecting fluids into the internal ear through the Eustachian tube, and thus refuting the assertion of Dr. Kramer that this is impossible.

Dr. BARRETT showed a specimen of Multilocular Cyst, presumed to be of the Ovary, which was operated on, and it was found that after the severance of some adhesions to the omentum, no pedicle existed. This was probably a degenerated ovum, which had not been impregnated.

Dr. CONWAY EVANS exhibited a specimen of Aneurism of the Innominate Artery, with fracture of the sternal end of the clavicle. The patient was admitted into King's College Hospital about a year after the accident, with a pulsating tumour reaching from the parotid region to the third rib, and extending over to the opposite side. The symptoms were comparatively slight. The diagnosis made by the sphygmograph was that the subclavian was unaffected. The man died from rupture of the artery through the skin, the tumour having greatly collapsed. It remained questionable whether the aneurism had been caused by the fracture, or had previously existed, and had been injured in the fracture.

Mr. H. SMITH showed the parts removed in Excision of the Knee-joint for unfavourable ankylosis, with much pain, after old disease of the knee. The case went on particularly well, and the patient was able to get up and walk on crutches in about a month, with a perfectly stiff knee. The ankylosis appeared to be bony, at least to a great extent. Very free incisions had been made, one of which still remained in the condition of a small sinus.

Mr. Z. LAURENCE showed a healthy Lachrymal Gland extirpated in a case of injury from caustic soda, which had destroyed the excretory apparatus (canaliculi and puncta). An attempt was made to restore the ducts; but, as this was found impossible, the lachrymal gland was removed. The watering of the eye ceased, nor was there any undue dryness of the eye.

Mr. LAURENCE also showed a case of Detachment of the Retina.

Dr. DUCKWORTH showed specimens of partial Obstruction of the Ileum from the development of four fibrous tumours in the coats of the intestine.

Dr. DUCKWORTH also showed a case in which the Gall-duct was obstructed by a Calculus.

Mr. HUTCHINSON showed a portrait of a patient with congenital Absence of the Upper Extremities.

Mr. HUTCHINSON also showed a specimen of Dwarfing of the Radius from supposed injury to the bone in separation of the epiphysis.

Mr. BROOKE exhibited a specimen of Thickening of the Intestine in an old hernial sac, in which it seemed that the intestine was irreducible, and a truss had been worn with so much pressure that the skin had been ulcerated.

JUNIOR SURGICAL SOCIETY OF IRELAND.

Dr. MAPOTHER in the Chair.

THE CHAIRMAN called on Mr. Scott to read his paper on "Anthrax," which was highly instructive, many valuable suggestions being thrown out during the debate as regards the treatment of this disease.

Mr. MARSHALL read a paper on "Opium," the various specimens of which he exhibited to the Society.

Mr. MACARTNY reported an interesting case of "Hysteria simulating Hip-joint Disease," which had come under his notice during the week at one of the hospitals.

The CHAIRMAN next called on Mr. Ridley to read his paper on "Anatomy, Muscular Anomaly." The supra-costalis muscle found present on both sides of a tolerably well-developed old female subject, arising from lower border of third rib, three and a half inches from outer border of sternum; on the right side it was narrower and thicker than on the left, measuring three inches in length, three-

quarters of an inch in breadth, and one-eighth of an inch in thickness; from its place of origin it extended vertically upwards, lying on the serratus magnus musculo and partly in front of long respiratory nerve of Bell, then ascending behind the axillary vein and subclavian muscle. It was inserted on the right side into the first rib, above the origin of the first indigitation of the serratus magnus muscle, but on the left side it cleared this bone, and expanding, was inserted into the deep cervical fascia in the posterior inferior triangle of the neck; it lay considerably external to the origin of the pectoralis minor, from which it was separated by a strong aponeurotic expansion of the deep axillary fascia, and its insertion was placed internal to scalenus anticus muscle.

The CHAIRMAN, having drawn the attention of the members present to the subjects brought under their notice that evening, congratulated them on the successful way the Society was working. Shortly afterwards the meeting adjourned to February 23rd.

Foreign Medical Literature.

V. ON THORACIC AND ABDOMINAL RESPIRATION, PECULIAR TO, SIGHING AND YAWNING.

By Professor Dr. F. C. DONDERS.

Translated from the *Nederlandsch Archief voor Genees- en Natuurkunde*, 1e Deel, 2e Afl. Utrecht, 1864, for THE MEDICAL PRESS AND CIRCULAR.

By WILLIAM DANIEL MOORE, M.D. Dub., M.R.I.A.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS, OF THE NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

It is well known that the ordinary quiet respiration is performed in man chiefly by the diaphragm, in woman by the scaleni and intercostal muscles. In connexion herewith, we see the movements strongest in man in the abdomen, in woman in the upper part of the thorax. But on the deepest possible inspiration, to determine the vital capacity, the movement takes in man, too, the form of thoracic respiration; the thorax is elevated, above especially it is expanded while the abdomen is even flattened, as this cavity, by the ascent of the diaphragm, obtains room superiorly for its viscera. For this reason it has been stated (*conf.* for example Ludwig, *Physiologie*, B. II., p. 487), that in deep inspiration the form of movement is the same in man and woman.

I formerly pointed out (*Handbuch der Physiologie*, 2nd edition, Vol. i., p. 400), that preserving the type of thoracic respiration, we can take in very much air.

This takes place, when we bring the diaphragm with all our might into action, whereby it descends low into the abdomen, causing the abdominal viscera, and with them at the same time the elastic ribs and cartilages of the ribs, to yield anteriorly and externally, and to expand the inferior part of the thorax.

So far as I can satisfy myself, the diaphragm alone is active in this: the lower part of the chest is rather expanded than elevated, and the upper portion undergoes some movement and dilatation only so far, as, in consequence of the expansion of the inferior opening of the thorax, the whole thoracic wall acquires another inclination.

I formerly also determined the vital capacity proper to this type of abdominal respiration, and found that in myself it was only from 300 to 500 cubic centimètres less, than in thoracic respiration.

This movement I earlier thought possible only by a definite act of the will, and I then believed it also to be somewhat constrained and unnatural. The great majority of men have, in fact, a tendency, when they wish to inspire deeply, to employ thoracic respiration, and even, if they had already made an ordinary inspiration with abdominal breath-

ing, to give up this and to adopt thoracic respiration. I have now found, that abdominal inspiration also occurs involuntarily, automatically, and, consequently, is represented in a definite condition of the central nervous system. *A deep abdominal respiration, in fact, characterises yawning, while a deep thoracic respiration accompanies sighing.* Two different forms of movement are thus excited, in connexion with two different psychical states, which we may suppose to act as stimuli on distinct nerve-centres. Besides these psychical conditions, too, the idea developed from the contemplation of similar movements in others, easily excites them both. Nay, the idea alone is often sufficient to produce these effects, so that many of my readers will be able forthwith to convince themselves of the correctness of my statement: that thoracic inspiration is connected with sighing, abdominal inspiration with yawning. To these also other movements are added, in sighing limited to raising of the palate and wide opening of the chordæ vocales, while yawning is preceded by contraction of the transverse muscle and of the depressor of the ala nasi, and is connected with wide opening of the jaws, dilatation of the oral slit, expansion of the soft palate, and is sometimes combined with contraction of the internal muscles of the ear, giving rise to a peculiar buzzing in that organ. That the shoulders and arms are at the same time also brought into motion is well known. I have, moreover, observed, that the commencement of sighing, and especially a voluntary rather deep thoracic inspiration, sometimes passes into involuntary yawning, with abdominal respiration. Less methodical is the transition of abdominal respiration into thoracic respiration, when, that is to say, the former has attained a certain height: we feel, that then another type of movement is required, and we are inclined, not to say compelled, to expire partially before producing the new type.

I have already spoken of abdominal inspiration as a voluntary movement. Many have, however, great difficulty in effecting it strongly. It succeeds best when one is made to inspire quietly in the ordinary manner, and then to continue that form of movement, as far as possible, particularly suiting the action to the word.

If some now pass over into thoracic breathing, they soon learn to avoid this, especially when they have once felt, what takes place in yawning. Nevertheless they do not yet so rapidly attain the full vital capacity. In the first place practice seems here to accomplish something; I formerly obtained only 3500, now I have reached 3750 cubic centimètres, while my vital capacity in thoracic respiration has remained at 3900. In ten consecutive experiments, for both, I obtained scarcely more than 50 cubic centimètres difference. In the second place the tension of the abdominal muscles is to be taken into account. Strong young people with flat abdomens have in abdominal respiration a comparatively slight vital capacity. In the sitting position, leaning somewhat forward, such persons can, by relaxing the abdominal muscles, attain rather more, while, *vice versa*, in corpulent individuals the standing position is more advantageous. The explanation of the fact that in these latter the vital capacity of abdominal respiration is greater, is to be found in the greater compass of the abdomen, whose contents on equal, and still more on proportionate extension of the wall, must increase more decidedly, and moreover probably in the greater extensibility of the thinner layers; in connexion herewith abdominal respiration seems in general to become more prominent with the advance of years, and the vital capacity thereof to increase.

On the vital capacity in thoracic respiration position has much less influence, while it makes room enough for the abdominal viscera. Therefore the vital capacity is also much less modified by the contents of the stomach and intestinal canal, which have a very essential influence upon it in abdominal respiration.

I have also tried how much air can be expired after yawning and sighing excited by an idea, and found it only

from 100 to 200 cubic centimètres less than the respective vital capacities.

If we wish to employ force with the upper extremities, or prepare to defend ourselves, we take in air by thoracic inspiration, whereby the chest becomes more rigidly expanded and affords a better fixed point for the muscles arising from it. In order to exert pressure upon the abdominal viscera we make a moderate inspiration, which I should call mixed. In this case pure abdominal inspiration is, notwithstanding the more powerful descent of the diaphragm, less advantageous, probably because the points of attachment of the abdominal muscles superiorly to the ribs, whence they arise, are not sufficiently fixed. In order to speak vigorously, to sing or to cry, the chest must be filled with air above. Expiration can then take place under the greatest tension. We see this in good singers and orators. The maximum of the expiratory pressure is also greater after thoracic than after abdominal inspiration. In myself I find for the former 86 (3.38582"), for the latter 71 mm. (2.79527") of mercury. The negative pressure, in the effort at a fully-forced inspiration, amounts, in the former to 64 (2.51968"), in the latter to 62 mm. (2.44094"). These experiments were made with a manometer, through an elastic tube brought into connexion with one of the nostrils, while the other was closed: the action of the mouth must be excluded. Balancing of the quicksilver was thereby avoided. I, moreover, endeavoured to determine the influence of the two forms of inspiration upon the circulation of the blood by means of the sphygmograph, but found it impossible, although I had my arm firmly fixed in Vierordt's apparatus, to keep it in forced inspiration quiet enough, to place any confidence in the direction of the curve. The slightest movement produces a considerable deviation. These experiments had no other results than to make me too very sceptical as to the results respecting the influence of respiration upon the sphygmographical curve, in their entirety, published by Marey.*

In women I have as yet made no investigations upon the two types of respiration. I have only satisfied myself that they exist in them.

PRIMITIVE FALSE ANEURISM OF THE FEMORAL ARTERY:

LIGATURE BY ANEL'S METHOD: OPENING OF THE SAC: SERIOUS UNFORESEEN EVENTS: CURE.

By Dr. NOTTA, Surgeon to the Hospital of Lisieux, &c.

Translated from *Union Médicale* for THE MEDICAL PRESS AND CIRCULAR.

By GEORGE BOLSTER, L.R.C.S.Ed., L.K.Q.C.P.I., of Woodlawn, Newcastle West, Limerick.

BRUNET, a farmer, aged 50 years, thin but healthy, received, on the 20th May, 1865, a kick from a horse on the inner part of the right thigh, at a point corresponding to the junction of its inferior and middle third. Immediately a tumour as large as the clenched hand developed itself on the surface of the part contused. At the end of ten minutes the patient was affected with syncope; after a short time he recovered, and was removed to his own house, about nine miles from Lisieux. The next day Dr. Levillain, who had been called when the accident occurred, saw him again. He found the tumour a little painful and without pulsation. He felt the posterior tibial artery pulsating, and also the dorsal artery of the foot (*la pédieuse*). (Patient confined to bed, bladders filled with ice applied to the tumour.) During the two following days patient remained in the same state. On the 24th May the patient, whilst making an effort in bed to place himself upon the bed-pan, felt a most acute pain

* *Physiologie médicale de la circulation du sang*, &c. Paris 1863, pp. 287—292.

in the thigh, and in a few moments the tumour became twice as large as before.

Dr. Levillain, having been again called, sought for pulsation in the tibial and dorsal arteries of the foot, but found none. (Ice applications continued as before.)

May 26th: (Edema of the leg and thigh manifests itself; the tumour appears to increase, and at its middle part feels softer. On the 28th of May I see the patient for the first time; he is apyretic; pulse regular; stethoscopic sounds, and pulsations of the heart normal. All the organic functions act with regularity. The right thigh is enormously swollen. At its internal part there is a tumour three times as large as the hand clenched, livid, and presenting at its most sloping parts blackish plates, evidently pointing out the traces of effused blood in the subcutaneous cellular tissue. At its most salient or prominent point a parchment-like excoriation may be observed, the impression of the rim of the horse shoe. The circumference of the tumour is ill defined, and its margin is imperceptibly continuous with the general tumefaction of the thigh. The circumference is hard; in the centre there is a sensation of fluctuation, where also pulsation and expansive motion isochronous with the pulse at the wrist may be perceived. When the femoral artery is compressed these pulsations cease, and the tumour becomes diminished in a very appreciable manner; yet this diminution is not so evident as one might suppose at first sight. Upon auscultation, a *bruit de souffle* may be clearly heard corresponding with the arterial diastole, and the expansive movements of the tumour itself. If the stethoscope be applied over the femoral artery on a plane with the crural arch, the *bruit de souffle* may be heard louder and more distinctly than at the centre of the tumour.

Auscultation at the same point of the femoral artery of the sound limb will give no *bruit de souffle*. A little painful on pressure, this tumour has been the seat of spontaneous pains, which were very sharp on the 24th, but afterwards considerably diminished, and now there is scarcely any. The knee is swelled; the patella is lifted up by the effusion of liquid, which has no communication with the tumour. The leg is œdematous; its temperature to the hand appears to be the same as that of the sound leg. It is impossible to perceive any pulsation in the dorsal artery of the foot (*la pédieuse*), and also in the posterior tibial. On the 29th of May, with the kind and valuable assistance of Doctors Quesnel, Levillain, and Toutain, I placed a ligature on the femoral artery on a level with the top of the triangle of Scarpa. The incision encroached a little upon the circumference of the base of the tumour. The cellular tissue surrounding the muscles is infiltrated with blood; nevertheless, the operation was easily performed. The vessel is laid bare, and denuded to a small extent, about five millimètres (*the one-fifth of an English inch*), and appears quite sound. A strong ligature is applied; one end of which is cut close to the knot, and the other fixed outside the wound. A piece of charpie spread with cerate, about 15 millimètres in size, served to prevent reunion of the wound by the first intention, from the vessel to the skin. The rest of the wound is reunited by means of the twisted suture. (Lukewarm cataplasms lightly applied to the tumour, and hot bottles around the limb).

31st May: On the day of the operation the patient experienced intense pain in the limb, and much agitation during the night. Next day the same state continued, with delirium, which yielded to a very strong opiate draught. To-day the patient is calm and free from fever; he complains of a little pain in the limb. The wound is suppurating in the course of the ligature. The pus is of good quality. There is no reunion at the points of suture; the leg is hot and œdematous. The tumour formed by the aneurism feels hard in some parts and fluctuating in others. It appears to have diminished; no pulsation can be perceived in it. At its centre the little eschar produced by the impression of the horse-shoe begins to be detached. (Cold cataplasms moistened with

saturnine lotion applied over the tumour; the wound over the ligature is dressed with charpie soaked in alcoholic tincture of walnut leaves.)

3rd June: Patient in same state as on the 31st ult. On applying the stethoscope over the femoral artery in the groin we could not distinguish any *bruit de souffle* again.

7th June: No fever; wound looks well. The tumour fluctuates less, and is diminished. The eschar at its centre has fallen off, and at the bottom of the wound a clot of dark blood of from seven to eight millimètres in diameter (three and a-quarter English inches) may be perceived. A little sero-sanguineous matter is being discharged from the wound; the leg is resting on its outer side; and along the course of the fibula, where the pressure of the limb on the cushions is greatest, a sphacelated band of three centimètres broad (about one and a quarter English inch), and from fifteen to twenty centimètres long (six to eight English inches) may be perceived. We now change the position of the limb, and recommend that care be taken that the leg does not rest too long upon the cushions on a level with the same points. (Cataplasms discontinued; compresses soaked in alcohol applied over the aneurismal tumour.)

21st June: The ligature of the artery came away yesterday; the wound is almost entirely cicatrized; the eschar of the leg is detached; it includes the entire thickness of the skin. The tendon of the peroneus longus lateralis is exposed, as well as a part of that muscle itself. The foot is less swelled; the aneurismal tumour has diminished to almost half of its original size. The orifice of the wound, which is in the centre, is at least fifteen millimètres in diameter (one four-fifths of an English inch), and at the bottom at a depth of one centimètre (two-fifths of an English inch), some dark clots may yet be perceived. There is no suppuration, but an oozing of blackish blood. The tumour is still a little soft at its centre, and feels as if it still contained some fluid. (Both wounds are dressed with charpie soaked in tincture of walnut leaves). General state good; appetite good; digestion good; little fever.

30th: Within the last three days the aneurismal sac has diminished. A large quantity of dark blood mixed with pus is discharged from the wound. On introducing the finger we immediately arrive at a large circuitous subcutaneous cavity, then we enter a deep canal in the muscles close to the femur, which is not denuded. There is a little swelling in the popliteal space. Following the axis of the limb I made a large incision of ten centimètres long (four English inches); then this wound was dressed with charpie soaked in tincture of walnut leaves. A tent impregnated with the same is introduced into the canal which runs close to the femur.

10th July: The tendon of the peroneus longus lateralis has exfoliated, and is cast off. The aneurismal wound looks well. After five days an enormous fibrous clot, which filled the aneurismal cavity, is detached, and was extracted from the wound. Since then suppuration has very much diminished, and cicatrization proceeds rapidly. General state good. In the beginning of September the wounds were closed, and the patient able to sit up.

On the 1st of October he began to walk and support himself upon the limb. The movements of the articulations are very free. There is a little œdema of the ankle-joint. On the aneurismal surface there is a long depressed cicatrix adhering to the bone.

Remarks.—In the history of this case many important and peculiar circumstances present themselves to the mind. In the first place, the formation of aneurism in this way is of very rare occurrence. A man receives a kick from a horse at the inner part of the thigh. All the soft parts, muscles, and femoral arteries comprised between the femur, which is not fractured, and the extremity of the horse-shoe, are divided. The skin alone, thanks to its elasticity, escapes unbroken, yet at this point it is so contused that after a short time it becomes stricken with sphacelus. Without dwelling further on the development

of the tumour which I have already sufficiently described, we arrive at the chief point of consideration—that is to say, the treatment. When I saw the patient for the first time, the tumour was so voluminous, it increased so rapidly, and the limb was so much tumefied, that I considered it necessary to act, and to act in a manner at once the most prompt and efficacious. Three ways at once present themselves for consideration:—

1st. Compression of the artery in the groin.

2nd. Opening the sac and placing a ligature on the proximal and distal ends of the artery.

3rd and lastly, placing a ligature upon the artery above the aneurism, after the method of Anel. Compression could not be borne by the patient. I tried several times to compress the artery in the groin with the finger, and at each time the patient complained of intense pain. Besides, this region was now infiltrated with blood, and much swollen. Now, under such conditions, compression would infallibly promote gangrene of the tissues, or at least, suppurative inflammation of them. Moreover, if the preceding considerations had not caused me to reject such treatment, I should not have employed it with this patient, not that I for a moment question, or refuse to acknowledge the positive efficiency of the treatment by compression, or that in a great number of cases it possesses a marked superiority over other means employed for the cure of aneurism, but I regard it as altogether impracticable in country practice. When one is many miles away from his patient, whom he can only see at rare intervals, how can he attend to compression? How can he practise it in a methodical and skilful manner? and I speak here only of compression with the compressing instrument, for nobody could dream for a moment of digital compression under such circumstances. Compression, then, being out of the question, nothing more remained but to open the sac, or tie the artery after Anel's method. The opening of the sac in this case appeared to us to be positively contraindicated.

In fact, the artery was situated too deeply; it would be necessary to look for it at the point where it passes round the femur to become the popliteal (“*fémorale postérieure*”). Would any one feel certain of finding both ends of the vessel in this immense focus, in the midst of a mass of dead and disorganized animal matter? Would not one run the risk of opening the femoral vein in the course of these searches? In short, the excoriation which existed at the summit of the aneurismal tumour appeared to be superficial, and nothing would lead one to suppose for a moment that the aneurism should necessarily give way at this particular point. We would then take away all possible chances of resorption of the tumour, and place in contact with the air a large cavity infiltrated with blood, and the inflammation whereof would spread to remote parts and cause the death of the patient. Anel's mode of operation, which we preferred, enabled us to avoid some of the dangers of the old method, and the results happily confirmed our anticipations. Resorption commenced to set in, the effusion of the knee-joint disappeared; and, when the aneurismal cavity became exposed by the casting off of the eschar, and that we were obliged to cut into the aneurismal sac, the tumour had already become much diminished, the neighbouring parts were less exposed to the spread of inflammation, and we had a suppurating surface much less extensive than we should have had at first. Dressing the wounds with alcohol or tincture of walnut leaves, which, I consider, all the same, appears to have had in this case a most happy influence in promoting the cicatrization of the aneurismal cavity, preventing the putrid ramolissement of the effused blood, stimulating the wound, and, at the same time, promoting a healthy suppuration and the development of fleshy granulations, which have already filled up the immense void formed in the middle of the soft parts of the thigh. I think it still useful to direct attention to the gangrene which became developed along the course of the fibula during the few first days after the application of the ligature. This sphacelus,

owing to the whole weight of the limb constantly bearing on the same points where the capillary circulation was diminished by the effect of the ligature, and by the action of the aneurismal tumour itself might have been, I think, avoided if we had taken the precaution of changing the position of the limb often during the day. Be that as it may, this accident has not had any influence upon the happy issue of the disease, and, our patient now perfectly cured, has recovered the use of his limb.

Reviews.

LECTURES ON CLINICAL MEDICINE. By A. TROUSSEAU. Translated and Edited, with Notes and Appendices, by P. VICTOR BAZIRE, M.D. Lond. and Paris. Part I. Pp. 276. London. Robert Hardwicke. 1866.

THE great reputation of Professor Trousseau as a practitioner and teacher of medicine in all its branches, and more particularly in those relating to the nervous system, renders the present appearance of his Clinical Lectures in an English form particularly welcome. These discourses are the more useful to the British practitioner, because they are eminently practical, the aim of Professor Trousseau having always been to cure or alleviate disease, as well as to describe it.

The contents of this first Part relate entirely to disease of the nervous system. A few of the Lectures may be already familiar to our readers, as they formed part of the first edition of the French original, but most of them are devoted to perfectly novel subjects, among others, those on Aphasia (loss of speech), Progressive Locomotor Ataxy, and Glosso-Laryngeal Paralysis.

The Lecture on Aphasia, or, in the author's own words, on “the loss of the faculty of expressing one's thoughts by speech, and in most cases, also, by writing and by gestures,” may be justly regarded as a model of clinical teaching. Never, we believe, has the peculiar talent, which Professor Trousseau possesses, of clearness of exposition, logical reasoning; and accurate observation, been shown to greater advantage. The symptomatic history of this singular affection, its varieties (whether accompanied or not by hemiplegia, and the side of the body which is affected), the post-mortem appearances found in several fatal cases, the conclusions deducible therefrom as regards the localization of special faculties in particular and determinate parts of the brain, and the psychological aspect of the question, every point is examined and discussed in all its bearings and details. We would specially direct attention, therefore, to this able *exposé* of a most interesting subject, interesting alike to the physician and the psychologist. Perhaps no cases of this affection are so striking or so interesting as those in which the aphasia is transitory, of a few days' duration only, and is unaccompanied by paralysis. The following case, given by Dr. Trousseau, is an excellent instance in point:—

“Some of you may recollect a young mechanic, about twenty-five years old, who occupied bed No. 2 in St. Agnes ward. He had walked to the hospital, he was not lame, he used both his hands perfectly, his face was full of intelligence, and yet he was not able to answer any of my questions, although his tongue was very mobile. He heard me well and looked at me whilst I questioned him; his gestures, his looks, showed that he understood all I said; it seemed as if his mind were full of thoughts which he could not express in words. He knew how to read and write, and yet when I gave him a pencil and some paper and asked him to write his name down, he held the pencil properly, but only wrote meaningless letters, and then threw away the pencil in a fit of impatience. He, however, remembered a few words which he kept constantly repeating, showing at the same time by his manners that he well knew how little those words expressed his meaning. His illness had set in suddenly after certain excesses. . . . Before a fortnight had elapsed

the young man recovered completely, without having been subjected to any treatment, and was able to leave the hospital. . . ."

As to the question whether aphasia depends on a lesion of the posterior portion of the third left frontal convolution, as asserted by Mr. Broca, or on disease of some portion of the left hemisphere of the brain, as first suggested by Dr. Dax, we must refer our readers to Dr. Trousseau's work for the cases and arguments showing the untenability of either of those views. For our part we fully endorse the author's opinion that aphasia may coexist with *left* hemiplegia, although, in the great majority of instances, the paralysis, when present, affects the right side of the body.

Progressive locomotor ataxy is an affection to which prominent attention has only been given of late years. The late Dr. Todd had noticed that in certain cases of paraplegia the faculty of coordinating voluntary movements, was principally, if not alone, at fault, and that in such cases the posterior columns of the spinal cord were, after death, found to be disorganized. But Dr. Todd only said a portion of the truth, and by retaining this affection in the group of paraplegia, he clearly showed that the other phenomena, indicating progressive locomotor ataxy to be a distinct form of disease, had escaped his notice—namely, the implication of some of the cranial nerves, chiefly those of the eyeball, and the extension of the ataxy to the upper limbs. Dr. Duchenne (de Boulogne) undoubtedly deserves the credit of having been the first to give a complete and accurate clinical account of this malady. Romberg's description of *tabes dorsalis* evidently refers to the same affection, although it is inaccurate in some respects, and notwithstanding the grave error made by the great German neurologist with regard to the actual motor power of the patient. Be this as it may, Dr. Trousseau's Lecture on Progressive Locomotor Ataxy will be found to contain the best and fullest account of this affection, taken in conjunction with the Appendix added by the Editor, who has put on record a highly interesting series of cases of this disease which came under his observation at the National Hospital for the Paralyzed and Epileptic. These cases, which have been carefully observed by Dr. Bazire, and are fully reported, will well repay perusal. The most characteristic symptom of progressive locomotor ataxy is the peculiar gait of the patient, which, when seen once only, can never be mistaken. The description of it by Dr. Trousseau is so good and so truthful that we cannot resist the temptation of quoting it:—

"If you ask an individual suffering from ataxy to walk, he staggers, makes great efforts to maintain his equilibrium, and, feeling that his muscles do not respond to the influence of his will, he seeks for a point of support. It is especially at starting that this difficulty in maintaining the equilibrium of the body is remarkable. When once started, the patient is able to walk, although he does it badly, and throws his legs about to the right and to the left. Occasionally he loses his equilibrium entirely and falls down, unless he be supported, especially when he turns round. Formerly a man whose gait was uncertain, whose legs were thrown to the right and to the left, was set down as suffering from paralysis, and if no serious impairment of the intellect were present, the disease was localized in the cord, and called paraplegia. No physician before Dr. Duchenne (de Boulogne) ever thought of testing the muscular power of these so-called paralytic patients. The idea first occurred to this *savant*, and he it was who detected that their muscular power was considerable, and that they only lacked the faculty of coordinating their movements. . . . Whereas in true paralysis the leg is slowly lifted off the ground, and is dragged along; in ataxy the foot is thrust forward in variable directions, and comes down suddenly. Instead of the measured flexion of the knee-joint, which obtains normally, the flexion is sudden and followed by forcible extension."

Glossolaryngeal paralysis is an affection about which very little is known, and for the little we know we are in-

debted to Dr. Duchenne and Dr. Trousseau. It is still a question *sub judice*, however, whether it should be regarded as a distinct affection or merely as a variety of that obscure disease, progressive muscular atrophy, so often improperly called wasting palsy. A case detailed by Dr. Bazire, in which glossolaryngeal paralysis coexisted with marked atrophy of the muscles of the limbs, and even of some of the muscles of the trunk, would lead one to believe that paralysis of the lips, tongue, and soft palate, is only a complication, although a rare one, of progressive muscular atrophy.

Dr. Trousseau's views with regard to epilepsy, and the service which he has rendered to practical medicine by calling attention to nocturnal epilepsy, and to that peculiar modification of the disease which has been inaptly called vertigo and is better termed *petit-mal*, in contradistinction to the violent convulsive seizures or *grand-mal*—the epileptic fits proper—are too well known to require more than being adverted to. The remarks on treatment are sensible and practical, the importance of the mode of administering belladonna, which the author regards as the sheet-anchor in the treatment of this dire disease, is fully dwelt upon, and deserves the consideration of every practitioner. Of late years a new remedy, the bromide of potassium, has come into vogue in the treatment of epilepsy in this country, and from the statements made by the Editor in an Appendix on the physiological and therapeutic effects of this drug, and on the results which he has obtained at the Hospital for the Paralyzed and Epileptic, we may feel inclined to indulge the hope that this remedy will not, like so many others, be put by and laid on the shelf, and that we may at last have found a drug capable, if not of curing, at least of diminishing the frequency and severity of epileptiform seizures in general.

According to Dr. Bazire—

"The therapeutic effects of bromide of potassium are manifested within a short time. It has a decided and marked power of checking the fits, and short of averting them, of diminishing their severity and their duration. Under its influence they become less frequent and severe, the intervals between them more and more prolonged, so that patients who used to have a fit every day, and sometimes several fits in the day, are free from any seizure for a week, and for two, three, four weeks, and more. This influence is extremely marked in recent cases of epilepsy, and seems to diminish in proportion as the disease has extended over a long period of years. In the first class of cases, the intervals between the paroxysms go on increasing in length, whilst in the second, the only sure effect obtained by the administration of the medicine, is a diminution in the number and severity of the fits."

The first Lecture contained in this Part—namely, that on "Venesection in Cerebral Hæmorrhage and Apoplexy," is of the highest importance in a clinical point of view. There has been, of late years, a growing dislike to the use of the lancet in the treatment of disease, and whether or not disease has really undergone a "change of type," certain it is that we find it advantageous to bleed now-a-days infinitely less than our predecessors did. We feel sure, therefore, that Dr. Trousseau's rejection of bloodletting in any shape, in cases of apoplexy, will meet with the concurrence of many practitioners in this country.

We have only to state, in conclusion, that Dr. Bazire has most ably performed his part of the work as Editor and Translator. Himself a pupil of Professor Trousseau, and now carrying on in London the same species of investigations as those which have so long engaged the attention of his distinguished teacher, Dr. Bazire has enriched the book with a number of notes and appendices, which, while they in no way interfere with the text, often amplify and corroborate the views advanced in the Lectures, and prove in no ordinary degree his own talent for original observation and research.

PREVENTIVE MEDICINE.

IT would be dishonest, even on the part of the Medical Profession itself, to over-rate or exaggerate the powers of Medicine, to pretend that it holds the balance between life and death for the human race, or that it has found a remedy for all diseases. While this allowance must in fairness and truth be made in the case of certain accidents and maladies of pretty frequent occurrence, it must also be made, although in a somewhat modified degree, in relation to most epidemics, and in a less degree still, to the whole tribe of what are now generally known as zymotic affections. It is the province of quackery to pretend that human skill has discovered a remedy for the dissipation of a cancerous tumour, has invented a medicine for the solution of a cataract, has devised drugs which can cut short the paroxysm of a fever, or has hit upon a panacea which shall arrest an epidemic of cholera. Legitimate Medicine is not ashamed to confess that her weapons are powerless in certain cases, and that all she can hope to do in many instances is to allay present suffering, and perchance to smooth the passage to the grave; while quackery, on the other hand, holds out hope where there is no hope, and what is worse, extorts from the credulous patient large sums of money which the honest practitioner would refuse to accept.

In reference to the class of epidemic and epizootic maladies, to which our present remarks are intended particularly to apply, the difficulties encountered by legitimate Medicine are avowedly very great. It is true that there is nothing impossible in the idea that a cure may hereafter be found for an attack of Asiatic cholera, just as an antidote may one day be discovered for a large dose of prussic acid. Death in both cases is caused by the presence of a poison in the human body, and if this poison can be eliminated or neutralized, health may be restored; but in the present state of our knowledge it must be confessed that, in either case, the medicinal substance has not yet been discovered which can overcome the subtlety and the rapidity of the morbid agent. In a less degree than in the case of cholera or of poisoning by prussic acid, the march of some of our more common indigenous maladies, such as typhus and small-pox, sometimes defies the powers of Medicine, and casts a kind of opprobrium, however undeserved, upon the professors of the healing art.

The observations we have made are, we conceive, particularly appropriate at the present time, when, both abroad and at home, we have been visited, and are still visited, by some of the most fatal scourges, in the form

of epidemics, that the world has ever known. On the great continent of India, cholera, instead of being, as with ourselves, an occasional intruder, is a constant, though most unwelcome, guest, and the same epidemic, spreading from the plains watered by the Ganges and the Indus, has extended by rapid marches to the shores of Europe, and has not only threatened, but actually attacked, our own land. Whether our recent experience of this malady has shown that it has touched us only slightly, or whether its transient ravages are really the forerunners of a more dreadful visitation in the ensuing spring and summer, are problems only to be solved by the progress of time, and their contemplation should teach us neither to allow ourselves to be lulled into a false security, nor to abandon ourselves to needless despair.

In the meantime, however, we have among us the plague among the cattle and typhus among ourselves. In the case of the former, no remedy has yet been devised on which any reliance can be placed, and as for the latter, Medical Science has often been baffled in its treatment. It is no part of our duty, any more than it is our inclination, to pretend that we possess a cure for the rinderpest, or that by the administration of drugs we can stop an attack of typhus, or protect communities from its infection. But what we do know is, that by measures of prevention we can preserve the healthy from contamination from the sick, and that it is mere waste of time to delay such measures while we are discussing the merits of some useless though much-boasted nostrum. Even in the case of cholera in India, where the disease, as is well known, is seen on a very extensive scale, the fatal results may, in a great measure, be averted by timely precautions, and just as the rapidly falling barometer at sea warns the mariner to steer his vessel beyond the circumference of the cyclone, so the occurrence of a few cases of cholera in the Asiatic plains may warn the general to remove his troops as fast as possible from the centre of infection to a more salubrious locality, and thus to save hundreds or thousands of lives.

Typhus, although it may be allied to cholera, is certainly not produced by the same identical causes, and is not amenable to exactly the same laws. We have never heard of typhus fever attacking an army on the march in the open plain; nor have we ever heard of cholera being perennially located in Bethnal Green or in the St. Pancras Workhouse. There is much reason to believe that while cholera is generated by certain undefined and mysterious conditions of the atmosphere, and travels over large tracts of countries, seas, or rivers, typhus, on the other hand, is produced, or it might even be said, manufactured, by well-known endemic causes, as overcrowding, bad ventilation, poverty, and dirt. Experience has certainly shown that the last-named conditions are the fertile sources of typhus, and that when they are removed, typhus ceases to exist. Cases in illustration have of late been so common, or rather

they have lately been so prominently brought before the public through the medium of coroners' inquests and the industry of the press, that it is almost unnecessary to dilate upon the relations between cause and effect, which these revelations are daily developing. As Medical writers, we have known all these truths long ago, and our brethren have repeatedly represented them to the local authorities, but hitherto without avail. Now, however, the eyes of the general public are opened, and the fearful consequences of local mismanagement and local jobbery are made manifest. Now, it is shown that parochial Vestries have been guilty not only of ignorance and apathy, but that some members of those bodies have resisted sanitary improvements on mere selfish and sordid grounds, and because their own interests were concerned in the retention of existing nuisances. Now, it has been shown that the Medical Officers of Health, appointed expressly for the purpose of guarding over the public health, have been compelled to ignore the existence of death-producing causes, because their representations might have compromised their salaries. Now, it is likely that Legislative interference will compel the Vestries and the so-called Guardians to fulfil the trust which they have shamefully and almost criminally betrayed, or to resign their power into other and more competent hands. The ignorance and the vanity of the local Boards have at last been exposed, and there is now a glimmering of hope that sanitary science and the principles of preventive Medicine will have a chance of being understood, at least by those who exercise the supreme control over public affairs, but who have hitherto, from a false feeling of non-interference, allowed the principle of local government to run into unwarrantable excess. It is this principle, which, though good in itself, has enabled a few demagogues and upstarts in the city parishes to turn a deaf ear to the teachings of science and even to the voice of humanity, to sacrifice the health and comfort of the poor, to insult the Medical Profession, and finally, to bring disgrace upon the system of which they themselves are the administrators.

NOTES ON THE CURRENT TOPICS OF THE WEEK.

THE HUNTERIAN LECTURES AT THE COLLEGE OF SURGEONS OF ENGLAND.

PROFESSOR HUXLEY is now delivering the annual course of Lectures on Comparative Anatomy in the theatre of the College, his present subject being the structure of the Cetacea, a class of animals in which John Hunter took a very great interest, and many specimens of which are contained in the College Museum. These curious, and, in some respects, paradoxical animals, the mammalia of the sea, are divided into two groups by modern zoologists, one termed the Sirenia, and comprehending only two genera, the halibore, or dugong, and the manatus, and the other group comprising the true cetacea, as the whales, dolphins, and porpoises. The largest of these creatures, as is well known, is the whale or *balæna*, and this again is

divided into two species or rather genera—namely, the Northern and the Southern whale, called respectively the *Balæna mysticetus* and the *Kalæna* (or *Eubalæna*) *Australis*. Of the former the Museum of the College now possesses a magnificent and complete specimen, which has only very lately been fitted up in the large hall of the Museum, where it forms the most conspicuous and imposing feature of the collection. As this is the only complete specimen of the Northern whale yet exhibited in this country, all lovers of Natural History and of Comparative Anatomy should not fail to visit it. Besides its enormous bulk, it illustrates many interesting points in morphological anatomy, which are carefully displayed by Mr. Flower, the Conservator of the Museum, under whose able superintendence the huge monster of the deep has been placed in close quarters. Among these points we may notice the hyoid bone, forming with the detached styloid processes, and the petrous portion of the temporal bone, a ring of bony and fibrous tissue, for the passage of the trachea and œsophagus; and the curious rudimentary pelvic bones, with their dwarfed femoral bones, representing the pelvis and lower extremities of the terrestrial mammalia. The *Balæna mysticetus* is the whalebone of the North Seas, and the head is exceedingly large, the great space between the upper and lower jaws being enclosed by the layers of whalebone, the interstices of which entangle the small soft and semi-gelatinous animals abounding in myriads in the Northern and Southern Ocean, and forming the natural food of the whales.

THE LEGISLATURE AND THE CATTLE PLAGUE.

THE change of opinion that has occurred in the public mind on the subject of the cattle plague has been most remarkably exemplified by the proceedings in the Houses of Parliament since they began their sittings, and more especially by the alacrity with which the House of Commons has been pushing on the Bill proposed by Sir George Grey. It is only due to the Cattle Plague Commissioners to state that in October last they recommended, but in vain, the very steps which are now being taken to prevent the spread of the disease. At that time, public opinion, followed and encouraged by the Solons of the *Times*, ridiculed the fears expressed by scientific men, denounced their recommendations as impracticable, and encouraged the quacks to waste precious time in the trial of their pretended panaceas. The consequences have been even more disastrous than were contemplated, and the disease has extended so rapidly that universal alarm has at length compelled the public to take measures of safety, and has aroused even a slothful Government into activity, if not energy. So great is now the excitement throughout the country, and in consequence, among the members of both Houses of Parliament, that their zeal for repressive measures outruns that of the Ministry, and the latter were actually beaten on Thursday night on an amendment which proposed that all traffic of cattle should be absolutely stopped. The Government, in their Bill, had rendered this step permissive only, but the amendment made it obligatory, and as we have stated, the Ministry was defeated. So rapidly is the Bill, with its stringent amendment, passing through committee, that it is not improbable it may be the law of the land before the present number of this journal is in the hands of our readers. The chief features of the measure will, no doubt, be the slaughter

of the infected cattle, the isolation of those in contact with the disease, the absolute stoppage of transit of the beasts, the establishment of dead meat markets, and the slaughter of foreign cattle at the port of debarkation. There will necessarily be some inconvenience to the buyers and sellers, and perhaps to the consumers of meat, but the steps to be taken are imperatively required, unless greater evils are to be brought upon us by our apathy and negligence.

NATURAL SCIENCE AT CAMBRIDGE.

SOME important changes are in progress at Cambridge in reference to the cultivation and encouragement of Natural Science in the University. Dr. Clarke, who has for a long time held the appointment of Professor of Anatomy, has sent in his resignation, and it is expected that Dr. Humphry, who has for some time most ably performed the duties of the Professorship, will be elected to the vacancy. A Demonstrator of Anatomy is also to be appointed at a salary of £100 per annum, and a new professorship is to be formed of Comparative Anatomy and Zoology, at a salary of £300 per annum. We understand that the competition for the last named post is open, the candidates not being required even to be members of the University.

THE SPHYGMOGRAPH.

DR. B. W. FOSTER communicated last week to the Midland Medical Society a paper on the investigation of the pulse in disease by the sphygmograph, which, as far as we know is the first systematic treatise on the subject, which has been laid before any English Society. We hope to give the paper in abstract in a coming number. The paper was illustrated by a large number of pulse tracings which the author had taken from various cases of heart disease and other affections. Dr. Foster pointed out the manner in which the use of the instrument afforded not only valuable aid in diagnosis, but also in prognosis.

DEFICIENT BRAIN SUBSTANCES IN THE MORALLY INSANE.

WE understand that the brain of Mr. Windham, the notorious amateur footman and coachey, has been subjected to examination since his death, and that the result goes to prove that the depravity of mind which he displayed during life was at least coincident with smallness of brain. He died of embolism of the pulmonary artery. We need not mourn for his loss, for his vices were even more ruinous to public morality, as an example to young men, than they were to himself, his fortunes, and his family.

THE PROFESSORSHIPS OF HUMAN AND COMPARATIVE ANATOMY AT CAMBRIDGE.

A CONGREGATION was held on Thursday last, when motions were submitted having for their object the adoption of the report of the syndicate appointed to consider of the best mode of providing for the teaching of anatomy and zoology in the University. The first proposed that the Professor of Human Anatomy and Physiology be appointed, separate from the other departments, and that the sum of £300 per annum be continued to him on certain conditions, this was carried by 152 placets to 15 non-placets. The second proposing the appointment of a Demonstrator in Anatomy, at a stipend of £100 per annum was unopposed.

The third proposing the appointment of a Professor of Zoology and Comparative Anatomy, who should arrange with the Professor of Anatomy, the lectures so as to be mutually dependent, and serve the medical as well as the natural science students, the salary to be £300 per annum, was carried by 163 placets to 17 non-placets.

QUACK ADVERTISEMENTS.

THE Editor of the *Sporting Times* takes the credit which is justly due for refusing the income which his contemporaries derive from quack advertisements. It is hardly in the power of the medical profession, by its patronage of the *Sporting Times*, to recoup the loss; but we have no doubt that the public are not without appreciation of such a sacrifice of personal interest. We are aware that a large number of medical men have transferred their orders from the *Daily Telegraph* to the *Standard* and *Morning Herald*, feeling themselves, though in many instances, not concurring in politics with these latter journals, bound to support the right of conscience against the might of pocket.

PROVINCIAL INTELLIGENCE.

BIRMINGHAM.

FROM OUR OWN CORRESPONDENT.

FEBRUARY, 1866.

IN Birmingham, as many of the readers of THE MEDICAL PRESS AND CIRCULAR are doubtless aware, there are two Medical Schools—the Queen's College and the Sydenham College. The first mentioned of these institutions has been developed out of the Royal School of Medicine and Surgery, and was incorporated by Royal Charter in 1843. For some years it enjoyed great success, but for the past ten years or so it has by no means advanced. Scarcely a year has passed over without some resignation in the staff; many have seen an almost wholesale retirement of the Medical Professors, and on each occasion the public press of the town has been favoured with the full details of these squabbles. In this way the College has pursued its declining path, ever mindful "to wash all its dirty linen outside its own doors," till at last its continued existence as a Medical School has become a mystery to some, and to others the strongest proof of its inherent vitality. Under the guidance of its present Principal, the Earl of Lichfield, the College has reached that haven, the Court of Chancery, to which all such institutions drift sooner or later in the endeavour to find some mode of reformation; and only a few days back the Solicitor of Her Majesty's Attorney-General held a Court at the College for the purpose of receiving suggestions as to the scheme to be proposed for the future regulation of the institution. The meeting was not a large one, for the public of Birmingham have become very weary of hearing of the College and its affairs. The College debts were stated to be about £10,500, and several schemes were suggested whereby the sum might be raised. Some few unimportant proposals were also offered for the future management of the Medical School; but, strange to say, no mention whatever was made in favour of the only scheme on which the restitution of the College can ever be thoroughly realized—viz., the amalgamation of the Sydenham and Queen's Colleges. Some few months back, before the case of the Queen's College had been certified to the Attorney-General, an attempt was made to bring about this most desirable of all reforms, but without success. This fusion

of the Medical Schools would, however, if accomplished, yield such great results, that one wonders that a single failure under very exceptional circumstances should be accepted as decisive. Birmingham, with its two large General Hospitals and its special institutions in addition, its almost unrivalled material for the surgeon, and its central position in the midst of perhaps the most populous district in England, might have by the united energy of its medical men the best School of Surgery in the Kingdom, and the most flourishing Medical School in the Provinces. The existence of two Medical Colleges is fatal to the great success of either, and it is to be hoped that the scheme of the Attorney-General will include some arrangement whereby the Physicians and Surgeons of the General and Queen's Hospitals may be united in the work of a single Medical School. Any plan that can secure the coöperation of the staff (or even a majority of them) of both Hospitals in one College, must necessarily lead to the construction of *one* flourishing School from the materials that now support *two* of moderate size.

At the Midland Medical Society two interesting meetings have been held this year, and some remarkable pathological specimens have been exhibited before the reading of the papers. By a law of the Society it is arranged that the first three-quarters of an hour of each meeting be devoted to the presentation of pathological specimens; by this means the meetings have been rendered much more popular and instructive. At the first meeting of the year Dr. Casey of the General Hospital brought before the Society a remarkable specimen of acute necrosis of the tibia and femur. This affection has recently been described by Dr. Roser (*Archiv der Heilkunde*) under the name of "Pseudo-Rheumatic Ostitis." The case from which the bones were exhibited had been admitted into the General Hospital, suffering apparently from acute rheumatism. Symptoms of severe periostitis and supuration about the joints supervened, and after death the tibia and femur on the affected side were found in a state of acute necrosis. The specimens excited much interest. At the same meeting Dr. Wade read a paper on "A Peculiar Form of Alcoholism" observed by the author in young women. The patients were usually found in a state of complete insensibility; no smell of alcohol on the breath, no stertor was observed, and no symptom of hysteria was detected. Dr. Wade had doubt about the cause of these appearances for some time till he had the opportunity of tracing the symptoms to the effect of alcohol. The paper was ably prepared, and excited much discussion among the members.

At the last meeting of the Society, Dr. Foster read a paper on "The Investigation of the Pulse in Disease by the Sphygmograph." The paper was illustrated by numerous pulse-tracings collected by the author.

Much remark has been excited here by a review which appeared in a late number of the *Lancet* on a book by Dr. Earle of this town, "On Flooding after Delivery." The *Medical Times and Gazette*, the *British Medical Journal*, and the *Medical Circular* had previously each contributed their share of approbation to the work, when it attracted the notice of the *Lancet* reviewer, and at the same time his severe criticism. It is not the place here to enter into the merits or demerits of the book in question. We can only mention the treatment Dr. Earle has received as indicating a very bad state of medical criticism. Three papers of acknowledged standing notice the work favour-

ably, and then an unfavourable notice appears in the leading medical journal. There are many obstacles to the improvement of the present state of medical criticism, but we think they are not insurmountable ones. Its chief fault is less often its severity than its laxity, and until a more searching style of criticism is adopted reviews cannot be esteemed for much. In THE MEDICAL PRESS AND CIRCULAR justice will, we trust, always guide the pen, severity will appear when needful, partiality never.

MESSRS. MAW'S CATALOGUE.

MESSRS. MAW and SON have just issued a new edition of their Catalogue of Surgical Instruments, Air and Water Beds, Pillows and Cushions, Bandages, Trusses, Elastic Stockings, Inhalers, Galvanic Apparatus, and other appliances used by the profession. The work is very handsomely got up, and abundantly illustrated with engravings of the various appliances described, and, independently of its utility as a guide to the Messrs. Maw's repertory, it may be said to form a complete epitome of the armamentarium of the physician and surgeon, the instruments themselves not only being figured, but, in some instances, the mode of using them being also delineated. We understand that Messrs. Maw's instruments may be obtained from most respectable chemists throughout the United Kingdom on the same terms as if purchased direct from the London establishment.

MEMORANDA OF THE MONTH.

AN able letter from Dr. W. D. Moore of Dublin appears, rescuing his personal friend, the great physiologist, Van der Kolk, from a series of heterodox views ascribed to him recently in a leading London *Review*, the fact being, as stated now by Dr. Moore, that in place of such materialistic ideas, the great Dutch anatomist opposed these views, and in place of the assumption of our *Fortnightly Review* of a voluntary will or mind, even in the spinal cord, Van der Kolk looked on it as an absurdity, "the nervous system being arranged as a perfect minister of the soul and will."

Considerable discussion has taken place and continues in the *Times* as to the first demonstrations in London of the nature of trichina in pork. A preparation in Guy's of 1828 seems to be the earliest*, while the *Athenæum*, in the well-known and admirable book notices ascribed to Dr. Lankester, gives nearly all the credit of what has been since written by Virchow, Althaus, Kuchenmeister, &c., to an entirely different writer of the German school.

The French claim for Pinel the merit of establishing the non-restraint system in lunacy, and to Flourens is due the first use of chloroform, copied subsequently in Edinburgh. So it is of interest to know, *en revanche*, that all the glory of trichiniasis is not French or German.

An interesting practical fact, enunciated in the late Hastings Prize Essay, seems to be of more or less importance in these days of "Health of Towns" dissertation—viz., that sulphate of zinc and sawdust is the best combination as a deodorizer, especially where it is necessary to make post-mortems or preserve bodies in private houses. Tar and chlorine are not pleasant, as they have well-known and not agreeable odours of their own. We

* Dr. Jacob, the Professor of Anatomy and Physiology at the Royal College of Surgeons in Ireland in the year 1814, observed and called the attention of Professor Colles to a subject in the dissecting-room, the muscles of which were affected with trichinous disease.—ED. M. P. & C.

have seen charcoal also used in St. Bartholomew's and other dead-houses in London with considerable success.

To those curious in hospital statistics perhaps mention may be made here of some of the resources, startling, if not luxurious, of our London hospitals. St. Bartholomew's hospital has 600 beds; each bed is occupied ten times a year by a new patient, equivalent, of course, to 6000 patients a year. It has 30 "Sisters" or head nurses, divers of whom would "put up" a fracture or pick out the appropriate splint better than any of the students, besides 100 ordinary nurses, and its income from capitalized receipts of sale of lands given by Parliament is £32,000 a year! Fifteen pipes of port wine alone a year is given to the patients, with innumerable other cordials and vinous tonics. Epsom salts are, we suppose, bought by the ton, castor oil in hogsheds. £600 worth of quinine has been purchased at one order. There are four apothecaries, and a steam engine grinds the drugs.

In some excellent clinical remarks one day this month by Sir W. Fergusson, on two cases of inflammation of bone and necrosis, a somewhat bold practice was advocated, that of early search for the dead bone, whether loose or not, as, when the bone is loose, the sequestrum is easily removed, giving much ease to the patient; and when the bone is not yet loose a tissue, soft like lead, is cut through, and leaves the subsequent issue of the dead bone easier often preventing amputation being had recourse to, though there are conceivable uncertainties as to the time that dead bone in reality separates.

We have had a remarkable case of Cæsarean section at St. Bartholomew's Hospital. The child was saved, but the shock to the poor mother was too great for her to survive. The Chemical Society has had an able lecture and debate on the often vexed question of town sewage, the general conclusion being that the liquid sewage is only applicable to irrigation of grass crop, when the yield of grass is increased three or fourfold. This does not square with the view of our learned contributor, that we should have no sewage or sewers. Of other points of less or more physiological interest it may be noted that the Pathological Society has been improving the occasion of the debates on Jamaica to send at their own expense a special ethnological commissioner, Mr. Pritchard, to that island to report on the peculiarities as to races, which have been the ultimate causes of the late negro outbreak. The long expected and capital work of Gamgee on "The Cattle Plague," published by Hardwicke, has this week seen the light. This and the book of Marion Sims, and one half-printed by Baker Brown on "Epilepsy," prove to be the most interesting of the season. A new work, by Professor Roen, on "Fishes and Reptiles" also engages attention as on the great question of Darwinism or development, the ex-curator of Lincoln's-Inn Fields still seems to take rather with Lanark than the red-hot Huxley school.

DR. PATERSON AND THE PRITCHARD CASE.

FROM AN AUSTRALIAN POINT OF VIEW.

HAVING just received the *Australasian Medical and Surgical Review* for November 1st, 1865, we make the following quotation from it for the purpose of showing that, although doctors are proverbially said to differ, we are at one all over the world in repudiating the idea over which DR. PATERSON so complacently glories, that he, DR. PATERSON, had done all in the power of an honourable man to do,

under the peculiar circumstances of the case, and had successfully shifted the burden of disgraceful concurrence in the PRITCHARD crime from his own to the Registrar's shoulders:—

"Whether Dr. Paterson would have saved Mrs. Pritchard's life, had he told Pritchard that he suspected she was being slowly poisoned, it is difficult to say. If he had secured some of her urine and feces when he visited her during Pritchard's absence at Edinburgh, he would have furnished himself with sufficient proof of the existence of the drug to have enabled him to put a stop to what he knew was going on, especially as he had seen another person die in the house under suspicious circumstances. It must, no doubt, be a subject of deep regret to him now that he allowed his chivalrous feeling to over-ride his judgment, and allow a second murder to be committed."

When the writer comes to read the self-glorifying speech delivered in Glasgow on the 21st of December ult., he will perceive with sorrow that Dr. PATERSON is still too full of self-conceit to permit as yet the entrance of any of those feelings of deep regret at his ill-advised conduct, feelings which must sooner or later make themselves felt, or he must be something—at least different—from ordinary men.

PROFESSOR W. T. BRANDE, D.C.L., F.R.S.L. & E.

WE have to record the death of this well-known chemist, who, although never in actual practice, was a member of the Medical Profession. He was born in 1786, and was grandson of a physician who came from Hanover with George III., and was that king's physician. After an education at Westminster he was sent to Hanover, but in 1803, on the panic of Bonaparte's invasion, he returned home and entered at St. George's Hospital, attending the lectures and the dissecting-room, and communicating several papers to *Nicholson's Journal*, notably one on guaiacum, which was read before the Royal Society. In 1808 he examined the calculi at the Hunterian Museum, and lectured on chemistry at Dr. Hooper's, in Cork-street. Then he became connected with the new medical school in Windmill-street, and fairly embarked as a teacher and demonstrator of chemistry. In 1809 he became F.R.S., received the Copley Medal in 1813, and from 1813 to 1826 was Dr. Wollaston's successor as senior secretary to the society. In 1812 he became Professor of Chemistry and *Materia Medica* to the Apothecaries' Company, and in 1851 was elected Master. In 1813, on Sir H. Davy's recommendation, he was appointed Professor of Chemistry at the Royal Institution, and delivered lectures for many years in conjunction with Mr. Faraday, who was also associated with him as editor of the *Quarterly Journal of Science* for many years. In 1825 he was appointed superintendent of the die department of the Mint; in 1836 Fellow, and in 1846 Examiner on Chemistry at the London University. Besides Professor Brande's famous "Manual of Chemistry," which has been translated into many foreign languages, he was author of "Outlines of Geology," "Dictionary of Science and Art," &c. In 1853 he received the honorary degree of D.C.L. from Oxford University.

Although Mr. Brande had attained a somewhat patriarchal age, he was until very lately in the enjoyment of excellent health, and died of an attack of chronic bronchitis, after only a few days' illness. His death has severed another link between the present and the past, as he was fellow-lecturer with Sir Humphry Davy at the commencement of the present century, and at the time of his death was preparing another edition of his work on "Modern Chemistry." Mr. Brande will long be remembered by a large circle of pupils and friends as one of the best lecturers on chemistry of recent times, his delivery being clear, fluent, and graceful, and his experiments uniformly successful. He was an excellent speaker and a ripe scholar, and his manners were kind and urbane. Although not possessing the originality of genius of his colleague, Mr. Faraday, he was a man of sound and extensive scientific attainments, and the reputation of the Royal Institution as one of the most distinguished schools of chemistry in this country lost nothing while he held the position of one of its Professors.

ARMY MEDICAL SCHOOL, ROYAL VICTORIA
HOSPITAL, NETLEY.

Examination at the close of the Eleventh Session, between
January 31, 1866, and February 6, 1866.

A. *Written questions; three hours for each paper.*

Wednesday, January 31, 1866.

I. MILITARY HYGIENE.—PROF. E. A. PARKES, M.D., F.R.S.

1. Give an account of the present system of ventilating barracks on home service. State what amount of air must be supplied to maintain proper purity of air, and how you would ascertain that the air of a room is pure, and is being supplied in proper quantity.

2. What is the evidence that cholera may be produced by impure water? How would you detect organic impurity in water, and how would you remove it?

3. Give a brief account of the amount of sickness and mortality on home service and in the West Indies, and state what preventive measures you would adopt against typhoid fever at home and yellow fever in Jamaica.

Thursday, February 1, 1866.

II. MILITARY MEDICINE.—PROF. W. C. MACLEAN, M.D.,
DEPUTY INSPECTOR-GENERAL.

1. Give a general description

a. Of the symptoms of yellow fever.

b. The geographical limits within which it can be propagated; the temperature necessary for that propagation; the elevation above the level of the sea to which it is usually restricted, and any remarkable exception to the rule of elevation with which you are acquainted; state

c. Whether it is a form of malarial remittent, or whether it is specifically distinct.

d. What are the conditions which most favour its propagation?

e. What advice would you give to the officer in command of troops in a town or garrison attacked or threatened by the disease? describe

f. The arrangements you would make for treating the sick, should the disease establish itself among the troops.

2. Give a definition of cirrhosis of the liver; its cause, its consequences, and its final results, with an account of the management of a case,

a, in the early,

b, in the later stages of the disease.

3. What are the causes that appear to excite heart diseases in the army? What are the signs of mitral disease? Describe the phenomena in their natural sequence which lead in this disease to a fatal termination, and the best mode of mitigating their effects as they arise.

Friday, February 2, 1866.

III.—MILITARY SURGERY.—PROF. T. LONGMORE, DEPUTY
INSPECTOR-GENERAL.

1. What are the characteristic features of wounds inflicted by bayonets? Name the chief points to be attended to in the treatment of a stab by one of these weapons.

2. Describe the various kinds of wounds of the bladder which result from musket balls, the complications which occasionally accompany them, and their treatment.

3. What are the optical effects produced by removing the crystalline lens, as in an operation for cataract, according as the eye operated upon has been previously emmetropic, myopic, or hypermetropic?

B. PRACTICAL EXAMINATION.

Monday and Tuesday, 5th and 6th February, 1866.

I. MILITARY MEDICINE.

Make an examination of the case of ———.

You are required to write, concisely, a history of the case, your diagnosis, prognosis, the probable effects of the treatment, and the influence of the disease on the man's fitness for service as a soldier.

Written notes may be taken.

Twenty minutes allowed for the examination, thirty for the description.

II. MILITARY SURGERY (no Clinical Cases available.)

Write a description of any one of the preparations which

you choose to select out of the four placed upon the table, and indicated by the letters A, B, C, and D. Describe the surgical injury which the preparation illustrates, and state any facts with which you are acquainted in reference to it, bearing upon diagnosis, the pathology of repair, or treatment.

Twenty minutes allowed for observing the preparation, and one hour for writing your remarks upon it.

III. MILITARY HYGIENE. (Three hours allowed.)

1. Chemical examination of various specimens of water.

2. Examination, for acidity, of a sample of vinegar.

3. Microscopic examination of a sample of adulterated mustard.

IV. PATHOLOGY. (Three hours allowed.)

1. a. Name each of the parasites in the jars marked respectively A, B, C, D, and E;

b. State what parts of the bodies of men or animals they each inhabit;

c. Mention the probable source whence each may enter the body of man.

2. Examine microscopically, by section or otherwise, the portion of tissue in the gallipot before you.

State of what organ it is a part, and describe its morbid condition.

3. What are the lesions shown in the preparations numbered respectively 1, 2, and 3? Mention the diseases of which they are the results, and the probable stage of the disease to which they correspond.

4. Determine the magnifying power of any one of the four microscopes marked 1, 2, 3, and 4; appending the magnified image of the scale used.

Saturday, February 3, 1866.

IV. PATHOLOGY.—PROF. W. AITKEN, M.D.

1. Describe the lesions which are peculiar to typhoid or enteric fever and characteristic of that disease. Describe them as regards—

a, Their anatomy;

b, Their progress and development in relation to the progress and duration of the fever;

c, The modes in which the lesions heal or prove fatal.

2. Mention the normal temperature of the human body at completely sheltered parts of the surface (say axilla), and give a concise account of the pathological significance of records of temperature, taken daily, in cases of acute diseases, and the precautions to be observed in taking the observations.

3. Describe the prominent lesions seen at the post-mortem examination of Private James O'Connor, who died January 14, 1866, and whose body was examined on January 18th. He had completed one year and four months service, and was 25 years of age. His service had been at home and at Malta. When at Malta, in August, 1865, he was attacked with continued fever, which was followed by rheumatic fever, cardiac pains, and endocarditis. A permanent aortic bruit followed on this last illness. On admission here in December last he was emaciated, his face was puffed, and his ankles were œdematous. He had frequent attacks of dyspœna, with harassing cough. The cardiac bruit was loud and systolic, and heard loudest at the base and along the course of the large vessels. Describe

a. The lesions seen in the heart and pericardium;

b. The condition of Peyer's glands;

c. The condition of the spleen;

d. The condition of the kidney.

Give a pathological summary of the case, and state the probable immediate cause of death.

Correspondence.

THE FELLOWSHIP OF THE COLLEGE OF SURGEONS OF IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with considerable interest your able article in this week's issue regarding the Fellowship of the College of Surgeons, and I have no doubt it expresses the feelings of the great majority of the Licentiates on the subject. When we consider the small number of gentlemen, and their status in the profession, who have obtained the Fellowship since 1844, it is evident that a reform in the bye-laws is needed

should the College wish to extend its corporate privileges. If carried, I cannot see what benefit will accrue to the College by Mr. Macnamara's motion—a few pounds more may be annually obtained, principally from Army and Navy Surgeons. If the College funds be in a dwindling state, why not throw open the portals as in 1844, and admit to the Fellowship any Licentiate willing to pay, say forty guineas. As to the clause forbidding Fellows "selling drugs and thereby making a trade of their profession," I would abolish it altogether. Indeed, it is absurd for a College of Surgeons or Physicians to insist on solemn declarations, &c., when no such exactions are demanded by the Universities from their graduates. If the Irish College of Surgeons wish to recoup its finances and maintain its influence in the Provinces it must popularize the Fellowship and give country practitioners a voice in its government. Then *acquire vires eundo*, for at present I am afraid it remains *in statu quo*. Thanking you for opening up the Fellowship question, I remain, yours very truly,

CHARLES GARLAND, L.K.Q.C.P.I., L.R.C.S.I.

We cannot concur with our correspondent in advising the Council of the College to abolish the restriction on the selling of drugs or the establishment of another year of grace. A line must be drawn somewhere, and we think the admission of persons not qualified to compete for the honour at other times by the expedient of a year of grace is alike unjust to those who have gone before and who come after.

POOR-LAW MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall feel obliged by your giving insertion to the following letter from the Poor-law Board. I strongly advise the Poor-law Medical Officers to forward their subscriptions, as it is quite possible we may yet have to fight the battle in the House of Commons, and therefore shall have need of funds. I am preparing a pamphlet explanatory of the various Clauses in the Bill, otherwise the Members of the House of Commons may be deceived, as the Select Committee were on a recent occasion.—I am, &c.,

RICHARD GRIFFIN.

12, Royal Terrace, Weymouth, Feb. 10, 1866.

Mr. Prowse of Amersham, has received the following:—Barker, Mr. Aldershot, 10s.; Bywater, F. E. G., Pontefract, 10s. 6d.; Meymott, H., Ludlow, 5s.; Pink, G., Petersfield, 5s.; Knaggs, S., Huddersfield, 5s.; Davies, F., Pershore, £1 1s.; Reddrop, J., Tiverton, 5s.; Norris, H. E., Bridport, &c., 5s.; Weston, R. P., Wellington, 10s.; Thomas, J. L., Carnarthen, 5s.; Holton, C., Stoke-on-Trent, 5s.; Pearson, J., Cokermonth, 5s.; Morgan, W. W., Newport, 10s. 6d.; Jennings, O. C., Newport, 5s.; Harday, G., Rugby, 10s.; Raymond, L. R., Bromsgrove, 5s.; Rhodes, G. W., Huddersfield, 10s. 6d.; McLachlan, R., Halifax, 10s.; Savory, J. T., Weycombe, 5s.; Spurgeon, C., Sainford, 5s.; Few, W., St. Ives, 5s.; Muriel, J. S., Cosford, 5s.; Leech, H. P., Stow, 5s.; King, E. P., Chepstow, 5s.; Dean, P. T., Upper Norwood, 5s.; Kingdon, A., Bideford, 5s.; Kendall, J. M., King's Lynn, 5s.; Newington, J. W., Cranbrook, 10s. 6d.; Royle, O. N., Kendall, 10s. 6d.; Elliott, J. R., South Molton, 10s.; Whitehead, W., Mansfield, 10s. 6d.; Lipscombe, R. M., Berkhamstead, 5s.; Pilkington, W., Blackburn, £1 1s.; Marley, H., Columb St. Major, 6s.; Hall, C. S., Carlisle, 5s.; Pritchard, W., East Retford, 10s. 6d.; Organ, R., Barwick, 5s.; Davison, R. S., Castleward, £1 1s.; Braach, J., Bradford, 10s.; Raynes, H., East Retford, 10s.; Cook, M., Barnstaple, 10s.; Hemsted, H., Whitechurch, 10s.; Jeffery, B., Worcester, 10s.; Day, R. W., Epping, 5s.; Robertson, W., Alnwick, 2s. 6d.; Foster, W. F., Isle of Wight, 10s.; Moore, A. J., Healey, 5s.; Cooper, W., Bristol, 5s.; Frankland T., Ripon, £1; Fitch, F., Kidderminster, 5s.; Jeston, A. F. W., Malmesbury, 10s.; Salter, G., Malmesbury, 10s.; Wheeler, G., Chelmsford, £1 1s.; Francis, W., Ycovil,

10s. 6d.; Herbert, W. A., Hemel Hempstead, 10s.; Fothergill, J., West Ward, 2s.; Cooke, R. E., Southwell, 10s.; Taylor, T., Cricklade, and Woolon Bassett, 10s.; La Fargue, P. A., Meriden, 5s.; Hancock, G., Hemslet, 5s.; Hodges, H., Hertford, 5s.; Pridham, P. L., Bidford, 10s.; Lloyd, Hugh, Machynlleth, 10s.; Pugh, John, Machynlleth, 10s.; Deynes, F., Newport Pagnell, 5s.; Fleming, A., Samford, £1; Elliston, W. A., Ipswich, 5s.; Edwards, G. E., Ipswich, 10s.; Manning, F., Samford, 10s.; Reynolds, R., Saffron, Waldon, 5s.; Wright, A. J., Caxton and Arrington, 5s.; Brooks, T. G., Caxton and Arrington, 5s.; Stamford and Felice, Launceston, 10s. 6d.; Rogers, G. O., Newport Pagnell, 5s.; Taylor, F., Woodstock, 10s. 6d.; White, J. G., Woodstock, 10s. 6d.; Collingwood, J. Bourne, 5s.; Gaye, W., Williton, 10s.; Crish, N., Wokingham, 10s.; Underhill, T., Dudley, 10s.; Clapham, J., Peterborough, 10s. 6d.; Perry, Ch., Aylsham, 5s.; Alderton, T., Aylsham, 5s.; Scarr, R. T., Bishop Stortford, 10s. 6d.; Meade, E., Tunstead and Happing 5s.; Francis, R., Felstead, 10s.; Wildash, H. C., Elham, 5s.; Rhys, W., Meath, £1.; Meree, W., Ticehurst, 10s.; Stawman, W., Barnsley, 5s.; Davies, F. C., Dolgelly, 5s.; Glover, J., Atcham, 5s.; Heaton, C., Leek, 7s.; Turnock, R., Leek, 7s.; Cooper, R., Leek, 7s.; Smith, W. B., Ticehurst, 5s.; Wilcock, C., Wareham, 5s.; Daniel, W., Wareham, 5s.; Williams, W., Wareham, 5s.; Prowse, W., Amersham, 5s.

Mr. Griffin has received the following:—

Bucknill, S. B., Rugby, 10s. 6d.; Fox, L. O., Stockbridge, 10s.; Turner, N. B., Sutton, &c., 5s.; Roe, R., Barton-on-Irwell, £1; Dorrning, D., Barton-on-Irwell, £1; O'Reilly, T., Ware, 10s.; Sedgwick, C., HOLLINGBOURNE, 10s.; Giles, W. F., New Forrest, £1 1s.; Rencraft, H., Southampton, 10s. 6d.; Cheeseman, G., Southampton, 10s. 6d.; Griffin-R. W. W., Southampton, 10s. 6d.; Lawrence, L. A., Southampton, 10s. 6d.; Diblin, T., Southampton (not union), 10s. 6d.; Tweddle, J., Cokermonth, 10s. 6d.; Nason, T. J., Stratford-on-Avon, 10s. 6d.; Nevin, J. B., Liverpool (not union), 10s. 6d.; J. W. F., 10s.; Taylor, H., Guildford, 10s.; Foster, O., Hitchin, 10s.; Colbourn, W. W., Chippenham, £1 7s.; Crisp, J., Chippenham, 5s.; Ludlow, A., Castlecombe, 10s.; Mackie, J., Darlington, 5s.; Clark, H., Sedgwick, 5s.; Clark, D., Durlam, 5s.; Lizard, H., Weymouth, 10s.; Brown, F. J., M.D. (not union), Rochester, £1 1s.; Shilliter, R. R., Hitchin, £1; Wilkin, J. F., Cranbrook, 5s.; Hernan, R., Tavistock, 5s.; Pearce, T., Tavistock, 5s.; Northey, W. C., Tavistock, 5s.; Reeves, W., Carlisle, £1; Doidge, J. G., Tavistock, 6s.

LETTER FROM THE PRESIDENT OF THE POOR-LAW BOARD.

Poor-l.w Board, Whitehall, 5th February, 1866.

SIR,—I am directed by Mr. Villiers to acknowledge the receipt of your letter of the 3rd inst., together with the draft of a proposed Bill "For the better Regulation of Medical Relief to the Poorer Classes in England and Wales," and I am to inform you that the provisions contained in the Bill shall receive the consideration of this Board.—I am, Sir, your very obedient servant,

JOHN THORNELY.

Richard Griffin, Esq.

ANDERSON'S UNIVERSITY.—A *pro re nata* meeting of the Trustees of Anderson's University was held on Tuesday in the Philosophical Society's Hall, when, out of the eighty-one, the whole number of the trustees, sixty-two were present. The object of the meeting was to appoint a Professor of the Practice of Medicine, in the room of Dr. J. B. Cowan, now Professor in the Glasgow University. The candidates for the chair were Dr. Thomas McCall Anderson, a relative of the founder of the University, and P. A. Simpson, M.D.—Mr. William Euing, President of the Managers of the University, on taking the chair, announced the object of the meeting, and read a letter from Dr. Simpson, who, in deference to the high professional talent of the other candidate, and the fact of his being a relative to the founder, requested that his name should be withdrawn from the list of candidates. The announcement was received with applause. Mr. Smith, of Jordanhill, then in warm terms proposed the appointment of Dr. Anderson, which was seconded by the Rev. Dr. Craik in a highly eulogistic speech. On a ballot being taken, Dr. Anderson was unanimously elected.

REPORT OF THE
COMMITTEE APPOINTED OCTOBER 18TH, 1864,
TO INQUIRE INTO THE
TREATMENT AND PREVENTION OF
VENEREAL DISEASES IN THE ARMY AND NAVY.

We learn from the *Lancet*, that the report of this Committee upon that part of their instructions which has reference to "any practical rules which the Committee can suggest to the military and naval authorities to diminish the frequency of the cases of contagion, and which are capable of adoption in the daily life of the ship or barrack," is now in the hands of the authorities, and has been privately circulated amongst a few of those persons who show an interest in the important subject. The loss of service arising from these diseases in the army in 1864 was equal to that of the whole force serving in the United Kingdom for an entire week. The daily loss of service in the navy (1862) was about that of 586 men per day. Besides, it must be considered that other secondary diseases arising from the same cause disable a number of the men, and that the permanent damage in health cannot be expressed in figures. Communications appended, from Sir Henry Storks and others, show that eminent success has attended preventive measures in Malta and in the Ionian Islands. The Committee find that the Contagious Diseases Prevention Act has in several respects been eminently successful. The unfortunate women with whom it has to deal are far from opposing its operation: they appear to appreciate its value, and magisterial interference has been the exception. Out of sixty-two witnesses examined, however, forty-four declared that the Act "did not go far enough," the remaining eighteen having no information on this branch of the subject. Sir Henry Storks showed that in the Ionian Islands, as the result of "careful and periodical inspection," the disease may be said to have almost disappeared; and so other witnesses as to other places.

The Committee recommend—the periodical inspection of all known prostitutes in the garrison towns placed under the provisions of the Act; the appointment of a surgeon for this purpose vested with all necessary powers; punishment for infringement of the Act; extension of its operation to all garrison and seaport towns in the kingdom where troops or ships of war are stationed; the prohibition of the residence of public women in beershops; that the Lock hospitals should be placed under Government control; and that the police supervision of the women in the streets of such towns be more stringent. They propose these amendments in the interests of public health and of the women themselves. They then consider the difficult subject of the periodical inspection of the men. A large amount of evidence has been brought before them showing the utility of such inspection, which, indeed, is self-evident; and the Duke of Cambridge, Mr. Trotter, Professor Longmore, and Sir Henry Storks bear strong practical testimony to its necessity. The Committee believe that by classification of the men (as to marriage, conduct, age, and so forth), and a careful method of conducting the inspection, it might be carried out without being offensive to the feelings of the men or of the medical officers. The most eminent civil witnesses were also unanimously of this opinion.

They further suggest increased facilities for ablation, and means of improving the moral and physical condition of the men: the fostering by Government of sailors' homes and savings banks. The Committee, however, point out that although they confidently believe the foregoing regulations would greatly reduce the amount of venereal disease amongst the men of the army and navy, yet they would leave untouched its introduction by the merchant sailors of our own and foreign navies—a matter involving so many important considerations that they only venture to call serious attention to it. It is signed, F. C. Skey (Chairman), B. G. Babington, T. Graham Balfour, M.D. (who dissents from many of the recommendations for reasons stated), Edward Cock, James Donnet, M.D., Richard Quain, Samuel Wilks, M.D., Spencer Smith (Secretary).

THE CHOLERA CONFERENCE.—This Conference was opened at Constantinople on the 13th inst., with an address from Aali Pasha. The regular sittings will begin on the Monday after the Bairam.

Medical News.

We regret to learn that Sir James Simpson has lost his daughter, aged 17. Miss Simpson died on the 15th inst. Since his baronetcy, barely a month ago, domestic affliction has been Professor Simpson's lot. In that short time he has had to mourn the untimely demise of his eldest son and this young daughter.

THE PISTOLGRAPH.—Under this name Mr. Skaife of Pall Mall, London, has designated an instantaneous method of taking photographs on glass, and which are suitable for being worn in a brooch or locket. The likeness is taken by means of the magnesium light, although this mode of illumination is not indispensable, and the resemblance to the original, as in photographs in general, is perfect.

THE SPECIFIC FOR CATTLE PLAGUE.—Mr. Maurice Worms of Ceylon has introduced a new cure for the cattle disease. It consists of shalot, garlic, ginger, assafœtida, and rice water, and is said to have been tried with success in Lord Leigh's and Sir A. Rothschild's herds.

UNIVERSITY COLLEGE HOSPITAL.—A contribution of £50 has been received from Mrs. Bishop, and another donation of £50 from Mr. Nathaniel Gould.

A PRIVATE letter from Hong Kong states that the immense mortality of the 11th Regiment, 82 dead and 200 invalided, was caused by the fact that the 11th, on their arrival at Hong Kong, were put in an old hulk, the *Hercules*, and then into sheds at Kaolwon, on the swampy mainland opposite Hong Kong. The 9th Regiment, however, who were in good barracks, also lost a great number. The disease which causes such frightful inroads there is called choleraic fever. Many civilians died of it during the winter months.

CHOLERA.—Cholera still lingers in Guadaloupe, and it is stated that one-fifth of the entire population of Basse-terre have fallen victims to the pestilence.

At the meeting of the Pathological Society of London, on the 6th inst., a most valuable collection of morbid specimens was exhibited.

MENTONE.—During the last five weeks the weather has been extraordinarily fine and mild, even for that favoured locality, old inhabitants bearing testimony to the unusual fineness of the season. The sun has shone day after day with increasing power, and not a sign of winter exists, to remind us of northern frosts and snows. So clear is the atmosphere that the outline of Corsica may often be seen on the horizon—most frequently before sunrise, but occasionally, as now, distinctly visible during the day. Corsica is distant about eighty miles. The visitors, especially English, are very numerous this season.—*The Cosmopolitan*.

THE HOLBORN UNION.—The Poor-law Board have had more cases of the disregard of the officers of this union reported to them.

A NOVEL SUTURE.—In a private letter from Dr. Chas. Dorat, Santa Anna, State of Salvador, Central America, he says:—"I will mention a curious case of native surgery I witnessed a short time ago. The patient had received a severe stab in the abdomen, from which protruded about half a yard of intestine and a portion of omentum, the former having a longitudinal slit about three inches long. On my arrival I found an Indian *medico* had sewed up the wounded gut with the nippers of a large ant. The insect, which is very savage, was taken by the body and its head presented to the united lips of the wound, which it bit and held fast. The operator then, by a pinch of the fingers, killed the ant, [nipping off its body and ?] leaving its head fixed to the gut. Another and another ant thus applied, to the number of a dozen or fifteen, effected this singular suture. The gut was then replaced, and, no inflammation ensuing, the man recovered speedily. This curious practice is said to be usual in this part of Central America."

HUNTERIAN SOCIETY.—On Wednesday evening, the 7th, the annual oration was delivered at the Society's rooms, by Mr. D. De Berdt Hovell, who, in his address, gave a comprehensive sketch of the modern practice of medicine as influenced by recent discoveries in science, and as viewed

in reference to the life and period of John Hunter. The dinner took place on Friday at the London Tavern, Alfred Smece, Esq., F.R.S., the retiring president, in the chair. Seventy gentlemen sat down to table, a larger number than usual, the president having specially invited several prominent members of the various learned, scientific, and art societies to meet the members of the Hunterian Society on this occasion.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A valuable and painfully-interesting collection of original drawings by the late Sir Charles Bell, which his widow has just presented to the country, through the Minister of War, is now on view in the museum of this institution, by permission of the Council, before being forwarded to the Royal Victoria Hospital at Netley. They are 17 in number of his large class drawings, illustrative of the terrible effects of war as exhibited in the soldiers wounded at the battle of Waterloo, and who had been taken into the churches and hospitals at Brussels, to which city Sir Charles Bell repaired and offered his professional services as soon as intelligence of the great victory reached England; and it was during his attendance on the wounded, French as well as English, that he had time to make these drawings, so valuable to the medical officers at our great military hospital at Netley, to which establishment they will be sent in the course of a week. By a singular coincidence, Mr. Wormald, the President of the College, has just discovered another series of 17 original drawings of anatomical subjects by Sir C. Bell, which he presented to the library of the College at the last meeting of the Council, and at the same time Sir William Fergusson presented another by John Bell, showing the nature of the wounds at the battle of Camperdown. The Council of the College of Surgeons has just presented to all the recognized provincial hospitals possessing libraries sets of the valuable illustrated catalogues of the museum, of the collective value of £690. The metropolitan hospitals and many learned and scientific societies, both at home and abroad, had previously experienced a similar act of collegiate liberality.

SICKNESS IN THE INDIAN ARMY.—Accounts from Bhootan report that the troops are very sickly in their present quarters. The 9th Native Infantry had 100 in hospital out of 600, after some weeks at Dewangiri, and the rest in proportion. Yet it is stated that these head quarters of dysentery are to be made a permanent infantry station.

THE POWERS OF THE CORONER.—Dr. Lankester has been astonishing the London police authorities by a brief exposition of his powers as a Coroner—powers, in most points, as extensive as those of the Chief Justice of the Queen's Bench, and in several points more so. An Inspector, under instructions from his Superintendent, who, in his turn, had been advised by the Chief Commissioner, refused to protect a surgeon who was making a post-mortem examination under the Coroner's precept. Dr. Lankester told the Inspector that if he so offended again he should commit him to prison; and he explained that he had power, not only to command the service of the police, but, if he found it necessary, to call out the military. His ordinary warrant, he said, was addressed to "all constables and others;" it was signed, in the name of the Queen; and any subject of the Queen, excepting some few of the higher Officers of the State could be called upon to assist in executing it.

POOR-LAW BOARD.—Dr. Edward Smith has been appointed Medical Officer of the Poor-law Board, in addition to the Office of Inspector of Poor-law. This appointment may be looked upon as evincing a desire, on the part of Mr. Villiers, to introduce the medical and sanitary element at the Board over which he presides. There was much need for such an appointment, but its value will really depend upon the degree in which the Poor-law Board avail themselves of it. At present the duties will probably be such, of a medical and sanitary nature, as the Board may think fit to refer to the medical officer; but in due time the office will, it is to be hoped, develop itself and occupy a position of both usefulness and prominence.—*Lancet*.

ST. PANCRAS WORKHOUSE.—A fresh outbreak of fever has occurred in this workhouse; four patients have been removed to the Fever Hospital.

TESTIMONIAL TO A SURGEON.—A public meeting was held on the 25th ult., at Milford, to present a testimonial to Mr. H. Byers, a surgeon of that place. Mr. Byers had been

upwards of fifty years in practice in that town, and had won the esteem and gratitude of all classes of persons. The testimonial consisted of a richly ornamented flower vase and a purse of one hundred sovereigns. There was a dinner in the evening, which was attended by a great number of gentlemen in the neighbourhood, the chair being occupied by Colonel Greville.

THE CHOLERA CONFERENCE.—Since our last the following further appointments to the approaching Cholera Conference have been announced:—Dr. Goodeve, to be the English medical colleague of the Hon. W. Stuart; Sahih Effendi, director of the Medical School at Koobarhané; and Dr. Bartoletti, member of the Board of Health, to represent the Porte; Drs. Pelikan and Bykow and Mr. Lintz to represent Prussia; Drs. Grissinger and Herch to be the Prussian representatives; and Dr. Salvatore, with the Chev. Vernoni, first dragoman of the Italian legation, to represent Italy. Dr. Goodeve, our own medical representative, has had great experience in India, and was strongly recommended to Lord Clarendon by the India Office as of exceptionally high qualification for this mission. He is expected to reach Constantinople by the Trieste steamer of Friday. Count Lallemand, the French representative, arrived by the Masselies packet of Sunday. The precise time for the opening of the Conference has not yet been fixed.—*Levant Herald*, Jan. 24.

BIRTHS and DEATHS Registered and METEOROLOGY during the Week ending Saturday, February 10, 1866, in the following large Towns:—

Boroughs, &c.	Estimated Population in middle of the Year 1866.	Persons to an Acre. (1866.)	Births registered during the week ending Feb. 10. Corrected Average Weekly Number.	Deaths.* Registered during the week ending Feb. 10.	Temperature of Air (Fahr.)			Rain Fall.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29.624 in. The atmospheric pressure rose to 29.91 in. on Sunday; and fell to 29.33 in. on Sunday.

The general directions of the wind was W.S.W., W., and S.W. * The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the 10 years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 45.1 deg.

MEDICAL DIARY OF THE WEEK.

- WEDNESDAY, FEB. 21.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Prof. Huxley, "On the Classification and Structure of the Mammalia."
HUNTERIAN SOCIETY.—7½ p.m. Council.—8 p.m. Mr. Hutchinson, "On Compression of the Brain."
- THURSDAY, FEB. 22.
ROYAL INSTITUTION.—3 p.m. Professor Tyndall, "On Heat."
- FRIDAY, FEB. 23.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Prof. Huxley, "On the Classification and Structure of the Mammalia."
ROYAL INSTITUTION.—8 p.m. Mr. William Pengelly, "On Kent's Cavern, Torquay."
- SATURDAY, FEB. 24.
ROYAL INSTITUTION.—3 p.m. Prof. Westmacott, "On Art Education, and how Works of Art should be viewed."

MEDICAL APPOINTMENTS.

[The Editors will feel obliged by receiving information respecting appointments as soon as possible after their being made.]

- BLAND, Mr. W. C., has been appointed Assistant to the House-Surgeon at the Huddersfield and Upper Agbrigg Infirmary.
- BURNS, R., M.R.C.S. Eng., has been appointed Resident-Surgeon to the Birmingham and Midland Counties Lying-in Hospital and Dispensary for the Diseases of Women and Children.
- BIRD, W. V., M.D., has been appointed Honorary Surgeon to the Bootle (Liverpool) Dispensary.
- FOSTER, BALTHAZAR W., M.D., M.R.C.P.L., has been elected Physician to the Birmingham General Dispensary.
- GENTLE, Dr. N., has been elected a Member of the Anthropological Society.
- HAMMOND, EDWARD, C., M.R.C.S. Eng., has been appointed Honorary Surgeon to the Wallace Dispensary, Egremont, Birkenhead.
- OLIPHANT, JOHN, M.D. Edin., has been appointed Junior House-Surgeon to the Northern Hospital, Liverpool.
- POCOCK, GAVIN E., M.R.C.S. Eng., has been appointed Consulting-Surgeon to the Brighton and Hove Dispensary.
- SANSKY, W. H. OCTAVIUS, M.D. Lond., has been appointed Lecturer on Mental Diseases in University College, London.
- KNOX, J., M.B., M.D., L.R.C.S. Ed., L.M., has been elected Physician and Surgeon to the Bakewell Dispensary, and Surgeon-Accoucheur to the Ladies' Charity, vice D. Knox, M.D., resigned.
- MAPLESON, H. T., M.R.C.S. E., has been elected Medical Officer in Ordinary to the St. Marylebone Provident Dispensary, Duke-street, Portland-place, vice J. Gayleard, M.R.C.S. E., resigned.
- MOUTAT, F., M.D., has been elected a Member of the Royal Institution of Great Britain.
- THORP, D., L.R.C.P. Ed., has been elected Resident Surgeon-Accoucheur at the General Dispensary, Birmingham, vice T. Holyoake, M.R.C.S. E., resigned.
- ANDERSON, T. McCALL, M.D. Glasg., has been elected Lecturer on the Practice of Medicine in Anderson's University, Glasgow.
- NEWETT, ROBERT H., L.R.C.S. Edin., has been elected House-Surgeon, and Superintendent of the Belfast General Hospital.
- KERRAS, R., L.R.C.P.L., has been elected Public Vaccinator, and Registrar of Births, Marriages, and Deaths, for the Banagher Dispensary District of the Parsonstown Union, King's County, vice W. B. Tarleton, L.R.C.S. I., deceased.
- LEVEY, J., M.D., has been elected Medical Officer to the Workhouse of the Balleborough Union, County Cavan, vice J. Taylor, L.F.P. & S. Glas., deceased.
- THORP, H., M.D., Consulting Physician to the Donegal District Lunatic Asylum, has been elected Medical Officer to the Letterkenny Union Workhouse, County Donegal, vice W. F. Grueber, M.R.C.S. E., deceased.

POOL-LAW VACANCIES.—RESIGNATIONS.

- Atcham Union.*—Alderbury District; area, 16,430; population, 2068; salary, £30.
- Fordeh Incorporation.*—The Fourth District; area, 8415; population, 3426; salary, £50. Workhouse, salary, £25.
- Sheffield Union.*—North District; population, 25,125; salary, £40.
- Thorne Union.*—Belton District; area, 8590; population, 1871; salary, £17.
- Tunnes Union.*—Dartmouth District; area, 200; population, 3176; salary, £17.
- Walsingham Union.*—Fakenham District; area, 12,530; population, 4655; salary, £52.
- North Staffordshire Infirmary.*—Office of Physician, vice Dr. Gooday. Election, March 21st. Candidate must be an M.D.
- Carmarthen Lunatic Asylum.*—Assistant Resident Medical Officer.—Salary, £100, with board and residence. Election, March 1st. Candidate must speak Welsh.
- Halloway Dispensary.*—Assistant Medical Officer.—Salary, £90. Election, February 28th.
- Chester General Infirmary.*—House-Surgeon.—Salary, £90. Election, March 28th.
- Lurgan Union.*—Moirs Dispensary.—Salary, £75. Election, February 28, 1866.

NOTICES TO CORRESPONDENTS.

Eblawensis.—We understand from very good authority that there is no truth in the statement (at least in the sense intended to be conveyed) that ten per cent. of the prisoners at the Pentonville establishment have been sent to the Broadmoor Lunatic Asylum. It is true that something like that proportion were told off some years ago to work as artificers at the construction of the buildings at Broadmoor, but they were not sent as inmates of the asylum, and the whole statement is therefore a *suggestio falsi*.

X.—We have not heard the names of any gentlemen eminent in the science as candidates for the appointment.

A Vestryman.—We conceive that the Medical Officer of Health only fulfilled his duty in making the report alluded to.

Dr. B.—In the case of paupers the certificate of one medical man is sufficient, but an examination by a magistrate must also be gone through.

Mr. H. G. D.—The subject is mentioned in another place.

Mr. Augustus S. Mayhew is thanked for the copy of his letter on the cattle plague, which, however, we have not room to insert. Many of Mr. Mayhew's facts are valuable, but we doubt the correctness of several of his inferences.

L.R.C.P. et S.I.—The letter has been received.

Mr. W.—The subject is under consideration.

Dr. J. T.—The paper has been received.

A Fellow.—There will be two vacancies at the next annual meeting.

BOOKS RECEIVED.

- Transactions of the Obstetrical Society of London. Vol. VII. Vegetable Charcoal; its Medicinal and Economic Properties. By James Bird, M.R.C.S. Hardwicke.
- Clinical Surgery. Part VI. By Thomas Bryant, F.R.C.S. Churchill and Sons.
- Photographs (Coloured from Life) of the Diseases of the Skin. Second Series. No. 1. By Alex. Hamilton Squire, M.B. Lond. Churchill and Sons.

MEDICAL AND SCIENTIFIC PUBLICATIONS.

- Braithwaite (William)—On Cholera: its Pathology and Treatment. 12mo. pp. 26, sewed, 6d. (Simpkin.)

BIRTHS.

- ASHWORTH.—At Market Overton, the wife of G. M. Ashforth, M.D., of a daughter.
- DAVIS.—At Croydon, the wife of Theodore Davis, jun., M.D., of a daughter.
- EAMES.—The wife of Dr. Eames, of H.M.S. *Gladiator*, of a daughter.
- HAMILTON.—At Liverpool, the wife of Robert Hamilton, F.R.C.S. Eng., of a daughter.
- LIVING.—At 52, Queen Anne-street, London, the wife of Edward Living, M.B., of a son.
- SIBLEY.—At 12, New Burlington-street, London, the wife of Septimus W. Sibley, F.R.C.S. Eng., of a daughter.
- TAYLOR.—At Ebury-street, the wife of Theophilus Taylor, M.R.C.S. Eng., of a daughter, still-born.
- THOMPSON.—At Westerham, Kent, the wife of Charles R. Thompson, M.R.C.S. Eng., of a son.
- WILLIAMSON.—On January 21, at Maryport, the wife of J. N. Williamson, M.D., of a daughter.
- FLEMING.—At Stranraer, N.B., the wife of Ebenezer Fleming, M.D., L.R.C.S. E., of a son.
- MOFFAT.—At Thornhall, Polmont, N.B., the wife of Robert Moffat, M.D., of a daughter.
- LITTLE.—January 28, at Lower Dominick-street, the wife of Dr. Little, of a son.
- MOORE.—January 31, at 67, Fitzwilliam-square, the wife of William Moore, Esq., M.D., of a son.

MARRIAGES.

- BROWN—GATES.—At Plumstead, Alfred G. Brown, M.R.C.S. Eng., to Emma Hodgson, only daughter of Charles Gates, Esq.
- GORSALL—GUEST.—At Warrington, John H. Gornall, M.R.C.S. Eng., to Mary, youngest daughter of the late John Guest, Esq.
- HAWKINS—HICK.—At Harpurhey, Manchester, Thomas Henry Hawkins, M.R.C.S. Eng., to Mary, daughter of the late B. Hick, Esq.
- MILES—BEDDOE.—In Hereford Cathedral, Edwin J. Miles, M.D., to Frances Anne, youngest daughter of John Beddoe, Esq.
- SHEPHERD—WYMER.—At Lowestoft, John Shepherd, M.R.C.S. Eng., to Fanny Olivia, youngest daughter of the Rev. E. Wymer.
- DAVIDSON—CAMPELL.—At Edinburgh, Robert H. Davidson, M.D., Deputy Inspector-General of Hospitals, to Burella Elizabeth, second daughter of Arthur Campbell, Esq.

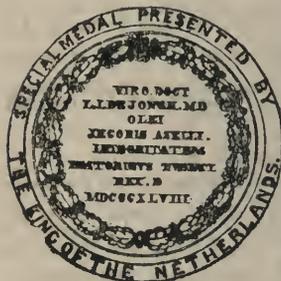

DEATHS.

- BHITTAIN, THOMAS L., M.D. Edin., House-Surgeon, General Infirmary, Chester, on February 1.
- BROWN, FREDERICK, M.D., at Benham Lodge, Newbury, on February 2, late 4th Dragoon Guards.
- GEISOW, Dr. F. L., at Frankfort-on-the-Maine, on February 5.
- GRAUB, FREDERICK F., M.R.C.S. Eng., at Faversham, on February 11.
- HAWTHORNE, ARTHUR, F.R.C.S. Eng., at Eccleshall, Staffs., on Jan. 28.
- JONES, WILLIAM, M.D. St. And., at Torquay, on February 6.
- RIDDELL, ROBERT F., at the Grove, Clapham-common, S., late Superintending Surgeon Hyderabad Contingent, on February 7.
- WARD, NATHANIEL, F.R.C.S. Eng., at the Ferns, Clapham-rise, on February 10.
- WILLIAMS, HENRY D., M.R.C.S. Eng., at Llanelfraid, Conway, North Wales, on February 6.

DR. DE JONGH'S

(Knight of the Order of Leopold of Belgium.)

Light-Brown Cod-Liver Oil.

The late Sir HENRY MARSH, Bart., M.D., Physician in Ordinary to the Queen in Ireland:—"I consider Dr. de Jongh's Light-Brown Cod-liver Oil to be a very pure Oil, not likely to create disgust, and a therapeutic agent of great value."

Dr. BARLOW, Physician to Guy's Hospital:—"I have been well satisfied with the effects of Dr. de Jongh's Cod-liver Oil, and believe it to be a very pure Oil, well fitted for those cases in which the use of that substance is indicated."

Dr. LANKESTER, F.R.S., late Lecturer on the Practice of Medicine, St. George's School of Medicine:—"I consider that the purity and genuineness of this Oil, are secured in its preparation by the personal attention of so good a chemist and intelligent a physician as Dr. de Jongh, who has also written the best Medical Treatise on the Oil with which I am acquainted. Hence I deem the Cod-liver Oil sold under his guarantee to be preferable to any other kind as regards genuineness and medicinal efficacy."

SOLE CONSIGNEES AND AGENTS,

ANSAR, HARFORD, & CO., 77, Strand, London, W.C.

Pulvis Jacobi ver, Newbery.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—I oz., 9s.; ¼ oz., 3s. 4d.

PHARMACEUTICAL PRODUCTS.

Prepared by Messrs. GRIMAULT & CO., Operative Chemists, 45, Rue Richelieu, Paris.

IODIZED SYRUP of HORSERADISH contains a considerable proportion of Iodine in a state of organic combination, which renders it, in many instances, the best substitute for Cod-liver Oil in cases where children and young females suffer from debility.

FERRUGINOUS SYRUP of QUINA, tonic, reparatory, and antichlorotic.

Dr. LERAS' PYROPHOSPHATE of IRON and SODA, the most agreeable and easily assimilable of Ferruginous Preparations, combining the principal elements of the Bones and Blood, Iron and Phosphorus.

SYRUP of HYPOPHOSPHITE of LIME.

SYRUP of HYPOPHOSPHITE of IRON; and

SYRUP of HYPOPHOSPHITE of SODA against all affections of the Lungs and Chest.

MATIOCO INJECTION and CAPSULES, New Preparations, of more certain effect than most of the Medicines recommended for the same class of diseases.

DIGESTIVE LOZENGES of LACTATE of SODA & MAGNESIA,

Prepared from the Recipe of Dr. PETREQUIN, by M. BURIN DU BUISSON, Operative Chemist, Laureate of the Imperial Academy of Paris.

The Alkaline Lactates, first recommended by the illustrious Professor Magendie, have been recently introduced into Medical Practice by Professor Pétrequin. The services they daily render have secured for them the foremost rank among the Medicines employed against Functional Derangements of the Digestive Organs. (See Dr. Pétrequin's Pamphlet on this subject.) May be had of all respectable Chemists, and of

Messrs. S. MAW & SON, 11, Aldersgate-street, London, E.C.,

who are the sole Wholesale Agents for the above and all other Preparations of Messrs. GRIMAULT and CO., Paris, for Great Britain and the Colonies.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

Before you purchase any Surgical, Mathematical, Philosophical, Surveying, or other instruments, send 3 postage stamps for each of Wm. Lawley's separate printed Catalogues of second-hand articles, and by purchasing you will save 40 per cent. A great variety of MICROSCOPES, TELESCOPES, and OPERA GLASSES, MAGIC and DISSOLVING VIEW LANTERNS, PHOTOGRAPHIC APPARATUS, CAMERAS, LENSES, &c., by the best makers. Address—78, Farringdon-street, City London.

Enlarged and Revised Illustrated Surgical Catalogue forwarded for six stamps.

NEWBERY'S NEW GLUTEN CAPSULES.

COPAIBA, COPAIBA AND CUBEBS, AND COPAIBA AND CITRATE OF IRON.

GLUTEN versus GELATINE. — GLUTEN AS AN ENVELOPE IMMEASURABLY SUPERIOR.

Beautifully made; egg shape.
Regular in size.
Contain no air-bubbles.

More convenient to take.
Smaller than those of other makers.
Though containing usual quantity.

Pleasanter in action.
Do not cause eructations.
If tried, will be approved.

Bottles of 36 Capsules, 2s. A liberal allowance to the Profession.

FRANCIS NEWBERY & SONS (Established A.D. 1746), 45, St. Paul's Churchyard, London, E.C.

BLOCKEY'S LONDON STOUT

NOURISHING LONDON STOUT.

DR. HASSALL'S REPORT. —

"I have carefully analyzed Blockey's

well known Stout, as obtained from 21, Duke-street, St. James's, and find it to be a genuine, most wholesome, and highly nourishing beverage, less heavy, and consequently more digestible than London Stout in general. Signed, ARTHUR HILL HASSALL, M. D. London, Analyst of 'The Lancet Sanitary Commission.' Casks of 4, 6, 9, and 18 gallons, at 1s 8d. per gallon; 3s. dozen pints; 5s. quarts.

RAGGETT, late Blockey, 21 Duke-street., St. James's. Established 100 years.

M. MASTERS, 210, New Kent Road, London, S.E.,

Patentee and Manufacturer of

ARTIFICIAL LIMBS AND SPRING CRUTCHES.

PRIZE MEDAL, INTERNATIONAL EXHIBITION, 1862.

EXTRACT FROM JUROR'S REPORT.—"For great ingenuity in the Contrivance, and for very great Excellence in the Manufacture, of Artificial Hands and Legs, and Apparatus connected therewith."

CASES OF INJURIES OF THE PELVIS:

WITH REMARKS.

By CHRISTOPHER FLEMING, M.D., F.R.C.S.I.,

SURGEON TO THE RICHMOND HOSPITAL, AND VISITING SURGEON TO STEEVENS' HOSPITAL.

INJURY OF THE PELVIS.—SEPARATION OF THE OSSA PUBIS AT THE SYMPHYSIS.—EXTENSIVE ECCHYMOISIS OVER THE PUBES, IN THE SCROTUM, AND IN THE PERINEUM, ACCOMPANIED WITH SIGNS OF EMPHYSEMA.

Case 1.—A little boy, aged 2 years, was crossing a roadway, when he came in contact with a dray and was thrown down. It was stated that one of the wheels passed over him, but his exact position at the time of the accident could not be ascertained; he got up, attempted to run, and immediately fell, when he was carried to the hospital. No injury of the extremities could be detected, neither was there any injury of the trunk discernible. Next day the child was again brought to the hospital, when considerable ecchymosis over the pubes, into the scrotum and the perineum, attracted attention. The accompanying swelling was very remarkable and prominent, especially over the site of the symphysis of the pubes. He passed water with pain, and with much difficulty, and it was free from any stain of blood. His bowels had also been spontaneously freed since the accident. He now lay heavy and listless in his mother's arms, had much fever, and could not tolerate the slightest movement of the pelvis or lower limbs. The tenderness over the pubes was extreme for some days, and in proportion to its subsidence and that of the ecchymosis, a distinct sulcus or inter-space, with unnatural mobility, was traceable in the site of the symphysis. About this period also, a remarkable crepitating feel over the seat of the extravasated blood was communicated to the fingers on pressure of the integuments around; this condition quickly subsided with the other symptoms, by rest and the ordinary antiphlogistic treatment. A pelvic bandage was subsequently applied, and after a fortnight the boy could not be prevented from moving about the ward, but it was yet obvious that his gait was shuffling and unsteady. Within a month, however, he had perfectly recovered from the accident and was brought home.

Perhaps the most instructive features connected with this case are, the extreme youth of the child, the presence of the peculiar emphysematous crepitation to which attention has been elsewhere directed, and the rapidity with which the effects of the accident passed off.

In the adult, the symptoms of such injury are to a certain extent equivocal, yet attention to details will enable the surgeon to form a tolerably accurate estimate of them. In the following case the displacement of the bones of the pelvis occurred at the symphysis pubis, and at the left sacro-iliac synchondrosis.

SEPARATION OF THE BONES OF THE PELVIS AT THE SYMPHYSIS PUBIS, AND AT THE LEFT SACRO-ILIAC SYNCHONDROSIS.—HÆMORRHIAGE FROM THE URETHRA.

Case 2.—A countryman, about 20 years of age, was assisting in pitching up hay on a large rick, and was the uppermost man, with his back to the rick, on a ladder used on such occasions, when, in the act of throwing up the hay, by some awkward movement he lost his footing, and fell on the pavement below from a height of twelve or fourteen feet. According to the account given, he fell obliquely, striking his left buttock in particular against

the ground. He was crippled up, and was unable to move, was carried home, and next day brought to the hospital in a cart. He had not passed water since the accident; he said he had some bleeding from the urethra, and complained of great tenderness and uneasiness about the left hip and the corresponding thigh and leg. He had also general febrile disturbance. On placing him in bed my first impression was that the left femur was fractured in some portion of its upper end, when, whilst endeavouring to adjust the pelvis for accurate measurement of the limbs, the unnatural mobility of the left os innominatum attracted attention. There was tenderness and considerable ecchymosis in the region of the pubes, and also over the tuberosity of the left ischium and corresponding side of the sacrum, but there was no crepitus nor any defect of moment in the general movements of the thigh on the pelvis. When lying steadily recumbent on his back he was free from uneasiness, but was intolerant of any disturbance of the pelvis. A yielding of the os innominatum on the left side, in the antero-posterior direction, was perceptible when pressure was made on the front of the bone, whilst pressure on the tuberosity of the ischium caused it to move in the vertical direction. At the symphysis there was much effusion of blood, with a decided irregularity and separation of the bones of the pubes; but there was so much pain on pressure that an accurate examination was impossible. The bladder was relieved, and as much steadiness of the pelvis was secured as could be accomplished with ease to the patient. The urine was free from blood. About the third day from the occurrence of the accident the integuments covering the left iliac and gluteal regions were very extensively ecchymosed. This condition, however, with the attendant fever, gradually subsided, the bladder quickly recovered its functions, the bowels acted satisfactorily, and after two months' confinement with a pelvic bandage, and with the limb adjusted in the extended position as for fractured thigh, the man was removed from the hospital with every prospect of complete recovery, he being at the time enabled to go about on crutches. With their assistance he could then move with tolerable freedom, no appreciable displacement of the left side of the pelvis being traceable, nor any alteration in the position or direction of the limbs being perceptible.

The opportunity afforded for ascertaining the effects of the absolute injury inflicted in the following case renders it worthy of record; and this is, perhaps, the more desirable, as the causes of such mischief are now comparatively unfrequent.

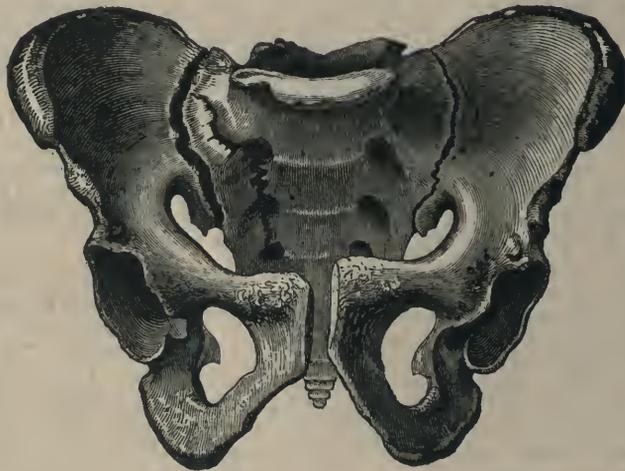

FORCIBLE SEPARATION OF THE BONES OF THE PELVIS AT THE SYMPHYSIS PUBIS, WITH PARTIAL DISJUNCTION AT BOTH SACRO-ILIAC SYNCHONDROSES.—VERTICAL FISSURE THROUGH THE BODY OF THE SACRUM.—LACERATION OF THE BLADDER AND OF THE URETHRA.

Case 3.—A labouring man, beyond 60 years of age, was employed in undermining one of the side walls of a house in the neighbourhood of the Richmond Hospital, when, in the act of stooping forward, the wall gave way, and he was crushed beneath it. He was, with much difficulty, removed from under the rubbish, and was brought to the hospital some hours afterwards, sick and faint, groaning with agony, and totally powerless. When undressed, extensive ecchymosis was visible over the regions of the pubes and sacrum; blood was flowing from the urethra, and was effused under the integuments of the penis and scrotum, and, moreover, distended the left inguinal canal, so as to resemble a hernia in that situation. Every, the slightest movement, of the lower limbs gave pain, but the principal suffering was referred to the region of the bladder, and to the symphysis of the pubes, in the latter of which situations the tenderness was so extreme that the slightest pressure could not be borne. The symmetrical relations of the pelvis and the lower extremities were, as far as could be ascertained, unimpaired, and their motor powers and tactile sensations were tolerably perfect. The immediate treatment had reference chiefly

to the state of collapse present, and to the allaying of pain. Subsequently, it became necessary to relieve retention of urine by the introduction of a catheter, which, after some slight obstruction about the region of the bulb, reached the bladder, and gave exit to urine, in amount about four ounces, and perfectly free from any tinge of blood. The lower region of the abdomen gradually became swollen and tympanitic, the ecchymosis increased in extent, and crepitation of air was distinctly traceable under the surrounding integuments. Any attempt to change the poor man from the horizontal posture on his back produced agonizing pain, and he could not bear the slightest movement of his limbs on the pelvis. Reaction was never restored; his restlessness increased; his countenance became pallid and haggard, and he sank with all the symptoms of internal hæmorrhage in about forty-eight hours after the accident. A post-mortem was obtained with much difficulty, when the ecchymosis, tympanitis, and emphysema noted in the history of the case were found to occupy the hypogastric, the iliac, and the inguinal regions, and to extend to the left inguinal canal. On the left side of the symphysis pubis a distinct projection was felt, the points of the fingers sinking into a hollow along its inner margin. The walls of the abdomen being perforated in the hypogastrum, a quantity of air devoid of any fœtid odour escaped, and now, its cavity being opened, the spaces intervening between the walls and the peritoneum in that region were found to be largely infiltrated with blood. This was also traceable between the muscles, especially near the symphysis pubis, and was continuous with that effused into the left inguinal canal, and into the cavity of the pelvis. There was a distinct separation of the bones of the pelvis at the symphysis pubis, the left horizontal ramus being on a plane considerably above and

behind that of the right, and a thin scale of bone being detached from it—firmly adherent to the intervening fibrous structure. There was a deep sulcus stained with blood between the true ligaments of the bladder, and, on tracing the anterior wall of that viscus, a vertical rent was found in it, somewhat about a quarter of an inch in extent, anterior to the reflexion of its peritoneal coat; the edges of the rent lying so closely applied to each other, that it was only discoverable by the escape of bubbles of air from within the cavity of the bladder, when it was compressed. The bladder contained from two to three ounces of urine, untinged with blood; but around it, and towards the rectum, there was a great amount of blood effused external to the peritoneum. The ecchymosed and lacerated state of the perinæum and scrotum rendered it utterly impossible to insulate the urethra, it being apparently torn across in its membranous portion. On proceeding to remove the pelvis, the additional lesion of a partial separation of its bones was found at each sacro-iliac synchondrosis, and also a vertical fissure extending through the right side of the body of the sacrum. The bladder and the pelvis were removed, and in the accompanying excellent delineation, by Mr. Oldham, the separation of the symphysis pubis, the consequent disarrangement of its bones and its arch, the disjunction of the sacro-iliac articulations, and the fracture in the sacrum alluded to, are each distinctly shown. The occurrence of retention of urine, and of the wound in the bladder, without the presence of hæmaturia, are not the least interesting features connected with the case; the latter of which may perhaps admit of explanation on anatomical grounds, from the peculiarity of distribution of the arterial supply to that viscus. There was no trace of inflammatory action in the peritoneum, or elsewhere.

With reference to injuries of the pelvis in general, it may be remarked, that the diagnosis of the special lesions which its several parts may have suffered is frequently involved in obscurity, and that the attempt at too accurate an adjustment of their attendant displacements is often extremely questionable. As in certain cases of fractures of the ribs, mechanical compression of the thorax cannot be tolerated, so likewise in fractures or other injuries of the pelvis, the agony resulting from the adoption of any

constrained provision for adjustment is frequently extreme, and its advantages are very questionable. In such cases, I believe that if attention be paid to the proper position of the pelvis, measured by its symmetrical relations to the lower extremities, all that is desirable in local treatment will be accomplished. Too much anxiety to detect the crepitus of fractures on the one hand, or, on the other, to remedy any accompanying deformity, may be followed by consequences of a fatal character—such, for example,

as uncontrollable hæmorrhage, or additional injury to the viscera contained within its cavity. A certain amount of deformity must be submitted to. It is unnecessary to particularise further, as the cases recorded will, it is hoped, be found sufficiently explanatory. They severally tend to illustrate the different effects of violence applied to the bladder and the urethra in those injuries, the obstructions which the current of the urine through the latter may or may not have to experience, and the modes whereby relief may be afforded. Be the effects merely contusion, or be they fractures, or displacement of the bones, accompanied or not by laceration of important organs, they severally demand the greatest caution in treatment. Attention to symptoms will teach the surgeon the impropriety of unnecessary operative interference in one class of cases, and the great value of promptness of action in another. An urgent desire to pass water is often

amongst the immediate symptoms attendant on the more severe of those accidents involving the bladder or urethra, and hence the very great hazard attending them. In many such cases, however, the areolar tissue surrounding the seat of the lesion becomes almost instantaneously injected with blood, and thus a protection is, as it were, given to that tissue; the relations of it to the rent in the bladder or the urethra are, moreover, altered, and so the injurious effects of the urine, which may happen to have been extravasated, are materially modified. The satisfactory issue of the case, where, undoubtedly, urine had escaped through the torn urethra, is by no means an unfrequent occurrence, and that of the torn bladder, is most instructive. It is important to bear in mind the possible complication of laceration of the urethra or of the bladder with such injuries, and the deceptive characters of the accompanying symptoms; the most accurate diagnosis, both absolute and

differential, is hence required, whereby the surgeon will be prepared for the perplexing contingencies which he may have to contend with. In many of the periodicals of the past and the present day most complicated cases of that class are recorded on unquestionable authority, whose favourable results have ensued which never could have been calculated upon. The extensive extravasations of blood so often present, the varied periods at which such extravasations may manifest themselves, and the occasional peculiarities which may accompany them, are not unimportant practical considerations for the surgeon, and are well deserving his attentive investigation.

ON CHOLERA AND CHOLERAIC DIARRHŒA.

By J. R. GREENWAY, L.R.C.P.Ed., Sandy, Bedfordshire.

DIARRHŒA of a severe character, and in several instances attended with choleraic symptoms, prevailed to a great extent in this neighbourhood during the latter part of August and the month of September last. The majority of cases were male adults, residents of the district, which is badly drained. One case of cholera, and the only true case of this disease I am aware of, that occurred within a few miles of the same locality during the epidemic referred to, I would specially mention. Other cases reported to be such came under my notice, but since the very name of cholera carries with it alarm, I fear this fact has too often been taken advantage of by some medical men over anxious (I presume) to establish a reputation, calling disease by the name, yet wanting all the severe characteristics of this dangerous malady. I regret to say that in several instances I have found such to be the case. Early on the 28th of August I was summoned to visit a farmer, distant four miles in the country, by the message, "come immediately, he must have the cholera and is dying." Not being a stranger to such a message during the epidemic, I questioned in my own mind the gravity of the case; but on reaching the patient I at once marked his ghastly aspect, extreme restlessness, livid and clammy skin, and the peculiar effluvia arising from the body. The patient was 31 years of age, had previously enjoyed good health, was a well-developed muscular man, and had led an active industrious life; he had not recently been away from the district. On the night preceding the day I saw him, diarrhœa symptoms were troublesome, and these gradually increased in severity; the pain which ushered in the attack subsided, but violent cramp in each extremity ensued, attended by retching and vomiting, and alvine evacuations more and more constant and profuse, in appearance resembling rice water; the extremities were livid and cold, but the patient complained of being oppressively warm; the pulse was slightly perceptible, but could not be counted; the tongue dry and covered with a brown fur, thirst excessive and constant, the pupils dilated, urine suppressed, a low hoarse voice, and restless uneasiness, made up the state in which I saw the patient. There could be no mistaking this man to be stricken with cholera in the worst of forms it visits our island.

The objects I had in view, and the treatment I carried out to fulfil these objects, I shall briefly state, in order that should such stand the test of experience it may be useful to others; if not, these remarks will not have been lost should they call forth that criticism the treatment of such diseases justly demands.

Regarding cholera and choleraic diarrhœa symptomatic of a poisoned blood condition, by which symptoms nature is manifesting every effort in her power to get rid of the enemy, but in the above-named case was well nigh exhausted in the struggle—I at first endeavoured to relieve, if possible, the more urgent symptoms of the case—viz.,

1. To rouse the vital powers from their collapsed condition.
2. To check the retching and vomiting, and the no less constant action of the bowels.
3. To relieve the cramp and spasm, in my opinion the

reflex symptoms of an irritated intestinal canal performing excessive functions induced by the depraved blood condition.

I prescribed the following treatment, waiting a time with the patient to see my orders implicitly carried out. Strong brandy and water was given and rejected. The patient was surrounded by blankets; bottles of hot water were applied to the feet, bags of hot bran to the inside of thighs, hot bran poultices sprinkled over with turpentine to the bowels and cardiac region, and these applications frequently renewed. The following mixture I prepared before visiting the case and took with me:—

℞ Calcis saccharatæ, ℥iij.*
Sp. chloroformi, ℥iv. (pars. i., ad. ix.)
Tincturæ opii, ℥j.
Tincturæ lavand. comp. ℥j.
Aq. ad. ℥vj. Miscæ.

One tablespoonful to be taken in as much water, as often as directed.

The first dose was rejected; after a few minutes another dose was given and retained; the medicine was then directed to be given every hour, but in case the vomiting returned a dose to be given a few minutes afterwards, and so repeated if necessary.

Nourishment and stimulants being indicated, they were given, as soon as they could be borne, in the following manner:—Two tablespoonfuls of brandy to be mixed with half a pint of cold water, to be given by spoonfuls as often as agreeable, to relieve the patient's distressing thirst; a larger quantity or stronger preparation invariably induced a return of the vomiting. After a few hours the vomiting was much less frequent, but the other symptoms had scarcely improved. Taking advantage of the improving gastric condition, milk thickened with corn flour, to which a little lime-water was added, was frequently administered by spoonful doses. By nine p.m. all remedies exhibited were retained, except upon one occasion, when the patient also vomited about two ounces of a dark coffee-coloured fluid, and afterwards seemed less restless, and the cramp was less constant and severe. He still complained of insatiable thirst, which, no doubt, ice would have relieved had it been procurable, though I consider it might prove a very depressing agent in the early stage of the disease. Raw eggs were ordered to be beaten up with the milk food.

August 29th: This morning the aspect of the patient indicated improvement. Retching and vomiting had ceased, alvine evacuations much less constant, pulse rallying, and symptoms generally improving. Plenty of albuminoid food was ordered, in the form of eggs beaten up with warm milk and a little brandy added.

30th: The patient has slept a short time during the night, and early this morning passed a small quantity of urine abounding in phosphates; the lividity of skin disappearing, bowels open only four times during the day and night; pupils contracting; pulse very frequent and feeble; thirst less troublesome; temperature of body increasing; cheeks flushed. The patient says upon the whole he feels comfortable, but still feels faint, and is occasionally troubled with fits of cramp. Diet to consist chiefly of farinaceous articles made up with raw eggs, beef-tea to be given twice during the day, the brandy-and-water to be made weaker and administered less frequently. On the 4th and following day the bowels were open twice; in other respects, the symptoms were more of a typhoid character. Strong beef-tea and the farinaceous food, as before described, with the addition of brandy, was ordered to be frequently administered in small quantities, and the following mixture prescribed:—

℞ Liq. ferri perchlorid. ℥i.
Sp. chloroformi, ℥iiss. (i. ad. ix.)
Tincturæ opii, ℥xl.
Aq. ℥viiss. Miscæ.

Two tablespoonfuls to be taken three or four times a day,

* Prepared by General Apothecaries' Company, Berners-street, London.

which was given till the patient was able to resume his usual duties, who continued henceforth daily improving, and walked out of doors on the eleventh day, though contrary to my injunctions.

In several cases of severe diarrhoea with choleraic symptoms, as cramp, clammy skin, prostration, vomiting, and profuse evacuations, the latter presented a yeasty rather than a rice-water character. In two cases there was marked lividity of skin, but the pulse was distinct though feeble, and there was pain more or less severe in the bowels; the aspect and effluvia peculiar to cholera cases were wanting; the urine was not suppressed; thirst less distressing, and reaction commenced after a few hours, and the symptoms rapidly improved under the treatment adopted, which was similar to that prescribed in the cholera case, modified according to the severity of the attack. In all the cases disinfectants were supplied to be exposed in each patient's room, and the least objectionable and most serviceable preparation of this character that was used was the "deodorizing powder," prepared by the General Apothecaries' Company, Berner's-street, Oxford-street, London. After the severity of the attack was over, the patient was advised to change his room and bedding, and everything belonging to the sick rooms was exposed out of doors, and, when practicable, washed or cleansed, and the room left open to currents of air for two or three days; and in no single instance did any serious attack of gastric or intestinal derangement affect any of the attendants.

In the majority of cases in which I was consulted during the epidemic, the mixture containing calx. sacchar. sp. chloroform., &c., checked the sickness and diarrhoea after two or three doses had been exhibited, and effected a cure in from twenty-four to forty-eight hours, and no death came under my notice. In a few cases presenting an after-state of debility requiring medical treatment, a chalybeate mixture, containing pernitrate of iron and chloroform, seemed very beneficial in restoring the patient's strength. In most cases, after the first twenty-four hours, the bowels were constipated for two or three days, but acted naturally after that time without the aid of aperient medicine.

In mentioning what was evidently the cause of the epidemic referred to, I must explain that large quantities of manure constantly arrive in this neighbourhood from London about the time of year named. This year the manure so sent was highly offensive, and abounded in putrid animal substances, some of it evidently animals that had been a prey to an existing epidemic, even large portions of flesh and limbs, and entrails of bullocks in a putrescent state could be seen in the railway manure trucks, and was thence carted along the roads to the neighbouring fields. My suggestions influenced a neighbouring M.P. to kindly take steps to suppress the nuisance, and on manure containing such pernicious matters being forbidden by the conveying companies, the health of the district from that time improved, and such diseases ceased to occur, along with diseases of an indefinable name, but manifesting much gastric derangement, with retching or vomiting, loss of appetite, clammy skin, and prostration, and, in some instances, accompanied by a pustular eruption. Two cases which came under my notice are worth citing, as these symptoms disappeared on change of air, and returned the day following the patient's return to this neighbourhood. I am, therefore, disposed to infer that there is no specific medicine for the diseases in question; but that in prevention and cure medicine must ever be subservient to duly enforced hygienic measures, and with this proviso I have found the remedies cited effective collateral aids.

Simple diarrhoea is generally very prevalent here early in the autumn. Little fruit is grown; but at that season decaying vegetable matter everywhere abounds, though during the few years I have resided in the neighbourhood I have not during any former year seen a single instance of its manifesting a choleraic tendency.

RETROSPECT OF THE JOURNALS.

THE *Medical Times and Gazette*, under the head of a "novel phase of medicine," draws attention in a very satirical tone to the position of surgeon to a railway company as revealed a few days since in the trial of "Meaken v. Midland Railway." The surgeon mixes a little business with his profession, and endeavours to act as mediator. In the case in question he acknowledged to having carried cheques about with him for the purpose of effecting a settlement.

Under the head of "Thermometer in Disease," cases are related showing the value it affords as a means of diagnosis. The variance of temperature is, however, so small that it will hardly come much into fashion, being so liable to error.

Dr. Richardson's instrument for producing local anaesthesia is being used extensively and successfully in minor operations. It is to be regretted that the instrument has been patented.

M. Le Fort, treating of the mortality of lying-in women, has found that one death occurs in thirty cases delivered in hospital, but that one in one hundred and fifty or two hundred represents the mortality among women delivered at their own homes:—

"On the occasion of the presentation of M. Le Fort's work to the Academy of Sciences, General Morin observed that the Consulting Hospital Committee of the Ministry of the Interior had been occupied with this question, and had arrived at the same conclusion as M. Le Fort's figures led to, that it was preferable that women should be delivered *à domicile*; but, as many of these women had no homes, it was impossible, even for their sakes, that maternities should be suppressed. The most that could be done was to ameliorate their condition by diminishing the number of beds, and very much enlarging the space occupied by each. The plan, too, found so efficacious at Dublin will also be adopted—viz., the assigning four wards, each capable of holding ten beds, to thirty patients, so that there shall always be an empty ward, which, in its turn, is cleansed and whitewashed. He added that public opinion had suffered a great shock from this frightful mortality at lying-in-establishments, and that it was very important that it should be made acquainted with the solicitude with which the administration was endeavouring to remedy so sad a state of things."

The *British Medical Journal* refers to Dr. Richardson's new method for producing local anaesthesia. Continued success attends the use of his instrument, and it may fairly be looked on as an accomplished fact. There will be some difficulty in procuring the ether as pure as is necessary, but it is a rule that where there is a demand there will be a supply. We may anticipate that in future there will be fewer cases of death from chloroform, as these generally occur after minor surgical operations.

Dr. Chambers gives some details of 257 cases of rheumatic fever, some of which were treated without medicines, and these were discharged from hospital after a shorter sojourn than any of the others in which drugs were administered.

Dr. G. Johnstone gives a paper on the "physiological correlation of the lungs, liver, and kidneys, as illustrated by the phenomena of choleraic collapse."

From Middlesex Hospital three cases of diphtheria are related, in which tracheotomy was performed. They proved unsuccessful. One of the cases after death was subjected to the Cæsarean section, but ineffectually.

A very valuable and interesting paper on the sanitary condition of England during the middle ages is given by Dr. Russell. Our forefathers certainly had not much to be thankful for in the way of domiciles. The paper was read before the University Graduates Club at Birmingham.

The widow of the late Sir Charles Bell has given a most valuable collection of sketches of gun-shot wounds and injuries as a presentation to Netley Hospital. The sketches are highly interesting, as having been done in Brussels by the great surgeon himself, immediately after Waterloo.

Proceedings of Societies.

HARVEIAN SOCIETY OF LONDON.

Dr. TYLER SMITH, President.

Dr. DRYSDALE exhibited to the Society

A CASE OF SYPHILITIC IRITIS,

which had been treated with the simplest means and without specifics. The patient, a young man, aged 20, had come to the Farringdon Dispensary on January 1st with a bad attack of iritis in the right eye. He was covered from head to foot with a papular syphilitic eruption. There was at that time circumorbital pain, pink zone around the pupil, great effusion of lymph and irregularity of the pupil, with complete absence of vision. A drop of solution of sulphate of atropia (gr. j. ad. ʒj.) was directed to be dropped into the eye twice a day, and he was told to take a purge in the morning. No shade for the eye nor any other specific treatment was ordered. In about a week the lymph was absorbed, and at the end of the third week (although contrary to Dr. Drysdale's orders) the patient worked at his occupation as a printer. This case was one of several he had successfully treated in a similar manner. Williams of Boston, Carmichael of Dublin, Hughes Bennett, and J. Z. Laurence, had shown how needless the injection of mercury or salivation was in such cases, as in all other inflammations.

Mr. DE MERIC observed that many persons who treated syphilis without mercury had observed that the eye disease bore a great resemblance to the skin eruption, and was therefore, they thought, likely to do as well as the latter without the mineral. He thought that the experience of the past as to the value of mercury in iritis ought not to be disregarded, and believed that, although *this* case was successful, it might have turned out quite the reverse, and thus we were not justified in making experiments in hospitals and dispensaries when the chances were against us.

Mr. JAMES LANE thought that there was great variety in cases of syphilitic iritis, and that each particular case should be treated on its own merits. Thus in some cases mercury was not required, whilst in others it was a valuable agent, although he thought that its use had been too much erected into a dogma.

Dr. DRYSDALE said that Mr. de Méric's argument was one of the order of oratorical or *ad captandum* appeals: it did not touch the question. Of course any medical man who would treat a poor patient differently from the way in which he would himself desire to be treated, was unworthy to carry on his important social functions. The question was not to be evaded by such fallacious appeals to popular prejudices, but must be met by facts such as those he had just brought before the Society. He did hope before long that many of the ophthalmic specialists of London and elsewhere would try to do without so empiric a treatment as mercury in iritis. By so doing they would, he believed, advance medical science, and do more good to persons with iritis.

Mr DE MERIC read a paper

ON SYPHILISATION,

in which he combated the practice. The chief aim of the author was to show that the *rationale* of the numerous inoculations to cure syphilis was defective, that this peculiar method of treatment was not superior to those already known, and was fraught with extreme inconvenience. To render the subject quite intelligible, he attempted a historical sketch of the rise and progress of the practice, dwelling especially on Auzias-Turenne, the originator, and Sperino and Boeck, the warm promoters. He then con-

tended that the term syphilisation was erroneous, as the patients were already syphilised by the constitutional complaint, and endeavoured to show that the improvement noticed was quite independent of the inoculations, which latter he considered cruel and useless. After alluding to the unfavourable effects of the practice upon the moral tone of the girls experimented upon, he agreed that the trials lately made at the Lock Hospital were quite in the spirit of fair play, and regretted that Auzias had met with denial at Paris when he wished to try his method in the hospital for female delinquents. Mr. de Méric concluded by complimenting all those concerned on the tone of moderation and forbearance that had hitherto marked the discussions on the subject.

Mr. GASCOYEN said it might have been conjectured that, in bringing forward the subject of syphilisation at the present time, Mr. de Méric was animated by a desire of giving an opportunity to those who had taken an interest in the subject of producing their experience; but there was no mistaking the intention of the present paper: it was an attack on the practice of syphilisation. Now, although the short time elapsed since its introduction into this country did not seem to warrant any strong expression as to the success of the method, yet there had been more than time enough to form an opinion as to the amount of reliance we should accord to the teaching of the French school when syphilis, and especially syphilisation, is its theme. It is now fifteen years and more since the latter subject had been mooted in Paris, and what do we find in the most recent productions of the French press concerning it? Nothing but a repetition of the most wilful misstatements and the vilest caricature. First in order stands that stupendous assertion that matter from soft chancres is inoculable *ad infinitum*. In the experiments, as Mr. de Méric is pleased to call them, under progress at the Lock, the soft chancre is very commonly carried through a series of 8 to 12 generations, more rarely as many as 20, and only once has a series of 30 been obtained. It is true that in his large sphere of practice at Christiania, Dr. Boeck once got 83 from matter of an uncommon character and quality. Opposed to this experience in every modern French treatise on syphilis, in Aimé Martin's Manual, and in the latest work on the subject, that of M. Rollet, we find repeated the same idle tale of a German physician who inoculated himself with 2200 chancres, and after this he ceased to count, but still went on inoculating for ever and a day: the body of the poor man was seamed with scars, and his syphilis was unrelieved. Now, this story is a mere fable, but as it seems to serve their purpose they keep it going. Indeed there is good reason for believing that when Ricord framed this dogma of the perpetual inoculability of the soft chancre, he only knew of a series of eight having been obtained, but subsequently, as he affirms, he inoculated 1900 chancres on the body of one of his students, without witnessing any change in the character of the inoculations or condition of the patient. This story is equally incredible with the other, and only possible if, as is stated to have been the case, Ricord blotted out the inoculations with caustic soon or immediately after they had been made. Dr. Boeck, who cordially admires the man, says it was not openhearted of Ricord to publish the fact without divulging the method, and the speaker certainly thought so too. In discussing Dr. Boeck's practice, among other misstatements, M. Rollet, restricting the practice of Boeck to the use of matter from soft chancre, goes on to say that such treatment is not isopathic, but indeed in a high degree antagonistic. M. Rollet carries dualism as far as that. Well, if that be so, if it be really antagonistic, there is a *rationale* of treatment at once; but no advocate of syphilisation ever ventured on so bold an explanation as this of M. Rollet. These men are blinded by their prejudices and so far lost to reason. The speaker then quoted Victor Hugo, as to the influence of French thought in Europe, and how the French prided themselves on such conquests; if, the speaker said, they wished to make their

conquests permanent they must keep themselves allied with truth. There was no more disgraceful page in the history of science or of society, than the treatment of Messrs. Auzias and Sperino by the Academies of Paris and Turin, in support of certain interests predominant in those cities or intriguing there. These two gentlemen have been made the subject of the grossest calumnies and misrepresentations. In the present hour there is no one who does not accord to them the title of honourable men. But who is to make them amends for the past? What was the crime of M. Auzias-Turanne? No other than that he succeeded in doing that which Messrs. Ricord and Cullerier had failed in accomplishing—viz. the inoculation of chancres on the brute creation, now received as an acknowledged fact in science. When M. Auzias had further observed that these inoculations were limited in the individual, both as to number and significance, there arose out of this discovery suggestions of the most obvious application and character, which were the property of all Europe; and Signor Sperino, highly experienced as he was in the treatment of syphilis, availed himself of the discovery simultaneously with M. Auzias, and quite independently of him. In both instances, however, the most violent persecution was brought to bear against the pursuit and development of science, originally in Paris, and afterwards at Turin, in humble imitation of Paris. At least no one has accused Dr. Boeck with not being a decent man. It is a significant fact that only within a few months have we in London known anything about syphilisation. Dr. Boeck's visit to England was not, perhaps, strictly of a voluntary and extemporised character. He lived under the impress of great truths which are vital to the well-being of our community. Like many foreigners, he seems to have entertained the idea that we are a practical people, and not insensible to personal merit. In London it is certain his success has not been great. After he had resided here for three or four months, two or three assistant surgeons of hospitals began to have a little faith in the treatment and some inkling as to the merit of the introducer, but as this feeling was not supported by any amount of attentive observation or strengthened by reflection and inquiry, the thing broke down upon the very first difficulty, and now there is only one small hospital in the suburbs where the treatment is continued. There is little excuse, therefore, to sound the alarm. In the paper we had listened to there was a certain show of argument with a strong admixture of wit. A clever pen would handle any subject in that manner. We see enough of that in the *Saturday Review*. But the duty of physicians is more serious. The word syphiliser, or syphilisator, is none of our seeking or accepting: it has grown out of a coarse attempt to place the infecting person and the physician on one and the same level. Referring to early experience, the speaker said his very first lesson in physic was in dealing with essential fevers, erysipelas, scarlatina, and small-pox: these diseases, he was rightly taught, were incurable, but by helping the patients through them he had saved many lives. So with syphilis, what we pretend is to help the patient through with it. We find a man with syphilis, and we give him more of it. Yes, that is also true; we find him perplexed and suffering man; we leave him a healthy and a confident man. Mr. de Méric denies the fact that we do syphilise the patient, on the ground that if we did so his eruption would extend and increase under the inoculations. Now, in fact, the eruption does so behave in a large proportion of cases before it begins to fade away. It has also been objected that syphilisation is a painful process. We do not deny that there is some amount of pain. This depends much on the selection of the matter; some matter will give pain, other kinds give but little or no pain. It is objected that the immunity obtained is not perfect, and then again that immunity is highly improper, because it fits the patient for the *postribulum*. Turn either way, we catch it on both sides, but to all these objections we can find sufficient answers.

Mr. JAMES LANE said he had listened with great atten-

tion to Mr. de Méric's interesting paper. He thought, however, it must be evident to all who heard it, that he spoke in the character of a determined opponent of syphilisation, rather than of a calm inquirer into its real merits. Mr. de Méric had expressed regret that individuals should have been found in this country ready to "march under the banner of Professor Boeck," and to afford a footing here to the practice of syphilisation. He (Mr. Lane), speaking for himself and his colleagues at the Lock Hospital, wished to say that they were not marching under anybody's banner; they had initiated the present inquiry, and had followed it up as far as their limited opportunities permitted, because they could not help seeing that syphilisation had attained such a degree of importance in other countries that it was high time the profession in England had an opportunity of forming an impartial judgment about it. They had approached the subject in a perfectly impartial spirit, and for himself he could truly say that he was entirely unbiassed by anything except what he had seen with his own eyes. It was important that the Society should not be led by Mr. de Méric's paper to lose sight of the real question at issue respecting syphilisation. It was briefly this:—The method had been practised abroad to a large extent, and in Norway more especially very important results were alleged to have been obtained, by men of high scientific attainments, whose good faith no one ventured to call in question. They told us that inoculation would cure constitutional syphilis with greater certainty than any method hitherto known, and would be attended not only with a smaller number of relapses, but that the relapses which did occur would be only of a trivial character, and would usually disappear of themselves without further treatment. Now, was the treatment of syphilis ordinarily pursued, whether mercurial or non-mercurial, altogether satisfactory? Was it so satisfactory that we could afford to ignore other means when they were offered to us? With respect to mercury, he believed it exercised a remarkable influence over the disease. Properly used it would cure the great majority of cases, and properly persevered in would prevent relapses in a large proportion; but it was impossible to say that relapses would not take place, and that in some cases, in spite of it, the patients might not go on from bad to worse, and suffer from all the well-known later consequences of the disease. By the non-mercurial treatment, he believed the progress of the patients would be infinitely more tedious, but not ultimately more satisfactory. If syphilisation would do what its advocates professed it would, we should have a remedy which, though undoubtedly severe in its operation, would do its work without any injurious effect on the system, and we should escape in a very great measure, if not entirely, from all the more serious effects of the disease. Whether it really possessed this curative value was the question to be decided. Sufficient time had not yet elapsed to enable him to express any opinion on this point from his own observation; he was, however, able to say in favour of syphilisation, that hitherto, as far as he had seen, it had effected everything which had been promised for it. The progress of the cases in the Lock Hospital had, in almost every detail, corresponded to the predictions of Professor Boeck respecting them. In several of those who had been longest under treatment, immunity from inoculation with primary syphilitic matter had been arrived at. The reality of this immunity, which had been hotly contested abroad, appeared to him to be unmistakable. It amounted to this, that though fresh syphilitic matter would produce by inoculation a more or less perfect pustule, that pustule would not afford matter capable of successful re-inoculation. Ricord himself admitted that it was not a sufficient test of successful inoculation that a pustule should be produced; any irritant might do as much; it was necessary that the matter of the pustule should be poisonous in its character and capable of reproducing its like. The question of immunity, however, though of great scientific interest, was quite subordinate to the main issue, respecting the curative powers of syphilisation. On this all-important

part of the inquiry he (Mr. Lane) still maintained a neutral position. The lapse of time and continued patient observation could alone lead to trustworthy conclusions. It was a practical question, in the settlement of which epigram and satire would avail but little.

Dr. C. DRYSDALE thought that Mr. de Méric's remarks were too *a priori* in their character. For his own part, before conversing with the learned Christiania professor, and witnessing his Lock Hospital practice, he had, like Mr. de Méric and others, thought that syphilisation was only one of the whims into which enthusiasm will sometimes drive great men. But in the Lock Hospital he had seen remarkable phenomena resulting from inoculations made on persons suffering from secondary syphilis. In the first place, it was an undoubted fact that in almost every case the inoculations began to fail, to become ulcers after ten or fifteen generations; and, again, in two cases of old and severe tertiary syphilis, which had been inoculated by Dr. Boeck, there had been no result until the inoculations had been repeated perhaps a dozen times, with fresh matter each time, and then—but not till then—they began to take, and ulcers arose. Such facts were most curious, and contradicted Mr. de Méric's opinion that a person with ordinary secondary disease being saturated with the virus, Boeck's plan was to saturate the system with the poison, in order that the disease might, like scarlet fever, &c., run through its phases more rapidly, and finally quit the system altogether, and without any chance of relapse. For his own part, after seeing this practice and Ricord's plan, he must say that he would infinitely rather submit to be inoculated twice a week for the cure of syphilis to undergoing a long, perhaps a six months' course of slow poisoning by mercury, even under the auspices of such eminent mercurialists as Messrs. Ricord, de Méric, or Acton. A little pain was not to be compared, in his humble opinion, with the terrible effects he had so often witnessed from that detestable mode of treatment—mercury. At the same time he would say that in almost every case of syphilis he had himself treated, or seen treated, without mercury, and by sound principles of good rational therapeutics, he had not seen any necessity for resorting to syphilisation. Patients in almost every case did admirably with care, good diet, external appliances when required, and vapour baths for the eruptions. It was only in those extremely rare cases, when the disease is from nearly the outset of a rupial character, that he had much desire to see syphilisation tried. Were such a case to come under his notice soon, he thought he would recommend syphilisation to be tried. It could, at least, do no great harm; whilst mercury made such cases nothing short of fearful calamities. He congratulated Mr. de Méric on the way he had spoken of the non-mercurial treatment of syphilis, since he had confessed that it was a very good method of treating the disease, and also that he was at that moment treating indurated sores without the mineral. From the rapid progress recently made by Mr. de Méric, Mr. J. Lane, and other eminent mercurialists, towards abandoning their *old love*, mercury, he fondly hoped to see both of them, and also the majority of the profession, soon converts to the sound doctrines of Fricke, Syme, John Thompson, Hughes Bennett, and the illustrious band of anti-mercurialists. Then at last should we get rid of the great opprobrium of modern medicine, and be able to frame a rational practice of the great healing art. The day was, he was convinced, fast approaching when mercury, as an internal remedy for any disease, would be looked on as a *thing of the past*; but syphilisation was perhaps a great discovery and an important therapeutic agent. At any rate, it was a way of kicking out mercury.

Dr. CLEVELAND had hoped that Mr. de Méric would have brought forward some facts this evening to oppose to the practice of syphilisation. As to the arguments he had used, he protested against them. To say that a mode of treatment was disgusting and immoral was not saying anything to the purpose. What he wanted to have heard

was some reasons derived from observation, not from appeals to prejudices.

Mr. GASCOYEN, without wishing to be included in the ranks of the syphilisators, and, for the present, withholding any opinion as to the merits of syphilisation as a curative treatment, yet thought it was a practice which ought to be tested by us in consequence of the very high evidence in its favour adduced by its advocates, and more especially by Dr. Boeck, whose statements we are bound to receive until they are disproved, and which our personal knowledge of the Professor further compels us all, and even Mr. de Méric, to accept. Dr. Boeck's statistics show that syphilisation possesses a great superiority over all other therapeutical measures in the permanency of its cure, and such being the case it was our duty to the profession and to the public to make trial of it, and more particularly so when we were offered the advantages of the Professor's superintendence and experience. Although much prejudiced against the practice before seeing it, I must now admit that the process, though by no means a pleasant one, is not nearly so painful or objectionable as I had expected; and I am quite sure that, if we can confidently promise our patients a lasting cure, so that they shall never be troubled again with an attack of their constitutional disease, numbers will willingly give up the requisite time and cheerfully submit to the inconveniences of this method of treatment. Mr. de Méric has alluded to a very brief paper on this subject by Mr. Holmes Coote, in a recent number of the *Lancet*, as substantiating his own objections to the practice; but I do not think that much support, whether *pro* or *con.*, can be derived from that communication based upon the observations of only three incomplete cases. The very interesting paper we have just heard seems to me somewhat inconsequent, since the truth of Professor Boeck's statements is admitted by the author; for whilst urging us to adopt the method of treatment which offers the best results, he condemns *in toto* that by syphilisation, which, according to the abovementioned tables, is most successful in preventing relapses. The cases now in the Lock Hospital prove that attacks of constitutional syphilis will get well either in consequence of, or in spite of, syphilisation; but this can be claimed for various other modes of treatment. The advantage which this method is said to possess over all others consists in its power of effecting a permanent cure; but this time alone can prove, and with our present knowledge of syphilisation, we are not yet in a position to give a definitive opinion as to its value, or the reverse.

Mr. DE MERIC, in reply, said it was quite evident to him that anything he could say against syphilisation would not avail at present, since every speaker at the Medical Society and this evening seemed in favour of the practice. He confessed to being a partisan against the treatment, and as it was pretty clear, from what was going on in the medical profession, that some kind of revolution was impending, he was endeavouring to act the part of a "drag," to prevent the vehicle running down the hill too rapidly. When he found proofs of the value of syphilisation he would give in, but in the meantime he thought it a good thing to oppose it as far as possible, in order to make the other side prove its tenets. With regard to what his friend, the honorary secretary (Dr. Drysdale), had said of his seeming tendency towards the non-mercurial treatment of syphilis, he merely used the arguments of the non-mercurialists to combat the syphilisers, he agreed with them.

UNIVERSITY OF DUBLIN.—At the spring commencement held in the Examination Hall of Trinity College on Shrove Tuesday, the 18th inst., the following degrees and licenses in Medicine and Surgery were conferred:—*Baccalauræi in Medicinâ*.—Gulielmus Morton Harman, Jacobus Thompson, Gulielmus Robertus Mac Dermott, Thomas E. Little, Alexander Leney, Michael Shanley, Christophorus Armstrong, Ricardus Edgeworth. Samuel B. Gamble. *Magistri in Chirurgiâ*.—Samuel B. Gamble, Jacobus McCutchan, Edwardus Kough. *Licentiati in Chirurgiâ*.—Wellington Gray, Ricardus Murray Vesey.

Foreign Medical Literature.

REMARKABLE CASE OF GASTRIC TUMOUR.

THE following case, which has been reported in the *Norsk Magazin for Lægevidenskaben* (xix. Bind, 2 Hefte), by Tide-
mand, Physician to the Prison at Christiania, appears to
possess sufficient interest to warrant me in presenting a
translation of it to the readers of THE MEDICAL PRESS AND
CIRCULAR.—Yours, &c. H. MINCHIN, M.B.

Hans Jørgen Hansen, an inmate of the prison at Chris-
tiania, nearly 28 years of age, a working glazier, who had
undergone a previous imprisonment of eight months in
1860-61, was condemned, on the 10th February, 1864, to
be again imprisoned for a term of two years and eight
months. Of a sound constitution, he had always enjoyed
good health, and at the time of his committal had no ail-
ment to complain of. His employment in prison during
the last five months of his life consisted in ornamenting
little caskets and such like with compressed plaster-figures,
and covering the whole afterwards with thick shellac
varnish. In the beginning of July of the same year he
began to experience a sense of weight and oppression in
the cardia, accompanied with a kind of spasmodic inter-
mitting pain through both hypochondria; also impairment
of appetite, with pyrosis, and occasional nausea. In the
latter part of July a hard bulky tumour could be felt in
the pit of the stomach, extending from the left side of this
region to about the median line, as well as we could ascer-
tain. The patient meantime continued quite able to per-
form his work, and also to eat his food without any
positive impediment. Vomiting occurred occasionally,
and he continued to suffer from the pains as above
stated, which, however, were not very violent in character;
and although he became by degrees somewhat paler, he
did not appear to undergo an appreciable loss of flesh.
On the 18th October he was obliged to go to bed, as he
was unable to remain upright without feeling an over-
coming sensation of faintness and vertigo with an incli-
nation to vomit. His appetite declined, the quantity he
was able to consume at this time being about one-half the
diet allowed by the prison diet-regulations for the sick.
After meals he invariably felt an oppression in the epigas-
trium, as if he could not rightly get the food down. On a
careful examination of the tumour, an operation which was
always attended with pain, we found that in transverse ex-
tent it occupied the space from the eighth and ninth
costal cartilages of the left side to about the correspond-
ing part at the right, while from above downwards it extended
from half an inch below the point of the ensiform cartilage
to about half an inch above the umbilicus. The left ex-
tremity of the tumour was concealed beneath costal car-
tilages, but its complete extent in this direction could not
be determined, while the right end appeared somewhat
capable of being defined just beneath the borders of the
cartilages, at about that of the eighth rib. The inferior free
edge of the tumour was rounded, smooth, of considerable
thickness, could not be undermined by the fingers, and ap-
peared to extend deeply into the cavity of the abdomen.
Percussion elicited a dull sound, which, towards the left
side, extended a little beyond a perpendicular line drawn
downwards from the nipple; but towards the right the dull
sound ceased at that place where the right limit of the
tumour was felt, and there suddenly gave place to a clear
or intestinal sound. The tumour felt as hard as
wood; it yielded to the pulsations of the aorta, but we
could not discern that it was otherwise moveable. To
meet the several indications of treatment which presented
themselves in this case, calmative measures were employed,
internally and externally; also local abstractions of blood,
and derivants. The vomitings, which took place from
time to time, contained nothing unusual; they were rather
copious, and consisted in general of slimy bitter fluid,
mingled with some remains of food.

On the 30th October he felt quite well throughout the
whole day, and during a portion of the day even better
than usual; the nausea was less urgent, and only once a
slight ineffectual effort at vomiting occurred. At 9 p.m.
he was, without any assignable cause, suddenly seized with
a violent pain in the epigastrium, of a powerfully constricting
character, which passed directly backwards toward the
spine, and also laterally in the direction of both hypochon-
dria, but was most severe and persistent in the left side,
whence it extended through the breast to the shoulder and
arm; the right shoulder and arm suffered also, but in a
slighter degree. The pains, which at the commencement
made the patient cry out, were particularly urgent during
the respiratory and other movements of the body, which
induced him to lie very still and employ the very slightest
possible efforts at breathing. There was some degree of
tenderness on pressure, gradually extending itself over the
whole abdomen; muscular walls rigid; no distension.
These pains were not accompanied with nausea at first,
but after a couple of hours he had slight vomiting; the
ejected matter consisting, as before, of sour fluid with
some food intermixed. Pulse small, not frequent; face
and extremities cold. The treatment consisted of vene-
section, and the application of leeches followed by a large
poultice, while boric acid and laudanum were adminis-
tered internally. The violence of the pain soon abated;
and on the 2nd November the report states that the
uneasiness had very nearly disappeared; no nausea or
vomiting during the previous twenty-four hours; a thin
scanty evacuation from the bowels on last evening;
pulse 92. On examining the abnormal tumour in the
epigastrium, it was found to be not so tender as pre-
viously, while its upper edge had moved downwards a full
half inch, the superior border of the swelling being at
this time situated more than an inch below the point of
the xiphoid cartilage, and in the same way the inferior
boundary had become depressed to the level of the umbi-
licus. On this day it was found also that the coverings were
separated from the subjacent tumour, by an intermediate
collection of air mixed with a little fluid, to about half an
inch in depth—a phenomenon which had not been pre-
viously observed. On the following day this collection of
air was hardly to be perceived, and it soon disappeared
altogether.

Matters continued now to go on favourably until the
10th November, when, at about nine p.m., a violent rigor
came on; this lasted for a whole hour, and was succeeded
by great heat and afterwards perspiration, with headache
and a feeling of soreness and numbness over the entire
body. Next morning at four o'clock he was seized with
nausea and some vomiting, but the nature of the matters
ejected could not well be discerned in the tub of water
into which he had vomited. Soon afterwards severe pain
was felt in the epigastrium, of the same character as that
described in the former attack, but not quite so violent.
This pain continued with unaltered activity, and extended
gradually in the course of the day over the entire abdomen.
In the afternoon his appearance was dull and lethargic;
the skin cold and clammy, especially on the hands and
feet; the face, and even the tongue, cold; occasional
hiccup. On the 12th the same state continued, but in an
aggravated degree; pulse scarcely to be felt. During the
last two days no urine was passed, and on introducing the
catheter on two occasions daily scarcely two spoonfuls of
reddish turbid urine came away. He died on the 12th
at 7.5 in the evening.

At the necropsy, which took place thirty-eight hours after
death, were found signs of inflammation extending over
the whole peritoneal surface, with considerable exudation
of serous and gelatinous fluids, and the tumour which had
been felt during life in the epigastrium was found to be
within the stomach. On account of this peculiarity in
the case, the whole of the alimentary abdominal tract was
removed, ligatures having been previously applied at either
end, and was transmitted to Professor E. Winge, who has
been kind enough to exhibit the preparation to the Medical

Society of Christiania, together with a description thereof, as follows:—"The stomach was dilated to about the size which this organ might attain when moderately distended with air. Its form was natural, with an opening or perforation on the lesser curvature of more than an inch in diameter. This organ was felt to be as hard as bone or wood, and yielded in several places a crepitating feel, which was most remarkable near the fundus at the anterior wall. After it was cut open it was found to enclose a brown mass of a woody hardness, which filled its entire cavity, so that it formed a complete cast of the form of the stomach without adhering to the walls at any part, although everywhere in contact with them. On the outer surface of the mass, where the crepitating sensation was observed, were found several smooth laminæ of the same substance partially adhering to the subjacent mass; and at the place corresponding to the perforation of the stomach, a broad prominence, about half an inch high, terminating in a sharp point. In other respects the surface generally was smooth, but marked with striæ of undulated form, such as a coagulating mass in the process of forming a cast of the lining membrane of the stomach would exhibit. It had no opening, either on the sides or at the parts corresponding to the pylorus and the cardia; it floated in water, although some parts of the mass were specifically heavier than this fluid; it might therefore contain a cavity, or might consist internally of layers with air intervening. It weighed two pounds ten ounces. On subjecting it to chemical examination it appeared to consist of an organic substance, easily soluble in warm alcohol, burning with flame and a distinct odour of shellac, and leaving behind only a small quantity of a light ferruginous ash, probably from the admixture of gastric fluids (blood and mucus). Doubtless, then, it consisted of shellac or of a resinous matter resembling it. The stomach exhibited, in addition to the perforation above mentioned, a superficial erosion on the anterior wall. On the serous surface, as on that covering the other portions of the abdominal organs, were found traces of the peritonitis, which had been the immediate cause of death, occasioned by the sharp prominence which had eroded a hole in the wall of the stomach. This surprising case, which is perhaps unique in the annals of medicine, derives an easy explanation from the information afforded by the circumstances which attended the patient. His employment in the prison was in fact to varnish toys, &c., and for this purpose he made use of a thick shellac varnish; of this he had been doubtless for a long time consuming considerable quantities, probably as a substitute for other inebriating liquors; the shellac had settled as a deposit in the stomach, while the spirit was absorbed, and thus by degrees this singular concretion became formed. It is particularly worthy of remark, that the process of digestion appears to have gone on without much difficulty, as is shown by the patient's good condition; also the fact that the symptoms, on the whole, had been so very slight previously to the supervention of the fatal perforation."

With respect to the general conduct of the deceased while in confinement, the prison director certifies that it was always irreproachable; he was a diligent and orderly prisoner, who worked with zeal and intelligence, and always appeared to be careful and prudent with anything that he had in hand. Before his imprisonment he had been addicted to drink, but while in the prison no one had ever observed that he was tipsy at any time, or even had smelled of spirits. If this latter had been remarked, however, it could easily have been assumed that he was continually inhaling the vapour of the varnish that he employed. The attendant who had the immediate care and inspection of his work had remarked truly enough that there was a very large quantity of shellac varnish expended, but with regard to this the prisoner declared that, as the principal things to which the varnish was applied were plaster ornaments and wood, these porous substances imbibed so much of the material that the apparently excessive expenditure thereof could be explained in that way; and, as this kind of work had never been previously per-

formed in the prison, no one was able from experience to estimate the probable waste of varnish which had thus occurred. The varnish which had been employed contained about five and a half ounces shellac to one quart of spirit (Norwegian sp. of 14°), and was of the consistence of ordinary syrup. The lump found in the stomach weighed, as already stated, two pounds ten ounces, or forty-two ounces, of which only an insignificant portion by weight consisted of other substances than shellac. Assuming it probable that the concretion then contained forty ounces, which, according to the proportion of resin to spirit in the varnish above given—five and a half ounces to the quart—may be about equivalent to the contents of seven and a quarter quarts of varnish. This, then, is the quantity which the deceased had swallowed during the five months, or 150 days, he had this material in his hands; and in order to drink these seven and a quarter quarts, which, estimated by the volume of a spoonful, would contain about 464, he must have taken somewhat more than three spoonfuls daily; of which portion, insignificant when considered with reference to the quantity of work which he delivered, it was hardly possible to keep an account.

ON THE PATHOGENY OF CYSTOID KIDNEYS.

By W. KOSTER.

Translated from the *Nederlandsch Archief voor Genees- en Natuurkunde*, 1e Deel, 2e Aflevering, Utrecht, 1864, for THE MEDICAL PRESS AND CIRCULAR.

By WILLIAM DANIEL MOORE, M.D. Dub., M.R.I.A.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS, OF THE NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

THE circumstances under which cysts become formed in the kidneys are very various. In general, however, the occurrence of cysts may with great probability be referred to changes in the tubuli uriniferi.

Every gland which contains closed vesicles or tubes has in its structure a tendency to the formation of cysts. The thyroid gland, the ovary, and the kidney may in this respect be taken as types.

In a tubular gland, such as the kidney, obstruction to the efflux of the secreted fluids will produce dilatation of the tubes. If other circumstances be favourable, the foundation of the formation of cysts is laid.

This view is so simple, and so much in accordance with the process of development of cysts in other places (excretory ducts of larger glands: salivary, mammary glands, &c.), that we are naturally led to explain the occurrence of renal cysts in general in this way. Anatomical investigation has already brought to light many facts in confirmation of this opinion.

But if we study the pathogeny of renal cysts more closely, a number of questions suggest themselves. Thus the consideration immediately arises, and it is applicable to all other cysts—can they be developed *ab initio*, or do they spring always from a normally existing cavity with a proper wall?

Moreover, we meet with renal cysts in very different alterations of tissue of the kidneys. Sometimes they have no remarkable influence on the function of the organ; they are discovered casually in the course of post-mortem examinations. In other cases the development of cysts is evidently the morbid process, which must be looked upon as the proximate cause of the deranged vital phenomena and of death. Sometimes we can find no distinct predisposing cause of the occurrence of the cysts; sometimes the primary morbid process is distinctly demonstrable. At one time many and large cysts co-exist with slight alterations of tissue; at another a kidney exhibits no cysts in the midst of very important degenerations.

But, as the title of my essay indicates, my object is not

to treat of the whole extensive range of the pathogeny of renal cysts. I would only contribute something to our knowledge of the occurrence of a definite form in which renal cysts appear, while some of the questions alluded to come now and then incidentally under consideration. To explain the nature of my subject, a short review of the forms in which renal cysts occur is necessary.

To find very small and larger cysts to the number of two, three, or more in a kidney, which otherwise presents no morbid changes, is very usual in the course of post-mortem examinations. Rarely do we succeed in demonstrating the mode of origin of these cysts in a given case; we must deduce this from what investigation has taught in other instances.

Moreover, we meet with small cysts in atrophic kidneys, whether the atrophy is to be considered as physiological, proceeding from the changes of age, or whether it constitutes the last period of other morbid alterations of tissue (often comprised under the general name of Bright's kidney). The kidneys may then be studded with small microscopic cysts, but may also contain some larger ones.* Especially in cysts, arising under these circumstances, colloid occurs in different forms.

The fresh formation of cysts, in which the singular products occur, which are known under the name of Dermoid, is but very rarely met with in the kidneys.†

In these forms cysts, &c., appear. I shall not speak more fully of their mode of origin, their consecutive changes, and their contents.‡ There is, however, another comparatively rarer mode of development of cysts; that in which the whole kidney is changed into a great quantity of partly coherent, partly wholly closed sacs, filled with serous fluid, which assemblage of cysts may occupy a great space. Here we have to deal with no accidental development of cysts occurring with other processes; the entire kidney is changed into cysts; and the occurrence of the latter is the characteristic of the process.

This typical development of cysts may be distinguished by the name of *cystoid kidney*, or *cystoid degeneration of the kidney*. It forms a characteristic independent morbid process, which may occur in foetal life, as well as in adults, but in the latter it is met with in general in advanced age.

In order to avoid repetition, and to place before the reader a clear sketch of the change of the kidney in question, with the present position of our knowledge on the subject, I shall refer to Förster's accurate description (in his *Handbuch der pathologischen Anatomie*, Th. ii., p. 497), and shall copy a part thereof: "Much more rarely than the isolated cysts, we sometimes meet with such a massive formation of cysts that the whole kidney is destroyed by it: *cystoid degeneration of the kidneys*, the change always affects both sides, being sometimes less extensive on one side than on the other. In the most perfect cases the kidney is considerably enlarged, sometimes to the size of a child's head and more; its surface exhibits small and large cysts closely compressed together, between which not a trace of normal substance is visible. If the kidney be cut through in the usual manner, we see on the surface of section nothing of the normal texture, no remains of a division into pyramids and cortical substance, which placed close together, allow to be seen between them only *débris*, consisting apparently solely of connective tissue and vessels." Further, the composition of such a cystoid kidney of larger and smaller, sometimes microscopic vesicles, is described, while the discovery of dilated tubuli uriniferi in the small portion of interstitial substance

which still remains, indicates very distinctly the origin of the cysts. But whether in all cases, Förster continues, "of cystoid degeneration, particularly in adults, the cysts are formed in this manner, is still uncertain; I have in no case been able to refer their origin to the connective tissue cells of the renal stroma. Beckmann thinks he has observed such a case, but his results are capable also of another explanation. The renal calyces are for the most part obliterated, or are still only just indicated. In less exquisite cases the number and size of the cysts are less, and between them more normal renal tissue is preserved; the enlargement of the kidneys is less considerable. This degeneration occurs at all ages, even in the foetus."

In this description of Förster's the leading points of what is known respecting the pathogeny of cystoid kidneys is comprised. *Probable development of the cysts from altered tubuli uriniferi or Malpighian corpuscles, in the cortical substance of the kidneys; absence of the Malpighian pyramids, and of the renal papillae in the fully-developed cystoid kidneys; occurrence of the degeneration at any age, even in foetal life*—constitute the few data which are available for an account of the origin of the cystoid change. Of the alterations of tissue in places where no cysts as yet exist, Förster does not speak—*between them sometimes more normal tissue is preserved*. To his statement also, *that the disease occurs at every period of life*, we must again revert.

The numerous and admirable investigations of O. Beckmann* have very much extended our knowledge of the origin and further changes of renal cysts. But in consequence of the nature of his work, he has not treated of the development of the *cystoid kidney* as a distinct process, but has spoken of the formation of the contents and walls of cysts in general, the metamorphoses of their contents, their origin from newly-formed or already existing morbid elements, &c. The application of his results to the metamorphoses of the distinct cysts in cystoid degeneration is easy; but the consideration of the latter as a *process*, the tracing of the nature of the degeneration, and of the proper pathogenic element, are wanting.

Under these circumstances it appeared to me not unimportant to communicate the results of my investigation respecting two kidneys, which were in an early stage of cystoid degeneration. Probably it is to be attributed to the want of a special pathogenetic consideration of the cystoid degeneration of the kidneys, that we rarely meet with other than fully-developed examples of this disease, such as those represented by Rayer† and Lebert,‡ which quite agree with a preparation in the anatomical museum in Utrecht. I shall first give a short case, with a description of the renal changes found after death, and shall then proceed to make some remarks on other cases in connexion with mine, concluding with an attempt at a pathogenetic explanation of the same.

a.—History and Anatomical Examination of a Case of Cystoid Degeneration of the Kidneys.

On the 12th of January, 1864, N. W., a married woman, aged 51, was admitted into the Hospital of Utrecht. From the notes kindly given me by Dr. Inans, the following appears:—The patient had previously in general enjoyed good health, but eight or ten days before her admission she had, according to her statement, "a nervous attack," after which she continued to feel pain throughout her whole body, and was rigid in her movements. On her admission consciousness was unimpaired; she complained of universal pains, had a gastric loaded tongue, and a quick pulse. The following day she suffered from nausea and diarrhoea. On the 14th she complained of difficulty of breathing, and on physical examination some infiltration of the lower lobe of the left lung was discovered. In addition, slight convulsive spasms of the muscles were observed, especially of those of the face.

* Conf. on this subject, anatomico-pathological works, and the essay of Gildemeester: On Morbus Brightii and Albuminuria in the Nederl. Tijdschr. tot bevord. der geneesk. 1st Jaarg., p. 379.

† Paget, *Chirurgical Pathology*, II., p. 84.

‡ The literature of renal cysts is to be found in any manual of pathology. Among the later essays those of O. Beckmann, in Virchow's *Archiv*, Bd. ix., p. 221, may be named.

* Virchow's *Archiv*, Band xi., pp. 50 and 121, and elsewhere.

† *Maladies des reins*, Atlas, pl. xxvi.

‡ *Anatomie pathologique*, t. ii., pl. 138.

At night she was restless and began to rave. On the 15th the convulsive movements increased, without, however, the occurrence of decided fits; in the evening the woman fell into a semicomatose state. On the 16th she was very much collapsed, comatose, cyanotic, had cold extremities and an exceedingly quick pulse. Under these symptoms she died at two o'clock in the morning, without a diagnosis having been made. The only thing which might have led to the otherwise wholly undefined idea of renal disease, was the very small quantity and extremely dark colour of the urine voided, in which, however, no other peculiarities were discovered.

The *post-mortem* was performed on the following day.

The membranes of the *brain* were highly congested, the cerebral substance also on section exhibited many points of blood. The upper part of the medulla spinalis, which could be examined, exhibited no morbid changes.

The *thorax* was badly developed, flat and slightly compressed in the middle. The thoracic organs occupied their usual situations. The heart and the right lung were normal. The left lung contained much fluid—in the upper lobe mixed with air and yellowish, in the lower lobe thicker and of a brownish-red colour. Moreover, the lower lobe contained air only in the air-tubes, while the proper pulmonary tissue was jelly-like, and was of a reddish-brown colour.

In the *abdomen* a peculiar spot on the upper surface of the right lobe of the liver, close to the suspensory ligament, at once caught the eye. There were there numerous little cysts, of the size of grains of millet, and of hemp-seed, the two or three largest being as large as a pea. All these sacs contained a clear light-yellow albuminous serum. The surface of the liver, on which these vesicles were situated, or in which they properly lay, was of a whitish colour, and was formed of a layer of connective tissue two or three millimetres (about one-tenth of an inch) in thickness, which passed, without defined boundaries, into the hepatic substance. The liver had quite the appearance of an incipient cirrhotic liver. Beneath the spot with cysts just mentioned, and where the tissue was again of a brown colour, an extraordinary quantity of connective tissue was found, while the hepatic cells were atrophied: the peculiar lobular arrangement of the latter had disappeared; they lay irregularly scattered.

On the surface of both ovaries, especially on that of the right, numerous small cysts projected. The number of these amounted on the right side to about sixteen. These cysts, of the size of hemp-seed and of peas, all contained a serous fluid.

Of the other abdominal viscera, with the exception of the kidneys, there is nothing to remark. The kidneys occupied their normal situation, and could easily be removed. The renal pelvis, the ureters and bladder exhibited no trace of morbid change. The extraordinary quantity of cysts, with which both kidneys were uniformly covered over their whole surface, immediately caught the eye.

The kidneys were remarkably larger than usual. On section it appeared that neither were the cysts wanting internally. Nevertheless, a very large portion of the renal tissue still remained. This was in general of a dark-red colour, and was loaded with blood and serum. The cortical substance contained very many cysts, and was thereby enlarged; here and there the colour was more marbled. On the surface of section of the Malpighian pyramids only a few very small cysts were seen. Most of the cysts projected, as I have already said, on the surface and along the convex margin of the kidney. They were of very different sizes, varying from that of a hazel nut to that of a pea and less. The wall of the cysts was formed in great part by the tunica albuginea. The largest had, moreover, a distinct independent fibrous wall, with an epithelial layer. The smaller, on the contrary, were bounded only by a smooth extremely thin layer, which could scarcely be looked upon as an independent membrane.

Most of the cysts, particularly the largest, were filled with a clear, serous, albuminous fluid. The smaller ones, on the contrary, contained a light-brown or dark-coloured viscid fluid. In the clear serous fluid microscopic examination exhibited no morphic constituents worth mentioning. In the light or dark-brown viscid fluid, on the other hand, all kinds of forms were visible, and indeed the same in both; only the dark, nearly black mass, contained more irregular and very dark-coloured granules. The morphic constituents were, in great part, peculiar, brownish bodies, the contents of which converging, as it were in rays, from the circumference to the centre of the body, were divided into conical portions. Each of these portions contained a small dark point. The contents were otherwise slightly granular. Their diameter was from 1-50th to 1-100th mm. Other cells, of round or oval shape, with a very thin wall, contained two, three, or four smaller cells. The enclosed cells quite agreed in size and appearance with the innumerable smaller cells which floated around in the field of vision. Their contents were slightly granular or clear; only in a few was a small nucleus seen. A third peculiar cell form was met with; these were mere oval cells, whose wall consisted of concentric layers, somewhat smaller than the large bodies divided into conical segments. Between these forms, moreover, irregular light-brownish granules and larger masses were met with. It was remarkable that the larger irregular granules, and some of the smaller, became of a very distinct violet colour on the addition of Schulze's reagent. The proper morphic constituents were not altered, while the change of some of the concentric cells was doubtful.*

The appearance of the Malpighian pyramids was very peculiar. Their size was rather diminished than enlarged. Their colour was less red than that of the cortical substance of the kidney; it was more brown, like that of healthy renal tissue. With this brown colour numerous white streaks running from the base to the top of the pyramids strongly contrasted. At the base of the pyramids the streaks were more diffuse, yellowish; towards the papillæ they became more distinct, white, and with some of the papillæ they even wholly coalesced. These papillæ were at the same time small, firm, as it were atrophic. (See Plate II., Fig. 1.) Only three or four of the papillæ in the left kidney had retained more brown-coloured tissue, and were merely streaked with white.

The nature of the changes in the pyramids and papillæ was rendered evident by microscopical and microchemical investigation of longitudinal and transverse sections. Fig. 2 gives a representation of a longitudinal section of a

* It was at first my intention to have treated still more fully of the contents of the cysts, and to have illustrated the forms described with drawings; but on referring, for the purposes of my essay, to the investigations of O. Beckmann, it appeared to me that he had seen and represented all the above-mentioned forms. Virchow, too, speaks in different places of the peculiar concentric bodies, and of those divided into segments, without giving an explanation of them. The amyloid reaction of some constituents of the cystic fluid I have not, so far as I remember, found recorded. To avoid repetition, I shall therefore confine myself to what I have stated respecting the contents of the cysts, and treat more in detail, and illustrate by drawings, only the peculiarities in the anatomical alterations of the kidneys, which are more immediately connected with my subject. If I might in passing venture a conjecture as to the signification of the peculiar morphic constituents, I should think that the bodies divided into segments are altered, but still very strongly coherent epithelial cells of the tubuli uriniferi. Their appearance, in fact, reminds one of a transverse section of a uriniferous tubule in the cortical substance. Some of the cells degenerate into the amorphous masses, and undergo chemical changes, whereby, among others, in many the amyloid reaction arises. Others continue to live under modified circumstances and produce the parent with daughter cells, met with in the contents of the cysts, while from them the many small cells might easily be derived. Only the origin of the cells with concentric layers is more difficult of explanation.

papilla strongly streaked with white, and highly atrophied at the extremity. *It appears that the tubuli uriniferi at the end of the papilla are completely closed; properly speaking, on the whole they no longer exist.* We find a mass of connective tissue in which dark granules lie irregularly scattered, and only faint outlines of tubuli uriniferi, also filled with dark granules, remain. On a transverse section, too, no trace of the openings of the tubuli is met with, at least not in the situations of the microscopically visible white streaks. Between these were again spots, with the well-known cribriform appearance of a transversely cut renal papilla; in some tubuli there was still indistinct epithelium (Fig. 3.)

If we view the transverse section higher up, it will appear that the dark granular matter is contained chiefly in the tubuli uriniferi, especially in the loop-like tubuli of Henle, less in the straight ones. The tubuli are completely stopped by it. Between them the connective tissue is much increased in bulk, has here and there, as it were, pushed away the tubuli, and contains irregularly scattered dark granules. These dark granules (which were brilliantly white to incident light) were not altered by the addition of potash; the intervening matter became more transparent on the addition of weak acetic acid. Dilute hydrochloric acid immediately caused a brisk development of bubbles under the microscope, and made the dark granules for the most part to disappear. I therefore had no doubt that calcareous infarction and increase of connective tissue existed, with consequent contraction and atrophy of the renal papilla. On longitudinal sections more towards the base of the pyramids, likewise, unmistakable increase of the connective tissue between the tubuli uriniferi was observed. The calcareous infarction extended pretty highly into some of the tubuli, especially the loop-shaped ones, but without obstructing them as completely as in the renal papilla. Here and there highly dilated tubules were met with, evidently the commencements of cysts. (To be continued.)

Reviews.

PHOTOGRAPHS (COLOURED FROM LIFE) OF THE DISEASES OF THE SKIN. Second Series. By ALEX. BALMANSO SQUIRE, M.B.Lond. London: Churchill.

THE present number of this series contains a photograph of the skin eruption of the cattle plague, and the part represented is the teat and part of the udder of a cow at the seventh day of the disease. Near the roots of the teat there are exhibited four well-marked crusts of about the size and thickness of a split pea, of a brown colour, and presenting the berry-like crusts produced by small-pox in the human subject. Mr. Squire states that in other cows which he examined the eruption presented the same characters as those shown in the present photograph. The representation of this disease will be very interesting, and Mr. Squire has done well to produce it at once, because the hypothesis of the identity or close resemblance between cattle plague and human small-pox is already becoming almost a thing of the past, although the points of resemblance are in many respects very striking. The photograph, like all the rest of the series, is very well executed.

THE POPULAR SCIENCE REVIEW. Edited by HENRY LAWSON, M.D. No. 18. January, 1866. London: Hardwicke.

HARDWICKE'S SCIENCE GOSSIP. No. I. Vol. II. THE first of these periodicals is published quarterly, and the second monthly. Both are of a popular character, but the *Review*, as may be supposed, is of a more solid and substantial character than the *Science Gossip*. The *Review* consists of original articles, written by eminent naturalists, and illustrated by numerous well-executed engravings, some of them coloured; or reviews of the principal works on natural his-

tory emanating from the modern press; and of a Scientific Summary, recording the progress of physical science in all its branches. The *Science Gossip*, which is brought out with great profusion of illustration, and is published at a very cheap rate, consists of short articles relating to different points in natural history, not arranged in any consecutive order, but taken apparently as opportunity presents itself. Still a great amount of information is thus conveyed to the reader, and as the science is all of a sound character, the person who takes up the pages for the mere purpose of a little desultory amusement may find that he has unconsciously acquired many sterling truths in natural science. The *Review* and the *Science Gossip* are well worthy of the support which, we believe, has been extended very liberally to both.

THE HOUSEHOLD: a Magazine of Domestic Economy and Home Enjoyment. No. I. 1866. London: Groombridge.

THIS is a new magazine, devoted, as its title implies, to matters connected with the cares and duties and enjoyments of home. Thus we find among the subjects discussed such matters as the ordering and arrangement of dinner parties, medical memoranda for the household, cheap cookery for dear times, the cultivation of tea, and many other such topics, which are all treated with considerable ability, and in a popular and agreeable style.

RATIONALISM AND EMPIRICISM IN MEDICINE.

EVERY honourable Practitioner of Medicine or Surgery must often ask himself the question how far his treatment of accidents or diseases is founded upon scientific doctrines, and how far it is guided by experience or routine. Important as this question must have been to thoughtful physicians in all ages, it is still more important in the present age, when ardent minds, both among the Profession and among the general public, are exerting themselves to solve the great problems involved in the mysteries of life and death, of health and disease, with a view of determining the best and surest methods of applying remedies for the maladies incident to human beings. It is natural, too, that the mind, surveying the magnificent but awful spectacle presented by the creation around it, should attempt to fathom the design everywhere apparent, but not always definitely understood, and should moreover, when wondering at the results already achieved by human reason, aspire to know still more of causes and effects, as they are linked together in the great scheme of nature.

The truths developed by the sagacity of mankind in different ages and countries are so startling by their novelty, and so brilliant in their generalisations, that the conclusion is not unreasonably suggested that diseases and their treatment ought to be amenable to the same laws of induction as any other physical conditions in the universe around us. The laws of attraction, for

instance, explain satisfactorily and universally many of the most obvious phenomena in nature, from the fall of a stone to the earth up to the flux and reflux of the tides and the motions of the heavenly spheres, and why, it may be asked, has some similar law not yet been established to account for the phenomena of disease? or why has not some constant ratio been yet discovered between the morbid states of the human body and the agencies which restore health? Unsatisfactory as the answer may seem, it is nevertheless true that theories of diseases and their treatment have all been condemned, and justly condemned, as inadequate to satisfy the demands of intelligent inquiry, while a rational empiricism, if such a term can be allowed, appears to form the only basis of sound and successful practice.

It may, however, be asked what is meant by rationalism and empiricism in Medicine, and whether these two principles are antagonistic to, or may be made harmonious with, one another. Now, as an instance of rationalism, we may cite the well-known homœopathic dogma, *similia similibus curantur*, which is the shibboleth of the disciples of Hahnemann, and which posed to be in opposition to another dogma (which, however, has no existence) ridiculously termed allopathy. The dogma of the homœopaths has the great merits of simplicity and intelligibility, for there is nothing absurd in the idea that one disease may cure another, just as two waves of sound coming in opposite directions may produce silence, or two waves of light coming in opposite directions may produce darkness, or two moving forces coming in opposite directions may produce rest. The only objection to the doctrine of Hahnemann is that *it is not true*, or at least that it is true only in so small a number of cases as to forbid us to elevate it to the rank of a law of nature. There is no exception whatever to the law that darkness may ensue from the meeting of two opposing waves of light, that silence may result from the meeting of two opposing waves of sound, or that rest may result from the meeting of two moving forces, but the exceptions to the law that one disease cures another are so overwhelmingly numerous as to annihilate the law altogether. So, again, we must admit that the doctrine or the dogma, once entertained and acted upon, and often verbally expressed, that blood-letting was the remedy for inflammation, is equally fallacious, because inflammation may be and is cured without bleeding at all, and, what is more, will often be cured better without the supposed remedy than with its aid.

It is needless to run through all the theories of Medicine which have been invented from the time of Hippocrates and Erasistratus down to that of Brown and Broussais, for they are all alike unsatisfactory, and we are at last driven to the conclusion that the only true Rationalism in Medicine is that which derives its origin from a careful examination of healthy and diseased structures. This method of viewing the matter is very well put by Celsus in his first Book of Medicine, when,

after reviewing the theories proposed by the Rationalists of his own and former times, he puts into their mouths the most stringent arguments for the study of anatomy. How, they say, can those who are ignorant of the structure of the human body be able to apply remedies for its diseases, and how can a person know the treatment of an internal malady when he does not understand the cause of the symptoms he observes? The knowledge of anatomy and physiology is, in fact, the only true rationalistic theory of disease; without this knowledge all systems of Medicine are but groundless fancies, and even with it there is still very much for the most accomplished anatomist and physiologist yet to learn.

In the employment of the word empiricism at the head of this article, it will be at once understood that we do not regard it as synonymous with quackery, but rather in its etymological signification, as indicating the knowledge gained by experience; and in this sense it will be found that the most illustrious practitioners of our Profession are really empirics. For, again, to quote Celsus in his exposition of the empirical doctrines of his time, the best physicians would be the philosophers and the students of abstract knowledge, if Medicine were based solely upon reasoning; but just as a farmer or a pilot obtains his knowledge from practice, so does a physician or a surgeon become skilful in proportion to his acquaintance with the phenomena of disease, and with the results of the treatment he has seen adopted in different places and at different periods.

We therefore come to the conclusion that the best guide to successful practice is a modification of rationalism with empiricism; the first consisting, not in ingenious though probably groundless hypotheses, on the nature of health and disease, but in a careful and conscientious study of healthy and morbid anatomy, of physiology and pathology; and the second consisting in a patient investigation of disease in the living subject, under all conceivable diversities of time and place, and under all varieties of constitution, and all results of treatment. To arrive at any consistent and faultless theory of disease, or any perfect system of therapeutics, appears to be a task beyond our present powers; but the path of laborious investigation, however toilsome, is the true road to successful practice, and the only one which can yet be trodden with safety.

TESTIMONIAL TO DR. J. SEATON REID.

THE medical man's remuneration for his services is not to be measured solely by his fee; he looks for gratitude and appreciation from his patients when his work has been done well and conscientiously, and such reward is the best incentive to his exertions. We observe with pleasure that a handsome address which appears in our journal to-day and a valuable presentation has been made to Dr. J. SEATON REID, of Belfast, by a large number of his friends, including many of his professional brethren, and we heartily congratulate Dr. REID on the cordial feelings which the donors expressed.

THE REPORT ON THE
RANK, PAY, AND POSITION OF ARMY AND
NAVY MEDICAL OFFICERS.

THE Report of the Committee appointed to inquire into the whole question of the Rank, Pay, and Position of Medical Officers of the Army and Navy has been printed.

For the Army the Committee recommend—

1. That at all boards upon which Army Medical Officers may be summoned as members, they should sit and take precedence according to their relative rank, and should preside, if senior in relative rank to the combatant officers, with the exception of courts-martial and courts of inquiry on military offences.

It is, however, suggested, for the consideration of the authorities, whether it is not advisable to establish regulations for referring all necessary questions to Medical Officers for their opinion and report, and to discontinue the system of mixed boards.

2. With the view of preventing misunderstanding as to relative rank at mess:

That invitations sent by the colonel, or officer commanding, in the name of himself and the officers of a regiment, be considered official, and that the senior combatant officer present should always preside; and

That where a second position is formally assigned on such occasions, such position should be determined by relative rank, as defined by the Queen's Regulations and Warrants.

3. That in the Monthly Army List, the names of the Medical Officers of each regiment be inserted above those of the other regimental staff, with a heading of "Medical Officers."

Also, that a general list of all Medical Officers in the army be inserted in the Monthly Army List, and that in

such list the relative rank of each class of Medical Officers with the corresponding rank of combatant officers should be clearly stated; thus:

Inspectors-General of Hospital (ranking with major-generals).

Deputy Inspectors-General of Hospital (ranking with colonels), &c.

And that opposite the name of each officer should be the number of his regiment or the station on which he is serving.

That Medical Officers be replaced in the list of the regimental staff in the classification of officers in the Queen's Regulations; and it is submitted for consideration whether the Medical Department should not be placed immediately after the lists of combatant officers in the Army List.

4. That Medical Officers, ranking with field officers and being allowed forage, should be ordered to provide a charger and to appear mounted on parade.

5. That increase of pay and earlier retirement be granted, as defined in paragraphs Nos. 9, 10, and 11.

9. In view of the proper requirements of the service in this regard, and in order to encourage the coming forward of a larger number of the most eligible class of candidates, and thus to render the competitive examination really worthy of that name, and such as was contemplated upon its establishment, the Committee, from the information before them, and supported by the deliberate opinions of gentlemen of the highest professional attainments and experience connected with the Medical schools of London, who have been examined, consider that, besides the removal of the alleged grievances of Medical Officers above referred to, a certain increase of pay is absolutely called for; and with this view, and after full consideration, they recommend that an increase of pay should be extended to the Medical Officers.

SCALE OF PAY PROPOSED FOR ARMY MEDICAL OFFICERS.

RANK.	Under 5 years' service.		Above 5 years' service.		Above 10 years' service.		Above 15 years' service.		Above 20 years' service.		Above 25 years' service.		Above 30 years' service.	
	Present rate.	Proposed rate.	Present rate.	Proposed rate.	Present rate.	Proposed rate.	Present rate.	Proposed rate.	Present rate.	Proposed rate.	Present rate.	Proposed rate.	Present rate.	Proposed rate.

Surgeons	s. d. 15 0	s. d. 17 6‡	s. d. 18 0	s. d. 20 0	—	—	—	—	—	—
Surgeon-Majors	s. d. 22 0	s. d. 24 0‡	s. d. 25 0	s. d. 27 0	—	—

† Or on promotion.

‡ Provided he passes his examination.

A proposal to increase the pay of the inspectorial ranks was made, but the Committee, being divided in opinion, do not make any recommendation.

10. The Committee also consider that the prospect of optional retirement at an earlier period than at present permitted would prove a further inducement to young Medical men to enter her Majesty's service; they therefore recommend that Army Medical Officers should be permitted to retire after twenty years' service on full pay; but at the same time, with a view to guarding the interests of her Majesty's service, they are of opinion that the rate of half-pay awarded to officers so retiring should not exceed five-tenths of their full pay, and that officers with this service should be permitted to retire on the present

half-pay of their rank, if, after one year on half-pay, they are reported by a Medical Board to be permanently unfit for further service.

11. The Committee further recommend that, as a special reward to officers of long and good service, who, owing to the comparatively small numbers of the inspectorial ranks, have not been promoted to any higher position than that of surgeon-major, such officers, of the rank of surgeon-major, as have served for twenty-five years on full pay should, on being compulsorily retired at fifty-five years of age, receive the half pay of £1 a day, but such officers retiring voluntarily under fifty-five years of age should receive only seven-tenths of their full pay.

For the Navy the Committee recommend—

1. That Staff-Surgeons be placed on a separate list, and considered as a distinct rank, and that promotion to that rank (although twenty years on full pay may not have been completed) should be open to officers for distinguished or special service.

2. That the whole time an Assistant-Surgeon serves on full pay should be allowed to qualify for the rank of Staff-Surgeon, provided he passes his examination for Surgeon before he completes ten years' service.

3. To compensate the Naval Surgeon for loss of time, by his being placed on half-pay, and unable to obtain employment, the Surgeons' and Staff-Surgeons' full pay should increase by periods of four years, instead of five years as at present.

4. That Naval Medical Officers be granted the same allowances at hospitals at home and abroad as the Army Medical Officers, in respect to servants, fuel, furniture, or pecuniary allowances in lieu.

5. That the scale of travelling allowances, extra pay, lodging money, and compensation for losses, be fixed for Naval Medical Officers according to relative rank.

6. With respect to the question of prize money, the Committee, owing to the present principle on which the Prize Proclamation is drawn, are unable to agree upon a special recommendation, but are inclined to the opinion that the share of Medical Officers should, after the officer in command of the ship, be regulated by relative rank.

7. That in regard to cabins, while the requirements of the service render it necessary that the senior executive officer and the staff commander or master should have the

cabins placed most advantageously for their special duties, Medical Officers should after them have cabins more in accordance with their relative rank in the service, and that cabins for all Assistant-Surgeons should be specially ordered, to prevent future difficulties or neglect of the existing Admiralty Order.

8. That a Staff-Surgeon, ranking with commander, be allowed a servant.

9. That a Staff-Surgeon should be appointed to all flag ships bearing the flag of a commander-in-chief on foreign stations, with an allowance of 5s. a day in addition to his established pay.

10. That the periods of retirement by age be fixed for Staff-Surgeon, Surgeon, or Assistant-Surgeon at fifty-five years; Inspector-General and Deputy Inspector-General at sixty-five years; but this regulation should only apply to new appointments.

11. That Naval Medical Officers be considered equally eligible to honorary distinctions as army medical officers.

12. That they should have equal consideration for Greenwich Hospital pensions with other officers of the service.

13. That Assistant-Surgeons, after completing their time for examination for the rank of Surgeon, be granted two months' leave of absence on full pay, on the condition of their resuming their studies at a medical school or hospital.

14. That in order to place Staff-Surgeons on an equality in rank with Surgeons-Major in the army, they should rank with commanders by date of commission.

15. That the pay of the Naval Medical Officers be increased.

SCALE OF PAY PROPOSED FOR NAVAL MEDICAL OFFICERS.

RANK.	Under 5 years' service.		Above 5 years' service.		Above 10 years' service.		Above 14 years' service.		Above 18 years' service.		Above 22 years' service.		Above 26 years' service.		Above 30 years' service.

* Provided he passes his examination before 10 years' service.

† Or on promotion.

16. That, as a prospect of optional retirement at an earlier period than at present permitted would prove a further inducement to young men to enter her Majesty's service, Naval Medical Officers should be permitted to retire after twenty years' service on full pay; but at the same time, in order to guard the interests of her Majesty's service, the rate of half pay awarded to officers so retiring should not exceed five-tenths of their full pay, and that officers with this service should be permitted to retire on the half pay of their rank, if, after one year on half pay, they are found on medical survey to be permanently unfit for further service.

17. That, as a special reward to officers of long and good service, who, owing to the comparatively small numbers of the inspectorial ranks, have not been promoted to

any higher position than that of Staff-Surgeon, such officers of the rank of Staff-Surgeon as have served for twenty-five years on full pay should, on being compulsorily retired at fifty-five years of age or retired on medical survey, receive the half pay of £1 a day.

The Commission further recommend that competitive examination for admission of Medical Officers into the navy be established at Greenwich Hospital, after the plan adopted in the army, at Chelsea, and that professional instruction by a course of lectures and attendance at Haslar be given to Medical Officers on first entry, in some measure on the system adopted at Netley Hospital.

Some of the medical witnesses have stated that it is desirable that naval boards of survey should be made purely Medical Boards as they are in the army; on this

question, however, the Committee are not agreed, and therefore offer no opinion.

The Report is signed by Alexander Milne, H. B. Phillimore, Douglas Galton, W. O. Markham, James B. Gibson, D.G.; George Busk, and A. Bryson.

Sir James Gibson protests against the greater favour shown to the navy by the above recommendations.

Correspondence.

QUACKS AND QUACKERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

"Miseri quibus intentata nites."—HORACE.

SIR,—In your leading article a few weeks ago are many hints thrown out on the above subject deserving the serious and immediate consideration of every member of the medical profession as to "Who is a Quack?" I think in the abstract most medical men are agreed, although the definition is not so easily expressed. To my mind Walker's ("Dictionary," 1832) is a good one—viz., "Quack.—A boastful pretender to arts which he does not understand; a vain boastful pretender to physick; one who proclaims his own medical abilities in publick places; an artful, tricking practitioner in physick." But as it is not my intention to endeavour to arrive at a perfect definition, I shall say no more on this point, but venture to offer a few hints as to the mode of dealing with these vile pretenders, and believing precept and example should always (if possible) be combined in argumentation, I trust you will forgive me adducing a few examples to prove the truth of the following statements relative to the above subject:—

1st. Regarded in a medical aspect.

2nd. As regards the public in general.

I have known a legally qualified (*not Irish*) medical man see a patient who had been, *and was during treatment at his hands, at the same time, consulting and allowing himself to be "treated" by a notorious quack*, the above alluded to doctor never attempting to dissuade his patient from doing so, although knowing the circumstances well; but I assure you whatever *lapsus memorie* he displayed on this point he did *not* forget to take his fee regularly. To my mind the above conduct was nothing more or less (though covertly) than consenting to and approving of quackery; but between them the damage done to the patient by the one was rectified by the other, and both were benefited in pocket, so neither complained. Again, I have heard of a village practitioner, when asked why he permitted a "quack" in his neighbourhood without cautioning his patients, &c., state that, were it not for the same worthy, he would have very little to do in the way of practice, and what good would come to him by denouncing the quack and thus losing his patients.

When attending lectures in this city, I knew the case of a fellow-student who contracted blennorrhœa, and consulted a quack at that time (1859) well known in the advertising columns of the morning papers, and gave him five shillings. The visit was repeated twice in an interval of a week, but the disease went on unchecked (nothing to be wondered at, the treatment being some "stuff" taken internally and a "wash" to the external parts, which the "Professor" stated to be most potent). But Hygeia refused to be wooed by the bland "Professor," and my friend, having "invested" fifteen shillings, bethought himself of better advice, and disclosed the transaction to a fellow-student, who, being "a third year's man," effected a cure without much difficulty. But my friend, lamenting over the loss of his money struck on a happy idea, which was no more or less than another visit to the "Professor," demanding his money back, on the principle, "no cure no pay." I need hardly state the threat

of exposure contained a more potent spell than all the medicine of the unfortunate "Professor," who, on the departure of my friend, found himself minus £1, which he very reluctantly handed his late patient on a promise from him of no further annoyance.

Now, Sir, when the profession, qualified and unqualified, patronise (however indiscreetly) this wretched class, is it not time for us to look to our ranks and prepare for a war of extermination to purge our land of these pests? And as Government and the new Medical Act have done nothing in the matter, would it not be advisable to inaugurate a meeting of the profession in this city to consult as to the best means to be adopted to have some legislative enactment enforced to put an effective stop to quackery, by imposing heavy penalties on those convicted of practising without legal right to do so.

2nd. As regards the public in general, the question at issue is very extensive indeed, so that I shall only glance at it briefly at present; and firstly, as to the means by which these impostors make themselves known, it is obvious to any one glancing at the columns of the morning papers. Now, as these papers are for the use of, and supported by, the public, the remedy—to have this class of advertisements expunged—is in the power of the readers. Let them demand the exclusion of all such advertisements, and if not complied with by the editor, the way is clear—to exchange for a paper not admitting these obscene articles; and no doubt the desired end will be soon conceded, and all objectionable matter rejected. But however practicable this appears on paper, I fear the public in general would be slow to adopt it, so that perhaps a better mode would be to make an enactment rendering any person putting such advertisements in any public journal liable to heavy fines.

As the newspapers containing these "traps for the unwary" cannot be supposed to come into the hands of every person (and the quack knows well that small pay will not succeed except combined with large custom), the next mode employed is the publication of "a system invented and practised by the 'Doctor,' by which a speedy cure is guaranteed, failure being impossible," and these execrable little books are hawked about the public streets and thrust into the hands of every one willing or not to receive them. While passing through Stephen's-green a few days since I obtained no less than *eight copies* of one of these publications, emanating from an "Accoucheur, Lecturer on Anatomy, Physiology &c. 25th Edition." This sapient work contains the following.

"N.B.—S. L. cautions the public against the numerous quack pretenders in Dublin. They should be cautious before placing their lives in the hands of such impostors."

Warning others, in order to inveigle them into their own net and fleece them at leisure! How long will such things be tolerated? What obstetric hospital, we should like to know, can have given its diploma to such a character, and allowed him to parade it for the purpose of alluring erring mortals to inevitable ruin? Now, Sir, if a young gentleman possessing the mental ability and amount of education in the case I allude to was duped, what effect must such vile publications as the ones referred to be supposed to have over the mental feelings of ignorant and susceptible youths? Some time since I had the curiosity to watch one of these "dens," and I venture to assert few would believe the numbers observed entering during one half-hour; but what struck me forcibly was the amount of "caution" and "watching" practised by the wretched visitors, fearing any one should see them. In one case especially, where a cart drew slowly up to the door, but did not stop till a few doors further up the street, then a respectable-looking farmer and his son (I suppose)—a pale, emaciated, spiritless-looking youth, of about 20 years of age—descended, and whilst the boy secured the horse, the old man cautiously approached the "Doctor's" door,

and, after peering in for a few seconds, entered, and in about three minutes, again coming forth, led in the young man when the "coast was clear." As to their deliberations, we may suppose they were satisfactory—at least to the "Doctor"—as, after the same amount of inspection, the two soon emerged and drove away. Now, Sir, I think the above statement of what I observed on this occasion clearly proves the "victims" in this case knew the "Doctor" was not a legitimate one, and, in addition, shows the disinclination (which I have frequently observed) these unfortunates have to make known their complaints, brought about wilfully by themselves. This is the very cause of these quacks having so many victims; they terrify the unfortunates in the public prints by their obscene publications, then, by promising a speedy and *secret* cure, allure them blindly to their ruin.

Very many instances I could readily relate in proof of the above, but I fear I have already trespassed too far on your valuable space, so will merely draw the following conclusions, which I think may be deduced from the above:—

1st. No journal is deserving of public support which deliberately and wilfully inserts articles emanating from quacks.

2nd. All parties distributing obscene pamphlets in the public thoroughfares to be reported to the authorities and punished according to law.

3rd. An hospital, or portion of one, to be set apart for the treatment of the class of diseases for which these empirics are in general consulted.

Hoping, Sir, that (in conjunction with the statement so ably put forth by you in a late leading article) the few facts—and they are a very few in comparison with all that could be said, even by one comparatively a novice in the profession—so imperfectly recorded above may awaken the medical profession (especially in this city) to take immediate and effective steps to have "Quacks and Quackery" for ever exterminated, and thus terminate this evil, too long an insult to our profession and a disgrace to humanity,—I remain, Sir, very faithfully yours,

JOHN S. A. CUNNINGHAM, L.R.C.S.I., L.K.Q.C.P.I.
Rathmines, February 27, 1866.

THE RINDERPEST OR CATTLE PLAGUE—ITS CURE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have carefully read over the different reports of the English Commissioners and others who have written on the nature, pathology, and treatment of the cattle plague. I am not satisfied with any treatment proposed. It certainly is a contagious and infectious disease affecting the mucous membrane and skin, closely allied to variola, but vaccination has no effect in the prevention of the disease as in small-pox. This cattle plague is essentially a disease of debility, with sinking of the vital powers at a very early stage of the disease, which, if not checked, would soon destroy the animal.

I have had very considerable practical experience in the treatment of the various endemic and epidemic diseases incident to cattle in this and neighbouring localities for the last twenty-five years and more, and have very little doubt, if the remedies which I consider appropriate are judiciously administered—of course, with modifications as to quantity, and according to age, strength of the beast, and other matters, and the stage of the disease considered—that this disease, hitherto so formidable, can be checked, and eventually cured. Now, as to the treatment, I propose to give the following tonic and stimulant dose every four or six hours as required: Take of powdered cinchona bark 1½ to 2 oz. infused in 1 quart of boiling water for two hours, and when cold add fresh powdered carbonate of ammonia, ½ oz.; spirit of camphor, ½ oz., or whisky or rum, 1 glass; porter or ale on draught, 1 pint; all mixed well together. After these remedies have been

administered three or four days, according to circumstances, the animal should get every three or four hours one pint or more of the following mixture:—

Very strong infusion of gentian and cascarrilla, each 1 pint; dilute nitro-muriatic acid, as much as will make these infusions slightly acid.

Should the animal labour under diarrhoea, the following dose will check it:—

Prepared chalk, 2 oz.; powdered catechu and kino, each ½ oz.; powdered ginger and extract of logwood, each ¼ oz.; powdered opium, ½ dr., to be given in 1 pint of warm milk in which a few spoonfuls of fine flour have been blended, and repeated occasionally.

If an aperient or mild purgative is required, give the following:—

Epsom salts, 8 to 12 oz.; flor. sulphur, 2 oz.; ginger powder, ½ oz.; treacle, 4 oz.; all mixed in two or three pints of warm water.

The animal, in addition to these remedies, properly administered according to circumstances, should be covered with a blanket or horse-rug, and should get chloride of soda or lime in suitable doses, at proper intervals, in the common drink. The house in which the sick or infected animal is kept should be scrupulously clean; the temperature should be warm, say from 75° to 80° Fahr. The animal should of course be well supported with nutritive diet, gruel of oatmeal, linseed, and white flour, mixed with milk if possible. Chloride of lime should be very freely sprinkled about the sheds.—I am, Sir, your obedient servant,

THOMAS BURKE, M.D.,
Medical Officer to Scariff Workhouse.

Scariff, February 16, 1866.

CORONERS AND THEIR COURTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I see by your last edition an extract from the *Medical Times and Gazette*, in which it is reported that Dr. Lankester, Coroner, in the holding of a certain inquest incurred the displeasure of a body of men termed "the Vestry," and also a "member of his own profession," so much so "that he was attacked by the Vestry as he seemed to throw all the blame on them for their want of energy, and that by none was he assailed so vehemently as by a member of his own profession." Now, to any one who has read the several reports of inquests at which Dr. Lankester so ably presided, or that was aware of his public usefulness, it should be apparent that there is not a more painstaking, forbearing, and valuable public officer than Dr. Lankester, and I am satisfied that in those cases in which the several suggestions and advices that emanated from his Court were practically adopted, crime was arrested and life was saved, therefore any impartial reader must regret that an angry Vestry and a "member of his own profession" should have "vehemently assailed" the should-be respected coroner. But in my opinion, this "Vestry" and this Medical should have been made understand that a Coroner's Court, which takes precedence in years and in importance before any other, must be respected. I speak not now on the *ipse dixit* of any uninformed person as to the respect which the law insists must be paid to the Coroner and his Court, but I speak on the authority of the Lord Chancellor of Ireland. I would refer the members of the Vestry and the "medical," to read at their leisure (and as corroboration of my assertion) the report of the famous trial in Dublin in 1854—viz., "The Attorney-General versus Orr." It was an application on the part of the Crown to remove Mr. William Olliver Orr from the office of Coroner of county Tyrone, and was made on the suggestion of Mr. Justice Torrens (then going Judge of Assize), who represented to the Government that the respondent was not a proper person to fill the office. Certain charges, apparently of a determined and summary proceed-

ing, and as not having been warranted under the circumstances, were set forth against the Coroner. Amongst these charges was his (Coroner) having ordered the police to take into custody a Dr. B—, who attended professionally at an inquest at which Mr. Orr presided.

The Attorney-General stated the case at length, and Serjeant Christian replied on part of the respondent.

The Lord Chancellor, in a full and able speech, delivered judgment, from which I extract the following passage, *verbatim* :—

“A Coroner has a duty to perform to everyone who comes before him, and must preserve order in his Court, and if he allowed it to be disturbed he would be more unfit to hold his office than a person would be who, over sensitive perhaps, to the dignity of his Court, represses with too strong a hand what he conceives to be a gross contempt. In this case provocation was given. Dr. M— behaved in an indecent and improper manner to the Counsel, and to the Judge, and merited a strong expression of rebuke from the latter, in fact the accusation made by him was one amounting to corruption, and if the Coroner had ordered his instant removal to jail the facts would have warranted him. . . . It may be that Mr. Orr is not altogether free from infirmity of temper, but this is a freehold office, conferred by freeholders. Therefore, under the circumstances, giving all deference to the opinion of Judge Torrens, I feel I am but discharging my duty by telling Mr. Orr to return to the duties of his office, the petition therefore should be dismissed.”

If the above extract should happen to come under the notice of the members of “the Vestry,” and of the Doctor who so “vehemently assailed” Dr. Lankester (Coroner), I hope that before they would again do so they would be induced to chew a toothpick or ruminate a little.—I am, Sir, your obedient servant,
AN IRISH COUNTY CORONER.

NOTES ON THE CURRENT TOPICS OF THE WEEK.

RECENT RESEARCHES ON THE ANTIQUITY OF MAN.

THE difficult question as to the antiquity of man in relation to the hitherto received views of modern geologists, is still earnestly and industriously agitated in this country and on the Continent. Among the evidences that human beings existed upon the earth at an earlier period than that assigned by most geological writers, are the remains obtained by the investigation of several caverns in this country, especially in the county of Devonshire. At the meeting of the Royal Institution of Great Britain on Friday evening last, Mr. Pengelly of Torquay delivered a very eloquent and interesting lecture on some recent researches carried on by himself and a committee appointed by the British Association for the Advancement of Science, on the contents of Kent's Cavern, an excavation in the rocks near Torquay. This cavern has for a long period been the scene of many interesting geological discoveries, and it has been even reported, on apparently good authority, that the bones of man have actually been seen there in conjunction with those of animals now extinct. The late exploration, which formed the subject of Mr. Pengelly's lecture, has not at present confirmed the statement as to the existence of human bones in the cavern; but the flint implements, now so generally believed to have been constructed and used by man, have been found in abundance, and were exhibited to the audience, together with the teeth and bones of recent and extinct forms of mammalia, as lions, bears, elephants, stags, hyænas and others. The examination of this cave has revealed the presence of distinct strata, differing both in their mineralogical char-

acter, and in their organic and other remains; the upper layer exhibiting articles indubitably of human workmanship, as rings and clasps, and the lower layers abounding in the flint implements, in juxtaposition with the animal remains to which we have just referred. Many very interesting problems are suggested by these strange discoveries, and the presence of human implements with the bones and teeth of carnivorous animals, especially those of the hyæna, seems to imply that man and his carnivorous antagonists inhabited these caverns alternately, as they could not have lived there together, and the eroded condition of many of the bones appears to show that they have been gnawed or crushed by animals using them for food. The point in which many of the public are still doubtful is, whether the so-called flint implements were really fabricated by man, or were produced by natural causes; but the presence in Kent's Cavern, of one layer containing remains of undoubtedly human art, and of other and older layers containing the flint implements, together with the appearance of the implements themselves, all seem to prove very clearly the agency of man, although human bones are still the desiderata of the geologist.

THE PROGRESS OF THE CATTLE PLAGUE.

THE new law on the Prevention of the Cattle Plague has not yet come into operation, owing to the fact that, although the Government Bill has passed, and has received the Royal assent, another Bill, proposed by Mr. Hunt, has not yet passed the House of Lords, and it will be necessary to harmonize the provisions of the two Bills before they can become the law of the land. In the meantime it would appear that the disease is not making such rapid strides as it has recently done, but no definite opinion can be at present formed on the subject, as it is said that the returns are imperfect. Dr. W. Farr, the eminent statistician, predicts that the disease will soon come to an end, and he states that the relative weekly number of cattle attacked shows a diminution in comparison with the early periods of the epidemic. Whether the disease is really on the decline, or whether the statements in the papers are fallacious, we cannot decide, but it would seem that more of the cattle are recovering than was formerly the case. As for the specific said to have been discovered by Mr. Worms, of Ceylon, and consisting of several anti-spasmodic substances, we know nothing of its supposed power of checking the disease, and we doubt its efficacy. Our contemporary, the *British Medical Journal*, very properly ridicules the notion that a specific fever can be arrested by swallowing leeks or wearing a collar of onions; but we find a correspondent in that journal of the present week informing the Profession that he can cure the severest forms of acute rheumatism in a period varying from four to seven days. It would be unfair not to state that the treatment said to be so efficacious in cutting short a disease which usually lasts five or six weeks consists in giving a generous diet, administering quinine and opium, and applying counter-irritation to the spine. If acute rheumatism can be cured so speedily we must not despair of finding a remedy even for the rinderpest.

A NEW MODE OF SUPPLYING LONDON WITH WATER.

An eminent civil engineer, Mr. Bateman, has lately published a pamphlet in which he shows that the supply of

water to the Metropolis is rapidly diminishing, while, in consequence of the continual increase in the population, the demand is constantly increasing; and he proposes to form a reservoir near the Welch mountains, from the sources of the River Severn, whence the water is to be brought by an aqueduct to London. The distance being a hundred and seventy miles, the plan appears at first sight to be startling from its magnitude, but as money and engineering skill can accomplish any task, the difficulties are by no means insuperable. The proposal, however, has already met with opposition on various grounds, but chiefly from the enormous expense which it would entail, and the difficulty of raising money enough for the double purpose of completing the engineering works and of compensating the existing water companies for the loss they would sustain. Another source of expense would be the compensation necessary to give to the manufacturers and others on the banks of the Severn who would be injured by the withdrawal of the waters of that river. It is stated, moreover, that the scarcity of water in the present metropolitan watershed has been exaggerated, and that the late deficiency in the supply has been due to only temporary causes.

THE ARMY AND NAVY MEDICAL SERVICES COMMITTEE.

WE publish in another part of the Journal an abstract of the Report lately made by the Committee sitting on the subject of the position, pay, and relative rank of the Medical Officers of the Army and Navy; but in doing so we add a caution that the recommendations contained in the report have not yet been sanctioned by the authorities, and must not therefore be considered as definitively adopted. Under these circumstances we should not have published the Report if that course had not been already taken by one of our contemporaries; but this having been done, we have no choice in the matter. We can only hope that the liberality shown towards our brethren of the Naval and Military Services may be substantiated by the heads of those Departments, and that the ill-feeling and irritation so long existing may now be appeased. To ourselves the concessions proposed in the Report appear to be likely to satisfy the just demands of the Medical Officers, and we should have great cause for rejoicing if our brethren of the Poor-law Medical Service had anything like a similar measure of justice dealt out to them.

MR. WORM'S TREATMENT OF THE CATTLE PLAGUE.

THE third bubble which the *Times* has blown respecting the cure of the rinderpest has burst, and, while it has left no good result behind, it has doubtless done much injury to cattle owners, who have been several times diverted from the prophylactic remedies of the disease. Lord Granville reports that he had sent down an inspector (Mr. Symonds, the veterinary surgeon) to Baron Rothschild's farm, for the purpose of examining Mr. Worm's systematic treatment. Mr. Symonds reports as follows:—

“Veterinary Department of the Privy Council.

“I have the honour to inform you that I went down to the seat of Baron Rothschild, for the purpose of investigating the treatment of animals affected with cattle plague, as adopted by Mr. Worms. On the 9th instant, a heifer gave indication of illness. Mr. Lepper, of Aylesbury, recognised some of the earlier symptoms of cattle plague, and as such the animal was placed as soon as possible under the care of Mr. Worms. Notwithstanding all the attention which it

received, it died on the fourth day of the attack. On Saturday, the 10th instant, two other heifers were also said to be attacked with the plague, and consequently were placed aside by themselves. On Monday one, Tuesday four, and Wednesday (the day of my visit), three more of the herd were removed, as being likewise the subject of the plague. The ten animals were also placed under the care of Mr. Worms. The early cases were reported to me as having been cured, and the others as going on most satisfactorily. It required but little knowledge of the diseases of cattle to at once see that none of the ten animals had been, or were the subjects of any serious disease; and after giving to each of them a careful examination, I failed to detect the slightest symptom of cattle plague in any one of them.”

Lord Granville draws the very strange deduction from the letter, considering that Mr. Symonds distinctly declares that none of the ten animals had been or were the subjects of any curious disease, that although the result was not conclusive it was rather favourable than otherwise.

The *British Medical Journal* vehemently inquires:—

“Is it in accordance with anything science has taught us to believe that, when a specific fever has got possession of a man, has poisoned his whole system, has altered every globule of his blood and every fibre of his body, a few leeks in his belly or a string of onions about his neck can arrest the fermentative, or whatever sort of process it is which is going on there? Of one thing Mr. Worms may be very sure—viz., if he can prove his case, he will have made the greatest discovery ever yet made in medicine. But great discoveries in medicine have never yet been made in this kind of way—by the importation of specific cures from Ceylon or of puceoon from Canada. Great discoveries in medicine have always been made by master minds in medicine—not by village wise-women, nor amateur physiccabblers, nor Drs. Dulcamara.”

THE CATALOGUE OF THE ROYAL COLLEGE OF SURGEONS IN ENGLAND.

WE have received from a correspondent the following communication in reply to a request from him for information as to the large gratuitous distribution of the College Museum Catalogue, which was noted in the columns of THE MEDICAL PRESS AND CIRCULAR. It seems paradoxical that, if the College be in a position to present a copy of their Catalogue to every provincial hospital in England and Wales, the same courtesy should not be extended to Ireland, inasmuch as by such refusal a very large number of its own members, resident in Ireland, and who, having contributed, have a right to expect the same privileges as their brethren in England; are deprived of the knowledge of the contents of the Museum which they are entitled to visit. If the Council of the College have burned the inch they might, we think, with more advantage “burn the candle,” and it would be well that the resolution should be amended by its extension to Ireland:—

“Royal College of Surgeons of England, London, W.C.,
February 19, 1866.

“SIR,—In reply to your letter of the 17th instant, addressed to the Curator of the Museum of this College, inquiring how you ‘should proceed in order to obtain a catalogue of the Museum of this College such as is supplied to provincial hospitals,’ I have to acquaint you that the resolution of the Council respecting the presentation of the catalogues of the Museum of this College, to which your attention has probably been called by an unofficial and incorrect report in some of the medical and other journals, has reference only to the libraries of all recognized provincial hospitals and medical schools in England and Wales, and that its scope does not extend to recognized hospitals and schools in Ireland.—I am, Sir, your obedient servant,

“EDWARD TRIMMER, Secretary.”

THE NEW ANÆSTHETIC APPARATUS.

REPORTS say that Dr. Richardson's new refrigerating apparatus for producing anæsthetic cold by ether spray has been employed with most gratifying success. It has been tried in operations for fistula in ano, phymosis, excision of a tumour, evulsion of toe-nail, and all with almost complete relief from pain, and so far no injurious result whatever. The sensation of the freezing process is variously described, some patients declaring that it was not unpleasant, others that it was sharp and burning.

CONVERSAZIONE AT THE ROYAL COLLEGE OF SURGEONS, EDINBURGH.

ON Friday night last one of those pleasant and instructive reunions which were inaugurated some years ago, was held within the rooms of the Royal College of Surgeons, Neilson-street, where, at the invitation of the President (Dr. Dunsmore) and the Fellows of the College, a large and distinguished company assembled at eight o'clock. Although the subject of lecture was more of professional than general interest, there were nevertheless amongst the party a goodly number of distinguished men—medicals,—including representatives of the sister professions—the church and the law. But by far the larger portion of the audience was composed of medical men from Edinburgh and from the provinces, who had, in spite of other great attractions in the city, preferred to spend an hour or two amongst old friends and familiar faces, and listen to a paper by one whose attainments are well known.

The visitors were received by the President in the Museum, where a short time was pleasantly passed in examining the large and rare collection of anatomical and pathological specimens belonging to the College. The company then adjourned to the Lecture Room, where, after a few words of kindly welcome by Dr. Dunsmore, Dr. Balfour proceeded to read his paper entitled "The Nature of Disease, as Explanatory of the Success attending various Modes of Treatment," and which shall appear in our next number. It is not so generally known as we think it ought to be, that long ago, before the present champions of what may be called the restorative treatment of inflammatory diseases had given up blood-letting, Dr. Balfour, for the first time in Britain, drew the attention of the profession to the results of an opposite plan of treatment which he had seen pursued with success at Vienna. At that time he was assailed by those who now are amongst the most energetic opponents of bleeding, as wishing to introduce a "do-nothing" plan in the treatment of inflammation; and it was said that if such a method was attended with success in Vienna, it could lead to nothing but the most disastrous consequences if adopted in this country. A mighty change has swept over the professional mind since then, and we think that some credit is due to Dr. Balfour for having been the first to have had the boldness to advocate a system which is now almost universally adopted.

The paper was listened to with the greatest interest, and the beautiful and philosophical style of the composition was thoroughly appreciated. A vote of thanks (proposed by the President of the Royal College of Physicians and seconded in an excellent speech by Lord Deas, who frequently honours the conversazioni with his presence) was conveyed to Dr. Balfour by Dr. Dunsmore; and, after

partaking of refreshments in an adjoining room, the company broke up.

We wonder very much that the College of Physicians does not hold such meetings as this, which tends so much to the promotion of friendly intercourse, as well as the acquirement of knowledge.

BETHNAL GREEN AGAIN.

ON Monday week the Middlesex Coroner resumed an inquiry, opened upon view of the bodies of an infant aged 9 months, and Mary Clarke aged 36 years. The child died at No. 7, Leonard's-buildings, Friars-mount, and the woman Clarke at No. 3, Reform-square. The jury found that the house No. 7, Leonard's-buildings, was occupied by a family, eight of whom had been attacked with typhus fever. The jury then crossed the black and fetid roadway of Friar's-mount to Reform-square, a court not larger than an ordinary room. The house, No. 2, was occupied by nine persons—all had the fever, and the father was dead. At the door of No. 3 stood a boy, who took off his cap and showed that all his hair had been shaved off for fever. He stated that twelve persons occupied the house, and that seven of them had typhus. In the case of George Potter, Mr. Rumbold, surgeon, said he attributed death to inflammation of the lungs, and the jury returned a verdict of "Death from natural causes." In the second case, George Clarke, a sickly-looking ragged man, said he was a canewasher, and that the woman White lived with him as his wife. They lived in one of the two rooms of No. 3, Reform-square, for which they paid 2s. 3d. a week rent. The room below was occupied by a man and his wife and three or four children. The water flowed into the house from the pavement of the square. The deceased had been ailing for some time past. On Saturday week he found her lying on the floor, and very ill. He put a sack and other things over her, there being no blankets or counterpane, and he went for Mr. Haycock, the parish doctor, but he could not come without an order. He went to the workhouse to get one. Mr. Arnott, the relieving officer, was out, and he was told the master was ill, and he should wait for an hour. He went home and found deceased dead. She used to have enough of food. Four or five persons had been taken away out of the place to the Fever Hospital. Stephen Knight, messenger at the guardians' offices, said that he remembered the man Clarke coming at one o'clock in the day for a medical order. One of the relieving officer's pauper attendants told him that Mr. Arnott was out. On the brass plate on the door the hours for application were stated to be from 9 to 10 a.m. and 5 to 6 p.m. Unless the relieving officer chanced to be detained at the office no order could be got except during those hours. On Sundays no order at all could be obtained. Mr. John Baker, 7, Elm-terrace, Cambridge-heath, said that he was the landlord of Reform-square. He had been served with a notice from the parish authorities on the 26th of January. He had eighteen months ago put the place into thorough repair, at a cost of £120. Mr. F. J. Gant, pathological anatomist to the Royal Free Hospital, said that he made a post-mortem examination of the body of the deceased, and found the cause of death to be disease of the brain. But the condition of the place in which she lived would tend to accelerate death. The room in which she and another person lived contained 8·2 cubic feet of air; and the room underneath, in which seven persons lived, had a cubic space of 819 ft. Now, the *minimum* allowance consistent with health was set down at 800 cubic feet for each individual. Defective drainage, the accumulation of vegetables and other refuse, and the state of the closets would produce typhoid fever. Typhus and typhoid fevers were eminently preventible diseases. Mr. George Haycock said that he was divisional surgeon of Bethnal-green. He said that by the rules of the Poor-law Board he could not attend a patient without an order. He had attended persons in four houses in that square. Typhus and typhoid had been raging there. He had eighteen cases in two houses. He inserted the facts about Reform-square in his medical relief book, which he sent to the guardians about three months ago. A dustbin was erected and a closet emptied, but nothing else was done until within the last fortnight. Dr. Sarvis, medical officer of health for Bethnal-green, said that he dissented from Mr. Gant as to 800 cubic feet being the *minimum* quantity of air necessary for health. A meeting of medical officers had decided that 800 feet was sufficient in dwelling houses. Mr. C. A. Christie, sanitary inspector, said that on the 17th of last month, while walking down Mount-street, he saw water flowing across the pavement out of Reform-square, and he went up and made an inspection. He found the place very filthy, and when he found out the landlord he served him with notices, which were not yet fully complied with. The Coroner, in summing up, said that it was manifest that the condition of the houses in question was such as to engender disease and cut short life. The jury returned a verdict,—“That the deceased was found dead from the mortal effects of disease of the brain, and that her said death was accelerated by overcrowding, want of sufficient water supply, defective drainage, the dirty and unhealthy condition of the premises, and general neglect of sanitary arrangements, and the said jurors do further say that the intimation made by the medical officer of the district of the condition of the premises ought to have received immediate attention, and that greater facility should be afforded to the poor in obtaining medical orders in urgent cases.”

THE THREATENED CHANGE IN THE QUEEN'S UNIVERSITY.—We understand that the Committee of the Graduates' Association have resolved to send a deputation to London to press their views on the Education question upon Earl Russell and Sir George Grey; and that one of the graduates is to proceed immediately to London to make preliminary arrangements.

PROFESSOR SYMES, who has been recently confined to the house by indisposition, is again able to attend to his professional duties.

Parliamentary Intelligence.

HOUSE OF LORDS—FEB. 19TH.

CATTLE DISEASES BILL.

ON the motion of Earl GRANVILLE the Cattle Diseases Bill was read a second time, and the standing orders having been suspended the House went into committee on the Bill.

The Earl of AIRLIE moved an amendment to the 12th clause giving to the local authorities a discretionary power to slaughter or restrain from slaughtering animals certified to be recovering from disease.

The proposal gave rise to some debate, in which the Duke of ARGYLL, the Earl of DERBY, the Duke of RICHMOND, and other lords took part, and ended in a division and the rejection of the amendment by 52 to 15.

An amendment proposed by the Earl of LICHFIELD, to the effect that the inspector should be required to assign a reason for entering a farmer's premises prior to his inspection, and not afterwards, was also negatived, upon a division, by 22 to 21.

The Bill then went through committee, and was read a third time and passed.

FEB. 20TH.

The Royal Assent was given by commission to the Cattle Diseases Bill.

After some conversation respecting various points in connexion with the cattle plague,

LORD DERBY inquired what measures had been taken to prevent the spread of the small-pox in sheep, which had recently broken out in Northamptonshire?

LORD GRANVILLE replied that measures had been adopted which it was hoped would prevent the extension of the disease; and, in answer to further questions, he stated that at present it had not been precisely ascertained whether the disease had been imported from abroad.

HOUSE OF COMMONS—FEB. 19TH.

THE House having gone into Committee on the Cattle Plague Bill, which relates principally to the movement of cattle, Mr. WARD HUNT explained that his object had been to endeavour to establish a code that would be sufficiently elastic to apply to every county in Great Britain. The Bill would absolutely prohibit the movement of cattle on all highways, railways, rivers, and canals, up to the 25th of March next—with these exceptions only, that beasts might be conveyed along a highway from one farm to another for 200 yards; where landed from a sea-going steamer they might travel on the highway for 500 yards; and in going from the farm to the slaughter-house they might traverse on the highway not exceeding two miles. Newly-dropped calves might be conveyed in carts from the place in which they were born to the farms where they were to be reared; working oxen employed in the cultivation of the soil and in harness, which was some security for their being in health, might also be moved for a distance to be specified; and to enable emigrant and other sea-going ships to get a supply of milk on board, milch cows might be conveyed to them in covered carts. By adopting these precautions he hoped the plague would be got within manageable compass by the 25th of March. From that date it would be necessary to still further relax the restrictions upon the movement of cattle. Then incoming tenants took possession of their farms, and he proposed that beasts for the stocking or restocking of farms might be moved by licence at any time during fourteen days from any quarter-day after public notice. For the purposes of breeding, a cow or heifer might be moved with a licence for any distance not exceeding three miles, and a bull twenty miles. In like manner calves might be removed provided they were sound and not more than twenty-one days old. The consideration of the clauses was then proceeded with.

POOR-LAW MEDICAL RELIEF.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have now in the hands of the printer the draft of a Bill containing seventeen clauses, with a commentary on each clause, pointing out the reasons for their proposition. There is also a letter addressed to the members of Parliament, bringing all the important points of the subject prominently before them. A copy will be sent to each medical officer who has sent a subscription to the Association within the last twelve months, as well as to each member of Parliament, as soon as the Bill is brought before the House. If any of your readers can assist me by naming a gentleman willing to undertake the charge of the Bill, I shall be glad to hear from him. The printer informs me he cannot keep the type standing; I therefore trust that those medical officers who intend subscribing will do so without delay, so that I may order the numbers of copies of the pamphlet actually required for them.—I am, &c.,

RICHARD GRIFFIN.

12, Royal-terrace, Weymouth, Feb. 17, 1866.

List of subscriptions received by Mr. Griffin:—

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a general meeting of the Fellows, held on the 19th inst., the following gentlemen, having undergone the necessary ex-

amination, and satisfied the College of their proficiency in the Science and Practice of Medicine, Surgery, and Midwifery, were duly admitted to practise Physic as Licentiates of the College:—

- Burn, Joseph, Bourne.
- Cribb, Henry, Bishop's Stortford.
- De Tatham, Hamilton, 40, Dorset-square.
- Edgelow, George, Kensington-square.
- Jackson, George, Plymouth.
- Morrill, John, Guy's Hospital.
- Webb, John Holden, St. Mary's Hospital.

At the same Meeting the following gentlemen were reported by the examiners to have passed their Primary Examination for the Licence:—

William Percival Magor Boyle, Guy's Hospital; Henry Cheesman, ditto; Charles Gôte Gurden, ditto; James Robert Hill, St. Mary's Hospital; William George Kemp, St. Bartholomew's Hospital; George Welland Mackenzie, London Hospital; John William Morris, Guy's Hospital; Arthur Wolcott Nankivell, University College; John Ockenden, St. Mary's Hospital; John Robert Perkins, King's College; John James Ridge, St. Thomas's Hospital; Eldred Noble Smith, St. Mary's Hospital; John Davies Thomas, University College; William James Todd, King's College; Arthur Tudor Humphreys Trevor, ditto.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 15th inst.:

- Bolt, Robert Andrew, Blackman-street, S.E.
- Edmonds, Charles George, Southampton-street, Camberwell.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Names of candidates who passed the Major Examination, February 21st, 1866, as Pharmaceutical Chemists:—

- Thomas Fitzgerald Bulmer, Preston.
- Osborn Chubb, Taunton.
- Thomas Harris Cruse, Warminster.
- Walter Dyson, Pendleton.
- Arthur Thomas Horton, Scarborough.
- Edward Jones, Ryde.
- Andrew MacInnes, Ardrossan.
- James Stewart, Kirkcaldy.

MEDICAL DIARY OF THE WEEK.

WEDNESDAY, FEB. 28.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Prof. Huxley, "On the Classification and Structure of the Mammalia."

THURSDAY, MARCH 1.

ROYAL INSTITUTION.—3 p.m. Professor Frankland, "On the Non-Metallic Elements."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8 p.m. Anniversary Meeting.

CHEMICAL SOCIETY.—8 p.m. Mr. C. R. Wright, "On the Chemical Action of Sunlight."—Prof. Church, "On New Cornish Minerals."

HARVEIAN SOCIETY OF LONDON.—8 p.m. Mr. Broadbent, "On Prognosis in Heart Disease."

FRIDAY, MARCH 2.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Prof. Huxley, "On the Classification and Structure of the Mammalia."

ARCHAEOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—4 p.m.

ROYAL INSTITUTION.—8 p.m. Mr. G. Scharf, "On Portraiture; its Fallacies and Curiosities as connected with English History."

SATURDAY, MARCH 3.

ROYAL INSTITUTION.—3 p.m. Rev. G. Henslow, "On Systematic and Structural Botany."

ADVANCED PAYMENTS.

SUBSCRIBERS are reminded that their subscriptions in all cases must be paid within two months of the date of the order to secure the advantage of the lower rate of £1 1s. 8d. per annum, and that any subscription delayed beyond that period will be charged on the credit scale of £1 2s. 6d. per annum.

NOTICES TO CORRESPONDENTS.

- Mr. J. R. Greenway.—The paper has been received.
- Mr. Griffin.—The letter has been received.
- The Harveian Society.—The report has been received.
- Dr. Fraser.—The paper has been received.
- The Royal Institution.—The notice has been received.
- The Pharmaceutical Society of Great Britain.—The list has been received.
- Mr. Bateman.—The paper has been received.
- The Army Medical Department.—The list is inserted.
- Mr. B. R.—The *actea racemosa*, which is said to be a remedy for rheumatism, belongs to the natural order of ranunculaceae.
- Expectans.—We have not yet heard of any date being fixed for the next meeting of the Medical Council.
- A. B.—We have not much confidence in the efficacy of the remedy alluded to.
- A Chemist.—Methylated spirit, in its chemical action, is very similar to rectified spirit of wine, and where economy is a great object, perhaps no great harm may ensue from the substitution.
- C. K.—We shall have pleasure in accommodating the libraries when they subscribe. We cannot send free copies.

MEDICAL APPOINTMENTS.

- B. C. GOWING, M.R.C.S.E., has been appointed House-Surgeon to the Whitehaven and West Cumberland Infirmary.
- C. C. POPE, B.A., of Exeter College, Oxford, has been elected Radcliffe Travelling Fellow.
- W. H. REED, M.R.C.S.E., has been appointed Assistant Medical Officer to the Derby County Asylum.
- H. TRIMM, M.B., has been elected a Fellow of the Linnean Society.

BIRTHS.

- OGLE.—At Upper Brook-street, London, the wife of J. W. Ogle, M.D., of a son.
- BRUNTON.—At Caledonian-road, London, the wife of John Brunton, M.D., M.A., of a daughter.
- NUTT.—At Sherborne, the wife of Horace Nutt, M.R.C.S.E., of a daughter.
- BRISTOWE.—At Queen-square, Westminster, the wife of J. S. Bristowe, M.D., of a daughter.
- MAIN.—At The Grove, Lasswade, on the 16th inst., the wife of William Main, M.D., of a daughter.
- BORMAN.—At Derby, the wife of Allan Borman, M.R.C.S., England, of a daughter.
- BROSTER.—At Southampton, the wife of Edward B. Broster, R.N., prematurely of a daughter.
- GAINS.—At Newcastle, Jamaica, the wife of George E. Gains, M.R.C.S. Eng., Surgeon 6th Royals, of a daughter.
- GREENWOOD.—At Penryn, Cornwall, the wife of N. Greenwood, L.R.C.P.L., of a son.
- HICKS.—At Oldstreet-road, the wife of Dr. G. Borlase Hicks, of a son.
- JONES.—At Dolgelly, the wife of Edward Jones, M.D., of a son.
- LONG.—At Leamington, the wife of C. F. Long, M.D., of a daughter.
- RIDING.—At 36 Euston-square, N.W., the wife of Dr. Riding, of a daughter.
- TIZARD.—At Weymouth, the wife of Henry Tizard, M.D., of a daughter, prematurely.
- WALKER.—At Peterborough, the wife of Dr. T. J. Walker, of a daughter.
- WATKINS.—At 11 Chandos-street, W.C., the wife of C. S. Watkins, M.R.C.S., Eng., of a son, stillborn.
- MACKAY.—At Elgin, N.B., the wife of J. W. N. Mackay, M.D., of a daughter.

MARRIAGES.

- MOUNCEY—WILSON.—On the 13th inst., James Ainley Mouncey, Surgeon, to Emily Argyleana, daughter of William Wilson, Esq.
- RUSSELL—TIMM.—On the 13th inst., at Sheffield, J. Bussell, M.R.C.S.E., of Neath, Glamorganshire, to Elizabeth Mary, daughter of Charles Timm, M.D.
- CURTIS—ASHBY.—At Staines, Albert Curtis, M.R.C.S. Eng., to Augusta, daughter of the late Charles Ashby, Esq.
- GARSTANG—WARDLEY.—At Over Darwen, Walter Garstang, M.D., to Matilda Mary, second daughter of James Wardley, Esq.
- ROSS—NIGHTINGALE.—On February 17, John T. Ross, M.R.C.S., R.N., to Mary Julia, second daughter of the late T. Nightingale, Esq.

DEATHS.

- HOLTBY.—At Whitby, Katherine, the wife of G. H. Holtby, L.R.C.P. Ed., aged 59.
- FOSBROKE.—W. M. M. Fosbroke, M.D., of the Old Kent-road, aged 50.
- MORRIS.—Dr. William Morris, of Newbury, Berkshire, aged 51.
- HUNTER.—At Fountainville, Belfast, on the 10th of February, Samuel Hunter, M.D. Edinburgh University, Licentiate and Fellow of the Royal College of Surgeons in Ireland, aged 51 years.
- TAYLOR.—Suddenly, at Barnhill, on the 16th inst., James Taylor, Esq., M.D., aged 22 years.
- BOYD.—At 284 Argyle-street, Glasgow, on the 18th inst., Henry Boyd, Esq., M.D., aged 54 years.
- WILLAN.—At Duncan-street House, Newington, Edinburgh, on the 18th inst., Jessie Madeline, the beloved wife of Reginald Moore Willan, Esq., Surgeon, Newton-on-Trent, Lincolnshire, youngest daughter of the late William Graham, Esq., M.D., formerly of Calcutta.
- COWPER.—At 126 Nethergate, Dundee, on the 19th inst., of typhus fever, James A. Cowper, M.D.
- FAIRBAIRN.—At Melbourne, Australia, on the 12th November last, Dr. Thomas Fairbairn, late of Edinburgh, in his 54th year.

ON THE NATURE OF DISEASE,

AS EXPLANATORY OF

THE SUCCESS ATTENDING VARIOUS SYSTEMS OF THERAPEUTICS.

A LECTURE DELIVERED BEFORE THE ROYAL COLLEGE OF SURGEONS, EDINBURGH.

By GEORGE W. BALFOUR, M.D., F.R.C.P.,

PHYSICIAN TO THE ROYAL PUBLIC DISPENSARY, EDINBURGH.

MR. PRESIDENT, MY LORD, AND GENTLEMEN,—There is nothing in the whole circle of biological science that appears more remarkable to the inquiring mind than the incontrovertible fact, that in different ages, and even in the same age, in the hands of different practitioners, similar diseases have been found to be amenable, and have been successfully treated, with fair average results, by therapeutical methods diametrically opposed to each other, in the principles upon which they are based, and in the subordinate objects sought to be attained by them. To the purely professional mind this fact seems even more striking, because it, of course, is best acquainted with the nature of those plausible pathological theories upon which these practices have been based, and it therefore is more fully aware of the contradictions involved even in the apparently similar amount of success found to attend each of them. Having solemnly devoted their lives to the elucidation of the questions connected with vitality for the benefit of their fellow-men, the medical profession dare not shirk the responsibility thrown upon them by this anomalous state of matters, and though the public may be contented to revile medicine as a whole, or to swear by the prevalent doctrine of the day, it is the duty of the profession to eschew all such narrow-minded and time-serving sentiments, so derogatory to their own dignity and usefulness, and by taking wider views of the history of medicine and of the relations of disease to life and health, on the one hand, and to the various modes of therapeutics on the other, at least to endeavour to solve the problem so forcibly brought before them, and which they know to be so intimately connected with the well-being of mankind. For we know that the advancement of truth in medical science is inseparably connected with the welfare of our species, because, though men may shut the door in the face of the doctor, they cannot exclude his art. For, as Hippocrates long ago remarked in his work *Περὶ Τεχνῆς*, "It is true that the sick are sometimes cured without the aid of a physician, but not therefore without physic. They have done certain things—they have avoided others; if they have regulated themselves by certain rules, these rules have been those of art; if they have blindly trusted themselves to chance, it has only been in so far as they have by chance approximated to the procedure of good medicine that they have been rescued from their danger. In dietetics as well as in the use of medicaments useful or dangerous methods may be followed. Both prove the stability of art; the one injures by its improper employment, the other succeeds by a proper use; but what is proper and what is improper being quite distinct, art must exist, for if it did not, the destructive and the useful would be confounded." Thus, though we may pettishly deprive ourselves of all the advantages to be derived from the medicine of the present, we cannot wholly escape from the medical art, and in attempting to do so we can now-a-days hardly avoid falling back upon some exploded theory of the past, or coddling ourselves with the

rejection of some extinct pharmacopœia. We may revile the medical art as unsafe and uncertain, but in declining the services of men of learning and reputation, we act at our own especial peril, and only ensure that such medical art as we may employ shall be of a specially unsafe and uncertain character.

Within the last twenty years there has occurred in this country a change in the treatment of disease, which, from its contrariety to immediately preceding doctrines, and its wide-spread character, not less than from the fact of its having happened within our own immediate cognizance, as well as from the influence which it is yet destined to exercise upon our views of the nature and treatment of disease, has completely eclipsed in magnitude and importance all similar changes. My own immediate connexion with this change of practice has been so close and intimate as to have forced upon me in an especial manner an examination of the nature of disease in its bearings upon medical treatment, as explanatory of the success of various therapeutical methods, and I purpose now laying before you as concisely as possible the conclusions to which that examination has led me.

In the first place, however, it may be interesting to many of my audience who may have forgotten, or may never have known, what was the nature of medical practice twenty years ago, for me to go cursorily over this portion of medical history, so as to point out in what this change of treatment consists, and how it has been explained by others, before proceeding to give my own views upon the subject.

In 1846, then, my late revered preceptor, Dr. Alison, still continued to teach what he had published in his "Outlines of Pathology" in 1844, that in pneumonia, "uncomplicated and recognized from its commencement, the utmost confidence may be placed in general blood-letting;" and that "in such a case judiciously treated in this way"—by repeated venesections—"the only essential action of the prognosis is the day of the disease when the treatment is commenced, the remedy being often ineffectual when it is delayed more than two or three days from the decided commencement of the disease." While such was the deeply-rooted belief in the incapacity of the powers of Nature to cure disease, that even a professor of pathology chose to yield himself a convert to the curative powers of infinitesimals rather than suppose that acute diseases could naturally terminate in health. Sydenham's estimate, that the detraction of forty-five ounces of blood was about the average amount required to meet the danger of a decided pleurisy, was regarded as not exaggerated, and was often far exceeded. We read of a slender young girl being bled to forty-eight ounces by a distinguished surgeon merely for a supposed inflammation in the chest, and of 192 ounces being taken from one individual, who, in consequence, was several months afterwards weak and miserable, and it appeared doubtful whether he would ever regain his health. Seventy or eighty ounces was the usual amount detracted at one operation by those who were termed the champions of heroic practice, and from twenty to thirty ounces at once, and repeated within the twenty-four hours, was by no means above the average treatment of inflammatory attacks in healthy and robust individuals. While such was the dread of inflammation and its consequences, and such the faith reposed in this active mode of treating it, that, as we learn from the records of the past, patients were often placed in no small danger by the very means by which their safety was sought to be ensured. "On one occasion early in life," writes Dr. Mackintosh, an ardent champion of heroic practice, "I very nearly lost a patient from whom I had taken, at different times in the course of four days, 120 ounces of blood, but who recovered after the exhibition of stimulants; and I have seen several cases within the last ten years, to which I have been called in, where considerable injury had been inflicted by very large bleedings, the medical attendants having allowed themselves to be misdirected by the continuance of dyspnoea, which increased after each abstract on of blood."

Throughout the whole of these histories of the past we find ample proof that these risks were run, not by careless neophytes, but were so inseparable from the system as to be encountered even by men whose names afford the most perfect guarantee alike for their skill and for their considerate thoughtfulness. And all this risk was run that inflammations might be cured quickly, safely, and effectually? Not so. For all that the ablest authorities have claimed for bloodletting is that, except in a few rare instances, it *merely disposes inflammations to a favourable termination*. And yet when, in 1847, for the first time in the case of a modern British medical audience, I brought forward the opinion, based on upwards of four hundred recorded cases, nearly two hundred of which had been observed by myself, that inflammations generally, and pneumonia in particular, did not require for their successful treatment the use of any of these so-called heroic remedies, especially bloodletting, which were then so lavishly employed, I was met by the statement that "nothing was better established than the good effects of bloodletting in the acute pneumonia of Edinburgh, whatever might be the case in Vienna." *Ten years afterwards*, however, when these views had time to leaven the mass of practitioners, one of my then opponents thus wrote:—"It is admitted . . . that the practice of bleeding in acute inflammations has, within a recent period, undergone a great change; that whereas it was formerly the rule to bleed early, largely, and often repeatedly, now such bleeding is rarely practised, and is *not necessary*."

The practical part of the question having thus been settled, it became of importance to explain the cause of this change of treatment, not only for the satisfaction of the present, but also for the instruction of future ages. One party, headed by Dr. Bennett, alleges that an improved method of diagnosis and an advanced knowledge of pathology have enabled us more correctly to ascertain the actual mode of origin and progress of disease, and thus more skilfully to adapt our means to the end sought to be attained, and to eschew all that is dangerous and superfluous. But, not to waste time on unnecessary reasonings, I may state that this claim is effectually and conclusively quashed by the recorded facts; that Dr. Bennett's work on "The Pathology of Inflammation" was published in 1844, and that in his speech subsequent to the reading of my paper just referred to before the Medico-Chirurgical Society of this city in 1847, as it is reported in the *Edinburgh Monthly Journal of Medical Science*, of which he was at that time the editor, he stated that, "Dr. Balfour had attempted to establish the benefits of a 'do-nothing practice' from the results of statistics;" and he concluded by strongly condemning the system of practice "lately sought to be introduced by Dr. Forbes and others, founded upon fallacious statistics, to the exclusion of pathology, diagnosis, and the experience of the most eminent men." It is impossible to show more clearly and convincingly, than by the simple statement of these facts, that improvement in pathology and diagnosis had nothing whatever to do with the origination of this improvement in the treatment of disease. Though I willingly grant that the advances made of late years in the diagnosis of disease and in the knowledge of its pathology, a very large part of which is due to the untiring energy of our present distinguished Professor of Physiology, have undoubtedly furthered the spread of this change of treatment, by rectifying many of the mistakes into which an unaccustomed refinement of physical diagnosis had led physicians, as well as by enabling us more clearly to understand the *modus operandi* of the treatment employed.

Another party, comprising most of the seniors of our profession, have agreed that this great change in the treatment of inflammation depends upon an equally complete change in the type of the disease; it (they say) no longer possesses the same virulent and sthenic character as formerly, and therefore no longer requires the same heroic remedies. This is so simple and comprehensible a solution of the difficulty that at first sight it is readily received; but the only proof our seniors have referred to in its favour

is their recollection, and we all know how deceitful a thing mere memory is, and how difficult it is to recognize in some tiny streamlet the dark rolling river of our earlier recollections, and the case is not otherwise in regard to disease. Fortunately, in regard to both matters, we can test the correctness of our memory by an appeal to unchanging facts. In the one case, the actual dimensions of the bed of the brook furnishes us with the required standard; while in the other, those very symptoms which are supposed to betoken the change of type may be profitably compared with the identical symptoms as they were recorded at a time when bloodletting was supposed to be the only necessary remedy. Now, the symptoms supposed to indicate this change of type in inflammatory disease are just the general asthenic character of the disease; and, second, the soft and compressible character of the pulse when contrasted with that "*frequent, full, hard, firm, and quick (i.e., sharp) pulse*," that vehement action of the heart and incompressibility of the pulse which is supposed to have characterized the pneumonia of Cullen and of Gregory—that is, of the days when inflammation was, if it ever was, most truly sthenic, and when it at least bore bloodletting well, whether it required it or no. Now, as a very good, and at the same time a very striking example of this treatment, I may mention that quite recently an octogenarian told me that having in his younger days been assaulted and stabbed in Leith-street, he pursued his assailant along Princes-street, till he fell faint and exhausted from loss of blood, at the head of the Lothian-road. Then he was carried into a house, and the distinguished surgeons of the day, the Messrs. Bell, were sent for. Their assistant was promptly on the spot, and the first thing he did to this man already faint, and exhausted from loss of blood, was to bleed him from the arm *to prevent inflammation!* In the library of the College of Physicians here there are several volumes of MS. notes of clinical lectures, both by Cullen and Gregory, most of the cases related being precisely such as we find in hospital now-a-days, only there are a good many cases of intermittent fever, and from the absence of our modern precision of diagnosis, of course a considerable—but no ways remarkable—number of cases of inflammatory fever and catarrh, none of which escape the inevitable bleeding on two or three days successively after admission, and that though the pulse is very often stated to be soft, not always full, and sometimes under 100; Cullen now and then *naively* congratulating himself that the case had not turned out nervous fever, in which case, he adds, "*the bleeding would have been pernicious*." Obviously the soft state of the pulse and the asthenic character of the disease had no deterring influence upon him. Nay more, there is in these lectures one particular case, which I shall take an early opportunity of laying before the profession, which exhibits this even more clearly. It is a case of pneumonia, admitted and treated for fever, as many cases unquestionably were in those days, just as in our day very many still find their way as fever cases to our hospitals, though they cannot get out of them in these days of stethoscopes and pleximeters without being recognized. This case was unfortunate. The patient died, and Cullen makes some excellent remarks in connexion with it upon the fallibility of physicians, and expresses his regret that its true nature had not been recognized during life, that a treatment more appropriate to the actual disease might have been employed. Thus expressly stating that it was *to the disease and not to the symptoms* that the treatment was applied. Just the reverse of what is implied in the theory of a change of type, and just the reverse of what is argued by all the advocates of this theory. Dr. Gregory also, in a most interesting clinical lecture, distinctly lays it down as a rule that, "in pneumonia the pulse is remarkably soft, though the febrile symptoms run very high." And, again, he says: "In respect to the fulness of the pulse in pneumonia, in the beginning before the patient is bled, it is not only *soft, but small*; but commonly upon the patient being bled, it becomes fuller, though it always retains its softness."

This simple record of facts, as they occurred at the time, is of course a surer guarantee for the actual nature and symptoms of the disease, as it was then observed, than any mere remembrances of the past by any physician however eminent, and from what I have just now curtly stated, as well as from the fuller reports of the cases treated which your time does not permit me to quote *in extenso*, but which I have elsewhere published, it is obvious that the facts we possess give no support to the opinion advanced that there has been any change of type in inflammatory disease since the days of Cullen. Nay more, if a change of type be necessary to explain the success of a non-evacuant system of treatment in inflammation, it ought by a parity of reasoning to be necessary to explain the success of a similar treatment in cases of simple catarrh, of parturition, and of accident by precipitation, drawing, &c., in none of which is the formerly inevitable lancet now employed.

And if the retrospect of only a few years suffices to teach us the fallacy of the opinion that a change of type in disease is the efficient cause of this remarkable change of treatment, a wider survey of the history of medicine serves only to confirm this view. For we find that though there have been in all ages certain medical men who have lauded bloodletting as the only remedy for every ill, and have counted their triumphs by their bleedings, there have been others also not less known to fame, and not less entitled to credit, who have regarded bloodletting as a source of much evil, and have sought to banish it altogether from practice; and these two classes of medical men have not succeeded one another as wave after wave of varying type swept over the face of disease, nor has the latter class—the non-bleeders—only recently arisen, basing their heterodoxy upon the feeble and typhoid manifestations of disease in a worn-out age. No; from the earliest era of medical science there has never been a time when these two classes of practitioners have not existed side by side; so much so that at times whole cities have been divided in partisanship between the physician, the advocate of bleeding, and the physician its foe.

The followers of Pythagoras, the Cuidian Chryrippus, and of Erasistratus, objected to bleeding as useless and injurious; while those of Prascagoras, Kerophilus, and Galen, regarded it as the most useful of remedies. At Rome, in the second century, the followers of Erasistratus were so numerous and so distinguished that it was personal far more than abstract scientific controversy, that prompted Galen to write his two celebrated theses—*De venæ sectione adversus Erasistratum*, and *De venæ sectione adversus Erasistrateos*, and neither practice ever wanted distinguished expositors till with the fall of Rome the long night of ignorance settled down on the world. After the rebirth of science we find these two sects still fully represented—Van Kelmont, and Portius, and Stahl on the one side, with Botalli, Stoll, and many others on the other, down to the commencement of the present century, when Dumangier, of La Charité, almost never bled for pneumonia, yet his success was at least equal to that of Corvisart, who bled largely. Laennec thought he had annihilated the mortality of pneumonia by large doses of tartar emetic at the very time that Gregory thought that large bleedings could alone cope with so formidable a disease; while Bouillaud, then as now, placed implicit confidence in his *coup-sur-coup* method of bleeding; and Alison taught that in the treatment of pneumonia, “uncomplicated and recognized from its commencement, the utmost confidence may be placed in general bloodletting, which should always be large,” at the very time that Skoda of the Vienna Hospital, taught that pneumonia was a disease tending not so much to dissolution as to resolution, and that rapid restoration to health was best promoted by withholding all those heroic remedies generally prescribed, and amongs them bloodletting. Moreover, the success which during the last sixty years has undoubtedly attended the treatment of acute diseases with homœopathic globules by Hahnemann and his followers, affords a convincing proof

sults of treatment, as well as of the inutility of the theory of a change of type to explain the success of a change of treatment; because it reduces the argument to a dilemma, which is this:—Either the homœopathic globules are truly active and energetic remedies, or the partisans of bleeding have been grossly mistaken as to the fancied utility of their favourite remedy in inflammation of every type; for the last sixty years includes the period (1805-20) when the inflammatory type was supposed to culminate, yet we never hear of a time when the globules, in the opinion of homœopaths, failed to do good service, nor of their being more suited to one type of inflammation than to another; nay more, their very opponents never raised this question, and the whole literature of the controversy contains not one word about change of type till the success of the expectant mode of treating inflammations forced venesectionists to seek for some reason for this success more soothing to their intellectual pride than a simple confession of error.

It is unquestionable that we owe much of our present knowledge of the powers of nature in the cure of disease, as well as the present revival of the system of treating inflammations without bleeding, to homœopathy, and we need not hesitate to acknowledge our obligation even to a system of quackery; for not only, as Leibnitz has wisely said, “is every error but a truth abused—all partial systems, but contributions to a perfect science,” but also this is not the only instance in which the Medical art has been reminded by quackery of her legitimate duties as the handmaid of Nature. A very remarkable and interesting example of this is to be found in the history of the powder of sympathy in the cure of wounds in the early part of the seventeenth century, which was at first ridiculed by all men of sense, till on trial it was found to be actually more successful than those plans which proceeded upon what were then thought to be scientific principles; and it continued to gain ground in the public estimation, until at length some innovator ventured to try the experiment closing the wound, and keeping it clean and cool without the application of the sympathetic powder to the sword. And Wiseman, who wrote about fifty or sixty years after the introduction of this mysterious operation by Sir Kenelue Digby, in describing the importance of keeping the divided parts in union, says: “For here Nature will act her part, by the application of blood and nourishment to both sides indifferently, and finish the conlities without your further assistance, and this is that which gives such credit to the sympathetic powder. As surgery in those days, so has medicine now been taught a wholesome lesson by what seemed at first sight to be diametrically opposed to all the rules of science. No new truth was revealed in either case, but old and well-known ones were brought so prominently forward as to ensure them attention after the chaff which obscured them had been blown away by the breath of inquiry. Surgery has never forgot her lesson. Let us hope that medicine shall prove equally mindful, and she shall never have cause to rue the day when her practice met with such a rebuff, and even her principles seemed so rudely shaken. But, as the art of medicine is unavoidable and necessary, so it is utterly inconsistent with all that we know of divine law and government to suppose that her principles can be otherwise than eternal and unchangeable; at times they may seem so, but we may rest assured that this only arises from the partial and limited views which we take of the nature of disease, for all the various divine systems of therapeutics which have prevailed in by-past times have been based upon discordant views of what disease essentially is, and our only hope of obtaining a key to the science of therapeutics lies in the greater or less success which may attend our endeavours to answer the question, ‘What is disease?’”

The most prevalent conception of the nature of disease is to regard the morbid phenomena, not so much as the vital expressions of a suffering organism, as the function of a new and superadded personality preying upon and

the organic power, is supposed to be fighting with this personality, and the function of the physician in such an emergency is aptly stated in the following apologue related by D'Alembert: "A blind man armed with a club, that is the physician," he says, "comes in to settle the difference, the first tries to make peace; when he cannot accomplish this, he lifts his club and strikes at random; if he strikes the disease, he kills the disease; if he strikes Nature, he kills Nature," that is the patient of course. This haphazard method of cure, as it is termed, is entirely inconsistent with enlightened views of what disease essentially is, and completely at variance in its tendency with that mode of treating disease which may be said to be based upon these views, but which really arises naturally out of them, and which at once approves itself to the intellect as founded in truth. For if scientific medicine be not a chimæra—and all our knowledge forbids the supposition of such a negation of truth to what forms so necessary and so unavoidable a part of man's existence here—then its basis must be sought for in those relations eternally subsisting between organized matter and those agents which influence its condition in regard to the manifestation of vitality, and the key to the whole science of therapeutics must be to be found in a due appreciation of the causes of those phenomena which we term life, of which health and disease are but two separate phases, widely diverse at the opposite extremes, but intermediately merging into one another.

"In all the states of life, however, man and other animals differ from themselves in their dead state, or from any other inanimate matter, in this property alone; they can be affected by external agents, as well as by certain functions peculiar to themselves, in such a manner that the phenomena peculiar to the living state can be produced." This peculiar power or property is, therefore, as is universally acknowledged by all physiologists, the cause of all the phenomena of life as exhibited in living action—of life the *ζωη*, as the ancients termed it; as it is in its turn the result of the connexion of matter with life the *ψυχη*, a potentiality only found in connexion with "the reproductive cells derived from the first parent or first parents of every species in the organic world," and therefore never found apart from organized matter.

This susceptibility to the action of a stimulus is the sole cause of living action, alike in the simplest cell and in the most complicated organism. In its simplest form—as exhibited in adult animals consisting solely of cells, or in the embryonic forms of animals of a higher type—it is observed wholly unconnected with any nervous tissue; while in its highest manifestation—thought—it is found in connexion with the very highest development of the nervous system of which we have any knowledge. The obvious and legitimate inference from this is, that its existence is wholly independent of the nervous system, though certain parts of that system are as unquestionably developed for the sole purpose of giving expression to its higher manifestations. It is simply a mode of being of matter, the result of the placing of the molecules in certain relative positions by the Spiritus Rector—Life the Psyche, whereby that potentiality manifests itself as simple irritability in the muscles, as a secreting power in the glands, as a thinking power in the brain, as life everywhere. It may be defined in strict accordance, I believe, with all that physiology teaches us, to be a diffuse *vis cusita sen nervosa*, which the nervous system is created, not for the purpose of supplying, but of coördinating in accordance with the requirements of organic life, just as the blood is not generated by the heart and bloodvessels, but exists as a diffuse nutritive fluid long before any trace of a circulatory system can be observed; this system being gradually supplied to meet the various wants of each particular organism, precisely as the nervous system is gradually developed and differentiated into several subordinate centres in accordance with the requirements of each organism as it ascends in the scale of being.

The susceptibility to the action of a stimulus depends

not, therefore, on the existence of a nervous system, but of a nervous force—a nervous force one and indivisible, identical with mind upon the one hand, and with life upon the other—while the nervous system is created for the sole purpose of coördinating the various impressions received, so as to constitute one homogeneous organism of a creature composed of various organs.

When the reactions produced by the vital stimuli take place smoothly and unconsciously, the organism is said to be in a healthy condition; for "good health consists in a pleasant, easy, and exact use of all the functions;" while disease is the reverse of this, and "consists in an uneasy, difficult, or disturbed exercise of all or any of the functions." These terse and clear definitions we owe to the pen of John Brown, who, "scorned and reviled as is, for the most part, his memory," yet gave the first blow to the doctrine of life being a mere "vital spark of heavenly flame." And they are entirely in accordance with the opinions of medical men from the days of Celsus downwards, and cannot be improved upon by greater particularization. For as life itself is a state of ceaseless change, so is health also one of constant mobility; and the man who "can live without rule, and needs not the doctor," will not care to investgate whether his tongue be *nivida*, *non vero nimis rubra*, nor enter into any other similar minute inquiries.

In perfect accordance with the definition just given, health may also be defined to be the normal result of the normal action of certain specific stimuli upon certain specific susceptibilities; and, in like manner, disease may be regarded as the equally normal result of the abnormal action of the same or similar stimuli, and therefore as the necessary complement of life, just as death is its inevitable result.

For, as every act by which the imperishable *ψυχη*, life, manifests its existence in the organic frame is attended by the molecular death of a part of that frame, and as the replacement of these molecules entails in turn such an amount of friction and loss of power as must sooner or later—wholly independent of any other causes—ensure from purely physical laws, the total cessation of all these living actions, so it is that death—somatic death—is the inevitable result of somatic life. "Passing away" is the motto of our present state, written in blood on every organ of our body, just as, for similar reasons, it may be traced imprinted on everything around us, or read in characters of fire emblazoned on the deep blue vault of heaven above.

Under certain circumstances life may for a short period remain latent, as it is termed, though still attached to the organism; but its existence can only be truly ascertained by the manifestation of living actions, and for the production of these, not only an organized body animated by life, the Psyche, but also the action of certain vital stimuli is requisite. These necessary vital stimuli are, temperature, a certain amount of heat, air, and aliment, including both food and drink. While, though these stimuli are absolutely necessary for the production and maintenance of living actions, yet, for wise and obvious purposes, the organism is able to withstand considerable variations in their actions, although more considerable variations, in regard to excess or defect produce various morbid phenomena, such as those of insolation, starvation, or suffocation—phenomena which, though not usually termed diseases, are unquestionably such in character; inasmuch as they are "such deviations from the natural condition of the body as cause suffering and inconvenience, and endanger life" (Alison). Thus, though perhaps it is scarcely correct to say that disease is the necessary complement of life, seeing we are not all of necessity diseased, yet it is true that by the very fundamental laws of our existence, we are all of necessity exposed to disease; not as to the attacks of some unnatural entity sent to punish and to prey upon frail humanity, but simply as the necessary result of the conditions upon which our present vitality depends, and arising from the failure or excess of those stimuli necessary for its manifestation.

Further, as we know that these vital stimuli act within certain necessary and unavoidable limits of variation without disturbing health, so there is every reason to believe that what we term disease is but, as it were, a more prolonged and intensive series of those compensating organic changes by which health is maintained under these circumstances. It is obvious that this view of disease is fraught with most important therapeutic considerations; according to it we must regard the *vis medicatrix nature*—the healing power of Nature—not as the manifestation of any power inherent in the organism, and antagonistic to disease, but simply as the disease itself, which tends naturally to the re-establishment of health in every case, and only fails to do so in any case from the powers of the system being inadequate to the completion of the necessary cycle of organic changes.

At first sight such a view of the nature of disease would seem to discourage all attempts to cut it short—to cure it, in common language—and to limit the endeavours of physicians to the aiding and assisting of Nature, so as to hasten and ensure the satisfactory completion of those organic changes of which the morbid phenomena are but the external manifestation. But a deeper insight into the nature of those processes teaches us that this is not the case, but that merely to aid Nature is but a small part of what it is the duty of the physician to do, and but a small part of what lies in his power to do.

But there is one point which this view of the nature of disease, and of the unavoidable existence of the medical art, places in its true light, and it is this, that the undoubtedly favourable results attained in the treatment of similar diseases by many diverse systems of therapeutics has not necessarily resulted from the equally useful or equally useless character of all, since that is impossible, but rather that the vital powers are so constituted as to compensate for that absence of vigorous precision common to all our plans of treatment, and unattainable, indeed, in any sublunary matter. Nature—as we are accustomed to say—like a skilful workman, does the best she can with the means at her command, while the judicious practitioner, on his part, knows well the true nature of the present state of theory, and therefore knows well when to stop in his application of it. But the theory of disease just propounded exhibits the cause of Nature's seeming intelligence, and is capable of the widest application in explanation of the success of diverse systems of treatment, for it shows us that even the worst, kept within due bounds by the educated intelligence of the practitioner, can have no more injurious influence than merely to prolong the course of the disease. For, while the wheels of life move on, all the vital processes move on also, and as disease is not merely one of these, but is their sum, the result of the abnormal action of one or other of the normal stimuli to vitality, so its ultimate and normal gradual differentiation into health—the normal phase of life—cannot be prevented by anything short of the destruction of the organic unity.

From this we learn the importance to mankind of a liberal medical education. The mere empirical application of remedies to symptoms is a matter common to all quackish pretenders to medical knowledge as well as to the profession; but it requires nothing less than an education based upon the whole circle of medical science, and involving an accurate knowledge of the laws of vitality and the modes in which these are influenced, to know when to stop in the use of remedies. And there is, perhaps, nothing in the domain of medicine which more strikingly illustrates the advances made in recent years in a knowledge of these laws than the fact that now-a-days a mere tyro in medicine can readily avoid those shoals and rocks past which a Cullen, a Gregory, and a Mackintosh had the greatest difficulty in steering.

It is also obvious that this doctrine also gives a fatal blow to quackery of every sort by showing the utter worthlessness of mere numerical statistics—mere lists of cures—in proving the value of a remedy. If, as we have seen and know, a disease may be recovered from under

many and various modes of treatment, any number of mere recoveries, however large, must be insufficient to prove the positive utility of any remedy in any given disease, and if they can be held to prove anything at all it is but, at the utmost, the caution and skill of the physician in the employment of the particular remedy in question. The time occupied in recovering, and the condition of the patient after apparent recovery, are far more important elements in estimating the true value of a remedy than any mere numerical average, although, of course, in the case of any truly useful remedy, these three results must always be coincident.

Did your time permit, it would be easy to show that, as the normal action of temperature, air, and aliment is necessary to the manifestation of healthy life, so their abnormal action is also the cause of those morbid phenomena of vitality which we term disease, and even to trace the links of that causation, but to do so would far exceed the limits of a single lecture.

I might further point out that if we connect these views of the causation of disease with the doctrines of pathological development advocated by Virchow, which are every day receiving fresh confirmation and wider acceptance, and which may be concisely described as deducing all new growths, from the pus of an abscess to a cancerous tumour, by ordinary generation from the germs of pre-existing normal tissues, while the doctrines formerly prevalent supposed that they became developed within the organism by a species of *generatio equivoca*. These, the words of one of the most earnest and unwearied truth-seekers that ever existed, who has not long since passed from amongst us, acquire a deeper and a truer meaning than even he intended when he said, "that disease, contrary to the vulgar notion of it, is no new thing superadded to the living body, and constituting a special entity in *serum natura*, but is a mere group or collection of modifications of structures already existing, and of actions always going on in a living system. Whatever be the remote or exciting cause of the morbid state or disease, whether external to the body or originating in the body, the morbid state itself is always the product of the body itself—that is, of the vital actions always taking place within it, and of the materials of which it is normally composed" (Forbes). While I might also show that the views advocated are entirely in accordance with the tendency of modern medicine, to attempt the cure of disease by endeavouring to influence the nutrition of the part through the agency of the nervous system, which, as Travers says, "forms the portal as well as the herald of all diseased action," and indeed of all vital action whatever, the manifestation of which depends upon the nervous force of which the nervous system is but the visible coördinating agent. Though they also distinctly point out that to cut short or cure a disease we must neutralize the action of the injurious stimulus *in limine* before time has been permitted for the development of those organic changes, the course of which we can never hope to check, and which indeed all our present knowledge of pathology teaches us it would be injurious to check, even if we could do so, but the unpleasant phenomena connected with which we may moderate, while at the same time we cautiously aid Nature, as need arises, in the completion of these necessary changes.

In conclusion, I would desire to point out how important it is in regard to the preservation as well as the restoration of their own health, that the public should be thoroughly indoctrinated with the principles of physiology. Not so much that they should be taught a mere smattering of the structure and functions of the various organs, in regard to which it is so difficult to convey to them any knowledge that is either correct or practically available, but rather that every man and woman amongst them should be taught the principles of what may be termed dynamical physiology, the science of the influence of all the external agents surrounding us in regard to the production of the phenomena of life, whether healthy or diseased. That is,

a subject which could be readily elucidated by practical illustrations, and easily explained in language comprehensible by any mind of ordinary intelligence. The spread of a correct knowledge upon this matter throughout the mass of mankind, could not fail to be productive of a material increase in their well-being, while it would tend also to increase the dignity and usefulness of our profession, who would then cease to be regarded, as they too often are, merely as a class of privileged nostrum-mongers, and would be raised to their rightful position as the counsellors and advisers of mankind.

REMARKS ON

DR. RICHARDSON'S NEW METHOD OF PRODUCING LOCAL ANÆSTHESIA.

By GLASCOTT R. SYMES,

ONE OF THE SURGEONS OF STEEVENS' HOSPITAL.

DR. HARDY many years ago drew attention to the production of local anæsthesia by means of the vapour of chloroform directed in a fine stream on the part affected. In many cases the result was most satisfactory, as in facial neuralgia and toothache; but gradually this method fell into disuse, probably from too much having been expected from it at the outset.

After this it was usual to produce local anæsthesia by the application of a freezing mixture. The difficulties in the way were numerous, the method was cumbersome, the patients screamed with the pain while the tissues were being frozen, and again a second time when the blood returned to its fluid circulating condition, and the process took considerable time.

It is well known that ether produces a considerable diminution in the temperature of any body with which it may come in contact, in consequence of the rapidity with which it evaporates. The amount of caloric rendered latent for the fulfilment of that process can be measured by the rapidity and completeness of the evaporation.

The smaller the particles of the ether of course the larger surface would it present, and the more rapid would be the evaporation. In this way Dr. Richardson, of London, conceived the idea of utilizing the ether in the form of spray. He adopts a form of spray producer, of which the following is a description:—

“The apparatus consists simply of a graduated bottle for holding ether; through a perforated cork a double tube is inserted, one extremity of the inner part of which goes to the bottom of the bottle. Above the cork a little tube, connected with a hand bellows, pierces the outer part of the double tube, and communicates, by means of the outer part, by a small aperture, with the interior of the bottle. The inner tube for delivering the ether runs upwards nearly to the extremity of the outer tube. Now, when the bellows are worked, a double current of air is produced, one current descending and pressing upon the ether forcing it along the inner tube, and the other ascending through the outer tube and playing upon the column of ether as it escapes through the fine jet. By having a series of jets to fit on the lower part of the inner tube, the volume of ether can be moderated at pleasure; and by having a double tube for the admission of air, and two pairs of hand bellows, the volume of ether and of air can be equally increased with pleasure, and with the production of a degree of cold six below zero.”

Such is the instrument as manufactured by Messrs. Krowe and Seseman. I have heard that it is patented.

I endeavoured to get one of these instruments in Dublin last week, but the demand was so great that the stock was run out. I therefore determined to try what I could effect by using Dr. Clark's ordinary spray producer with the mountings for directing nitrate of silver on the glottis; with this and a small bottle to hold my ether I was enabled to produce the very same effects as Dr. Richardson alludes to. The ether must be as perfectly anhydrous as possible. It should have a specific gravity of 0.723; it should boil in the warmed hand. Such an ether is not always to be had, but my friend Mr. Tichburne, of the

Apothecaries' Hall, manufactured it for me with great care. By directing the spray on the bulb of a good thermometer the mercury went down to six degrees below zero in three minutes; by removing it the thermometer flew up ten degrees in as many seconds; the water in a test tube was congealed in three minutes. When directed on the back of the hand momentary pain was observed, but in one minute total insensibility was induced, so that the prod of a needle or knife was not felt. The return to the natural condition of the circulation was unaccompanied by pain such as is felt where the freezing mixture has been applied.

On the 24th inst. I used it in the removal of a portion of toenail from a case of syphilitic onychia. The patient winced at the first application but did not appear to mind the cutting, although my incision went very deep; there was no bleeding, and the parts cut as if composed of cheese. The patient was much gratified and said it was much better than the chloroform which he had inhaled on a former occasion for the same operation. I since then opened an abscess without the patient feeling any pain.

Dr. Richardson deserves the best thanks of the public for his invention; it will be the means of saving many a person from death by chloroform, which almost always follows some minor or bloodless operation. The plan is being extensively tried in London with the very best and most flattering results.

It is, however, open to a grave objection. When the stream of ether is applied for any time, say four minutes, to the back of the hand and then the part is pricked with a needle, a curious phenomenon is observed; commencing at the point touched, a white patch is instantaneously produced, which travels to the extent of the surface which has come in contact with the spray. The part is now completely frozen, it is hard and brawny, and returns when the spray is withdrawn to the condition of the surrounding parts in about one minute. The explanation of this phenomenon I take to be as follows:—If a fluid be kept quite stationary, its temperature can be lowered to many degrees below its ordinary freezing point without that effect being produced; but on the slightest disturbance it becomes solid instantaneously; so here the blood was stagnated, but not solid until it was disturbed by being set in motion by the prick of a sharp-pointed instrument; or it may be that the vaso-motor nerves were irritated, so that the vessels were emptied of their contents; but I rather incline to the former explanation. However, no matter what the cause, the effect was the same. I tried it on some of the students and myself, and the next day the part was red, sore, and in the very same condition as a burn of the first degree. If this be the condition induced on the sound skin when freezing takes place, what, I argue, must be the condition of an open ulcer or surface which is so treated? It certainly will not be improved.

It then occurred to me to use chloroform in those cases where the surface is exposed. Chloroform used in the form of liniment is extensively and successfully used every day on the surface of the body. I accordingly substituted some of Duncan and Flockhart's good chloroform for the ether, and found that on the skin its effects were nearly as satisfactory as the ether. Thus after one minute the back of the hand was rendered insensible to the prick of a needle. It acts both by lowering the temperature and as a narcotic and sedative. It could never freeze the living tissues, but makes up in its other and ordinary anæsthetic quality for the complete effects produced by the cold of the ether. I intend to use it in the next case where I have an exposed or ulcerated surface to deal with. The subject is, however, in its infancy. The apparatus I have hitherto used is Clark's spray producer for the larynx; owing to the weight of the chloroform it must be held with the point downwards and not elevated.

Dublin, February 24, 1866.

[Since writing the above I have operated on many cases with the aid of local anæsthesia. On comparing Clark's

instrument with that of Dr. Richardson, I am still inclined to use the former; the spray it produces is much finer than that showered from the nozzle of Dr. R.'s instrument. I do not find the tube is clogged with ice.—G. R. S.]

OBSERVATIONS UPON PAU,

SANITARY, MEDICAL, AND ECONOMIC, AS A WINTER RESIDENCE

FOR ENGLISH CONSUMPTIVE INVALIDS.

By CHARLES R. MAXWELL, L.R.C.P.Lond. and Edin.

(Continued from page 169.)

As regards the quality and prices of things in general use—bread, butter, milk, candles, soap, tea, coffee, eggs, about the same as in England, also butchers' meat. Fresh fish from Biarritz is sometimes offered for sale "au marché;" I have never seen it, but have occasionally been made aware of being its vicinity; I never had the courage to taste it. English ale, Reading biscuits, and many other English commodities are to be bought; I have tried them and found them much deteriorated by shaking *in transitu*. The prices are high; if you know the price of an article in England, double it and you have the price here.

Manufactured goods, especially of superior finish or durability, are universally inferior to those produced in England. They make a native beer here; it would be called "swipes" with us. There is a notion existing in the minds of some enthusiastic Frenchmen having wines to sell that their light wines will be adopted by our labouring population instead of beer, but I think I know the good sense and good taste of that class of my countrymen too well to believe that such will ever be the case; whenever it does take place the "star" of England will have set.

Insect life is abundant at Pau; fleas swarm everywhere, as a young French lady whom I chanced to come across told me, they are in the very dust of the ground; they are extremely persevering. Exhibitors of the "industrious animal" might recruit their stock here *ad infinitum*. Pau also possesses, in the summer and autumn months, a small black fly, very active, which attacks any exposed part; its pique raises a lump about the size of a pea, the itching of which for nearly a fortnight is positively distracting; to refrain from scratching, quite impossible; I have scars on my legs therefrom I shall carry to the grave. I tried various applications to lessen the pruritus; liq. potassæ ʒi, aq. dest. ʒii., I found the best, but the plan I found most successful was to pierce the spot where the sting had penetrated with a very finely-pointed needle and squeeze out the virus, soaking it up with blotting-paper. So much for pests by day. By night mosquitoes of gigantic size will take care you shan't sleep much; your face and hands in the morning are covered with lumps like variolous pustules (less the pus). Apply the same lotion.

Don't let any "piscator" coming here promise himself glorious sport in the river and streamlets. A French lady assured me there was nothing in them but goujons.

The changes of temperature at Pau are very great and very sudden. Early in October, 1865, after great heat, rain fell during the night; the next day, about mid-day, I walked out clad in the cloth surtout I had been wearing, and was glad to hurry in and put on an overcoat, it was so cold. This lasted for two days; it then became as hot as it was before. On the 13th of December I was sitting out in the open air with an umbrella over my head to keep off the sun; the thermometer must have stood in the shade at 50° Fahrenheit. I saw many specimens of a small and beautiful butterfly sporting about, only seen in England in the summer. During the following night a sudden change took place; the morning was frosty, foggy, with an easterly breeze, though slight. It was as keen and cold as in January in England; the glass must have been down to 32° in the shade; however, there was no sun visible. This lasted several days. Here was a fall of 18° in temperature in twelve hours. What will consumptive patients

say to that? I cannot think that a climate subject to such great changes can be beneficial in phthisis. I am convinced that Pau is *not* the place for such. Two ladies whom I met in the Isle of Wight had passed a winter at Pau, and had since then passed two at Ventnor; they said they found Ventnor much warmer than Pau. Mons. Louis, a distinguished French physician, praised the climate of Pau, in phthisis. He had a son thus afflicted who passed some time here. I believe he is buried in the cemetery. I wish to offer a few words of caution to those invalids who sit much in the open air; the favourite spot for such is the elevated ridge in the park overlooking the low ground in front, with the river and streamlets flowing through it. I would remind them that where there is running water there is more or less of a current of air, and that the hills behind them on the north are sufficiently near to cause a current to set towards the valley. They are thus exposed to the partial application of both heat and cold, the intense solar rays imparting the former to their faces and chest, the cold north air rushing through the gulleys behind them, the latter to their backs, base (root) of the lungs, &c. With not a very limited experience in the treatment of phthisis, I have yet to learn that it is good for a consumptive patient to be *entre deux vents*. I shall be told that the Park is a valuable feature *in re Pau*; that it is a source of health to some. Let me not be its detractor, but add, and a source of health to others. Patients sit there much too long in the afternoon. In November, December, January, and February, half-past three is the latest moment they should remain there. They will find a great change between the southern ridge and the streets of Pau to get to their houses, as regards the sun's influence. By the middle of January the sun acquires great power, the air remaining cold. This I found to be most dangerous weather, slight exercise causing perspiration, liable to be checked by the chilly air. I was constantly getting a sore throat, and I believe cyananche to be very prevalent here at all times, at least I was told so, and have no doubt whatever on the subject. French physicians praise the sulphurous waters of the "Eaux Bonnes" in consumption. I have no faith in them. A lady living in the same house with me, who had been several years under the care of one of them, came in last autumn from the "Eaux Bonnes" after suffering great fatigue from the journey; she died two months afterwards. One of the best places on the Continent for pectoral affections, I should say, was Mentone, maritime Alps, but the expense of living there is quite ruinous to any but "grandes bourses." In all the published remarks I have seen on the climate of Pau, its drawbacks have been greatly ignored. Hiatus valdè defendendus, surtout au point de vue médicale. In writing my observations, I have had no preconceived opinions to maintain; no ulterior views to promote; no local interests to defend; I went to the place a stranger; I left it a stranger; my only wish is, in a few words, to place a plain statement of facts before the public according to my impressions, and leave them to draw their own conclusions. In the matter of housekeeping, I wish to draw attention particularly to the dishonesty of *cuisinières* and butchers. I quote from a number of the *Pau Indicateur* just published, where it is stated that servants have made their employers pay eleven francs for a leg of mutton for which they have paid the butcher five francs. This quite equals the dishonesty of English servants; the butchers connive at the fraud. To remedy this evil a company has established *une Boucherie Agricole*, with a tariff of prices, according to the price of cattle. The butcher is bound to furnish a note to the purchaser of weight and price. Insist upon your servants demanding the note, and patronize the Boucherie Agricole, in the Rue Serviez, No. 4. Decision is necessary in dealing with cooks, *et id genus hominum*. Be firm, and show you are *not* a French roll.

There is an English newspaper edited and published at Pau by an old retired military officer that, I believe, every English family makes it a point of honour to take in. It is well got up; some of its "Joe Miller's," under the

heading of "Facetia," reminded me of "The days when we went gipsying, a long time ago." In concluding my remarks on the trade of Pau, I wish to animadvert on the great length of time (fifteen days)—the period allowed by the railway company—for heavy goods to be on their way from Paris, as merchandise pays a less tariff by *slow train* than by passenger. No doubt this is done to act as a discouragement, and induce the trade to send goods by passenger trains at a high tariff. I wish also to somewhat modify my remarks on the enthusiastic praises bestowed on the goods they have to sell by shopkeepers, &c. Everything in this world is by comparison; what appears, and really is, poor and paltry to me as an Englishman, coming from a country filled with superior artisans, workmen, &c., to the French eye, accustomed to look upon so much trash and inferiority, may, in fact, seem to be what he calls it, when he says, "*Voilà, tout ce qu'il y a du plus rare, du plus fort, du plus élégant, plus gentil; et multa alia.*"

The distinguishing feature in the climate of Pau is the almost invariable stillness of its atmosphere. On the tops of the tallest trees (poplars) not a leaf stirs. In consequence of this, the peripheral extremities of the nervous system, not being stimulated by the contact of fresh air, the respiratory process is less active. Thus, the lungs, the great purifying organs of the blood, are comparatively quiescent; but as the blood must be purified, or it would cease to circulate, the duty falls upon the next great decarbonizing organ of the body, the liver, which, being thereby overtaxed, at first functional disturbance, and then organic changes take place therein, thus deranging the secondary assimilating processes, producing dyspepsia, and the elaboration of unhealthy blood, deficient in plastic elements not suited for the nourishment of the body. Then follow nervous and muscular debility, emaciation, and a various train of evils: the pale, pasty, œdematous faces of the town inhabitants, their lack lustre eye, their want of energy, in thought, word, and deed, afford ample testimony to the enervating effects of the climate in which they reside. Those living in the country are better off; their faces are copper-coloured from the sun; their skin dry and shrivelled, and a man at forty looks as old as one of sixty in England. The heat during the months of September and October is very great and oppressive; during November and December the temperature is extremely pleasant, like a fine English autumn; January and February are very cold. No invalid must think of arriving at Pau before the first week in November, and should be away again by the middle or end of March. After mature consideration, and to sum up, I should say that a person in tolerable health, who did not mind a long and fatiguing journey, might pass those four months more agreeably at Pau than in England; but with regard to cases where there is positive disease, debility or irritability, I should say that, could it be proved that life was prolonged, or suffering mitigated by a winter at Pau (and the crowded state of the English burial ground seems to indicate that much which had been expected from climate had not been realized), to make the case my own, I would infinitely prefer the *chance* of existence being somewhat abbreviated by a residence in England, surrounded by the comforts of family, home, and country, than the *certainty* of its being rendered more or less miserable by a long journey and a residence at Pau, or indeed any foreign country. So little difference is there between the mean temperature of Pau and the Undercliff (Ventnor) in the Isle of Wight, and the houses, windows, and door fittings, &c. &c., are so much better calculated in England to keep out the cold that I believe, all things considered in a sanitary point of view, Ventnor will be found to fulfil all the conditions of which "climate" is capable in the treatment of tubercular consumption.

In those cases, where the sea passage to the Isle of Wight might be either disagreeable or inadmissible, on account of sea-sickness, I would wish to draw attention to Worcester, a town in the west of England on the Severn. It is situated in what I will call a topographical basin, surrounded by moderately high hills of gentle ascent,

and very much sheltered from both north and east winds; being inland, the changes of temperature are not so sudden and great as at the seaboard. The numerous walks through the fields and drives in the country command views of scenery not to be surpassed in any part of England. The town itself is well built, well paved, lighted with gas, excellent drainage, abundant water supply, and possessing a local government, which carry out all sanitary measures admirably, leaving nothing to be desired. Its shops are excellent, no article of either necessity or luxury but can be obtained as well as in London. It possesses an excellent market, many churches, and a cathedral, triennial musical festival, frequent concerts, occasional balls, races twice a year, is in the centre of a good hunting and fishing country, plenty of quiet society, and an intelligent and respectable population; it is a cheerful town, without any of the noise and bustle to be met with in what may be styled a fashionable place of resort. The air is mild, yet not relaxing, and I believe a permanent residence there would be the means of preserving and imparting that good state of general health upon which the well-being of an invalid depends more than upon a climate of high temperature considered *per se*.

CLINICAL RECORDS, ILLUSTRATIVE OF THE DISEASES OF CHILDREN.

By G. STEVENSON SMITH, L.R.C.S.Ed.,

RESIDENT MEDICAL OFFICER ROYAL EDINB. HOSPITAL FOR SICK CHILDREN.

III.

CASE OF SCARLATINA RHEUMATICA, OR DENGUE, COMPLICATED WITH PLEURISY.

DENGUE, or scarlatina rheumatica, is the name given to a disease which Dr. Aitkin describes as combining an exanthematous eruption ushered in by fever, with a rheumatic or neuragic state. It is said to be of frequent occurrence in the East Indies and the Southern States of America, and prevailed in an epidemic form in Virginia in 1861.

Though in this country it is not known as an epidemic disease, Dr. Richardson and Dr. Wilks have noticed cases in which well-marked rheumatism of the joints occurred during an attack of scarlet fever. Dr. O'Connor, too, in the *Lancet* of November 16, 1860, gives the particulars of a case of scarlatina complicated with acute rheumatism, in which bronchitis and pericarditis supervened, and the patient recovered.

In the following case a sharp attack of articular rheumatism existed for about a fortnight previous to the appearance of the eruption, which was similar to that of scarlet fever. The rheumatic symptoms disappeared almost entirely for about ten days, but returned with increased severity four days after the rash was observed, and were followed by a sharp attack of pleurisy of the left side. The patient, however, made a good recovery.

J. L., a red-haired, arthritic-looking girl, aged 9 years, was admitted to the Children's Hospital on January 2nd, 1865, suffering from acute rheumatism of the ankle joints, which were slightly swollen. The pulse was quick, skin hot and dry, and the tongue loaded. Under the use of the tincture of the *actea racemosa*, in thirty-drop doses every four hours, and the application of a lotion of carbonate of potass and laudanum to the joints, the pain and swelling had entirely passed away by the 6th of January. She continued pretty well till the 17th, when the febrile symptoms returned and she complained of sore throat. Next day a bright red rash appeared on the arms and trunk, and the throat was slightly inflamed. The eruption kept well out, and beyond being considerably prostrated, she appeared to be doing well till the 22nd, when she was much more feverish, and complained of acute rheumatic pains in the wrists, knees, and shoulders. The *actea* was again prescribed, and the same lotion was applied to the affected joints, and by the 29th the pain had almost entirely subsided; but on the 2nd of February a friction

sound was discovered over the left lung, and the breathing was panting and hurried. The heart sounds were normal. Croton oil and liniment was applied to the affected side, fomentations were used, and a mixture of vini antimonalis and sweet spirits of nitre was prescribed.

By the 6th of February the breathing had become easier, and, with the exception of a little dulness on percussion, the chest sounds were pretty good, and the pain in the joints had quite left. A tonic was then ordered, and the patient gradually, but very slowly, regained her health and strength. She was dismissed on the 16th of March recovered. I understand that she has never again, up till this date, suffered from rheumatism.

In this case the administration of the tincture of *actea racemosa* was followed by a speedy diminution of pain in the affected joints, and was of decided benefit in allaying the fever and irritability of the patient. It is somewhat difficult to explain how this curious disease should at times assume an epidemic form in some countries, but that it does so is undoubted. During the time this patient was under treatment, scarlet fever prevailed to a considerable extent, but in none of the other cases which came under our observation, was the rheumatic complication present. We may remark, however, that it is by no means rare to find patients who have suffered from fever of any kind, but chiefly from typhus, complaining of severe pains in the muscles and joints during convalescence. But this may, perhaps, be due to hyperæsthesia more than to rheumatism.

CONTRIBUTIONS TO CASES OF CEREBRO-SPINAL DISEASE.

By PATRICK FRASER, M.D.,
PHYSICIAN TO THE LONDON HOSPITAL.

CASE OF PARALYSIS, WITH REMARKABLE SOFTENING OF THE SPINAL MARROW.

Case 1.—J— T—, age 35, a gardener, became an in-patient at the London Hospital; states that, for the first time, he experienced an uneasy sensation in the feet and legs two months ago upon a very cold day, when employed nailing up the branches of a fruit tree to the wall. Since then the weakness, as he calls it, has slowly crept upwards, and he is now in the following condition: imperfect paralysis of the upper extremities, there being complete loss of motion, but sensation is present; perfect paralysis of the lower extremities; the loss of sensation commences at the inferior margin of the ninth rib; angle of mouth drawn to the right side; loss of power in the sphincters of the rectum and bladder.

Treatment.—Under the employment of a spirituous extract of *nux-vomica*, by the 18th of February, twenty-five days after admission, he had recovered the perfect use of the right hand and arm, the recovery beginning at the little finger and going upwards. Upon the 9th the right arm was again paralyzed, and the respiratory muscles in high action. He became comatose upon the 20th, and died in a few hours.

Post-obit examination twenty-four hours after death. Brain perfectly healthy; the theca vertebralis perfectly healthy, and no effusion; the spinal marrow throughout its whole extent, but most especially at the lower cervical and upper lumbar vertebrae, in a state of complete softening; nothing abnormal in any other organ excepting absence of the pericardium.

CASE OF SOFTENING OF THE BRAIN WITHOUT PARALYSIS.

Case 2.—G— M—, aged six years, was admitted into the London Hospital with a slight contusion on the right leg, caused by a kick from a horse; there was also a slight bruise on the forehead. For the first few days he went on well; on the 14th day after admission he became rapidly comatose; had strabismus with dilated pupils; no paralysis. He died upon the nineteenth day after admission.

Post-obit examination forty-eight hours after death.

Body emaciated; within the skull the veins and sinuses gorged with blood; a small quantity of lymph deposited on the surface of the arachnoid; vessels of the pia mater injected; ventricles much distended by serous fluid. The corpus callosum, the septum lucidum, and the fornix were in so softened a state as not to admit of handling. Nothing remarkable in any other organ.

Clinical Remarks.

It is not easy to determine whether the softened state of the chord in the first, and of the brain in the second, case arose from an acute inflammatory action, or from some peculiar disorganising process independent of inflammation.

This is a question of great physiological interest as well as of practical importance, and has been discussed by many eminent men. Copland states that this form of softening "is most frequently the consequence of a form of *subacute* inflammation," and then adds: "At the same time I think it cannot be denied that it sometimes originates in a different way, being preceded by no signs of inflammatory irritation, or attended with inflammatory appearances, and is a simple consequence of diminished or altogether lost vital power, and cohesion of the part affected."

Rostan "admits that inflammation may produce softening; but believes that (more) generally it is a peculiar degeneration of the brain unconnected with inflammation."

Dr. Abercrombie conjectures that there may be two causes, each of which may produce softening: the first is inflammation, and takes place in young people; the second is in consequence of a failure of the circulation depending upon diseases of the arterial system, and this occurs in old people: the latter he compares to "senile gangrene."

Now, these two-sided opinions, and the manner in which all writers quit the subject, show that we have yet much to learn upon this subject. Brown-Séguard and later writers have not added as yet much to our information on this very interesting topic.

In the first case, the patient, during life, presented none of the symptoms which usually accompany inflammatory action, and at the examination after death no traces of inflammation were observed, *with the exception of the softening*. In the second case, I am not inclined to attribute all the mischief to the slight bruise on the forehead. I think that the boy had a brain affection previous to the accident, which latter acted only as a proximate cause.

Although it is known that inflammation may go on to a disorganizing extent without inducing in mass the "dolor," "calor," "rubor," et "tumor" of Cullen, still we expect to find or see some one of the usual effects, some general constitutional disturbance, or some of the marks by which the presence of inflammatory action is usually inferred; otherwise it is not inflammation, according to the ordinary acceptation of the term. The term "sub-acute" inflammation does not remove the difficulty, for "sub-acute" is a conventional term used to explain a grade of inflammation existing where there is depressed vital power; but the symptoms are always in a ratio to the power of the patient, and however low the action may be, it is still inflammation. Not so with softening of the brain or spinal marrow; either may take place in a person of robust health without showing a single symptom of inflammatory action.

In the first case the paralysis of the tongue indicates an affection of the lingual nerve, which leads us to suppose that the brain was becoming implicated; and in the second case the absence of paralysis agrees with an observation of Lallemand, who states that the parts softened in this case—viz., the "corpus callosum," the "septum lucidum," and the "fornix," having no direct communication with the spinal marrow, hence there is no paralysis.

A CASE OF GUNSHOT WOUND OF THE BRAIN UN- ATTENDED BY ANY MARKED SYMPTOMS.

Case 3.—John Fitch, age 25, a soldier, in an attack upon the city of Oporto on the 5th July, 1832, received a musket shot an inch above the ridge, and exactly in the

centre of the frontal bone. A few hours after the injury there were no urgent symptoms, and, as there was a doubt as to whether the ball had penetrated into the substance of the brain, he was merely required to be kept quiet, upon low diet, and to have active saline purgatives. Upon the 7th he was observed to be moping about, avoiding society, and having evidently, although he made no complaint, an intolerance of light.

Ten grains of calomel with two drops of croton oil were given immediately, which shortly produced a copious evacuation. On the morning of the 8th he was found comatose, pupils dilated, pulse full and regular. The trephine was used, and several broken portions of the external table removed: on further examination a piece of bone was felt deeply indented in the brain; this, a portion of the internal table, was removed with some difficulty, upon which at least a drachm of pus escaped; several convulsive respiratory acts immediately followed, but no further improvement took place, and he expired four hours after the operation.

Post-obit examination a few hours after death.—Upon raising the calvarium, an opening, corresponding with the external wound, was observed through the membranes leading to a small abscess exactly under the seat of the depressed bone, and from this abscess a track was traced leading into the right ventricle. Both ventricles were filled with purulent matter. Between the dura mater and arachnoid, patches of pus were observed, most abundant at the base of the brain and around the medulla oblongata. The arachnoid was thickened in many places. No bullet, after a close search, was found.

The above case is an instance, among others recorded, of the vast extent to which disorganisation of the brain may proceed without inducing either apoplexy or paralysis, &c., or any very marked brain symptoms.

Hospital Reports.

SIR PATRICK DUN'S HOSPITAL.

Reported by Dr. BELCHER.

BELL'S PARALYSIS OF THE PORTIO DURA.

I AM indebted to the kindness of Professor Aquilla Smith for the opportunity of reporting the following case, now under his care. He has treated it with a view to show the special therapeutic action of a single remedy. At his invitation I myself have seen the case; and I am further indebted to the kindness of his son, Dr. Walter Smith, from whose note-book I have in great part compiled the following details:—

Samuel Davidson, ætat. 25, healthy, but inclined to take colds, engaged at the Model Farm, Glasnevin, was admitted into Sir Patrick Dun's Hospital on Saturday, 17th February, 1866, labouring under paralysis of the portio dura of the left side. About ten or twelve days before admission he had undergone a long day's work, and for four or five hours was exposed to a cold dry wind, particularly on the left side of his body. This does not appear to have affected him at once, though he noticed a chill in his face at the time; but next morning he was surprised to find that what he drank ran out of the left corner of his mouth, and that in masticating his food a great portion remained in his left cheek. However, he attributed all this to cold, and sought no advice for eight days, when he took to his bed, and, by advice of his medical attendant, put a small blister on the lower part of the left cheek, without any benefit being derived from it.

Appearance on admission.—There is the usual difference between the expression at the two sides of the face when the muscles are attempted to be brought into action, but not otherwise.

The mouth is drawn to the right side. The tongue is protruded to the same side; but there is neither numb-

ness nor loss of taste. When he shuts his mouth and puffs out his cheek, the left cheek is more protuberant than the right. His speech is slightly affected. With regard to the liquids, especially the letter "M," he himself says that this difficulty was more marked a few days ago, particularly as to the word "improvement." As is usual, he can neither whistle, purse up his lips, nor spit out; neither can he raise transverse or vertical wrinkles on the forehead of the affected side. He also manifests inability to complete closure of the left eyelids. The sensibility to touch, when pinched, was found unimpaired.

February 20th: *Treatment.*—Local electrification with the induced current resorted to. Wet sponges, and also pointed metallic conductors, severally employed. The sensibility was found to be a little impaired; but there was no pain felt. The orbicularis palpebrarum muscle readily responded to the electric stimulus, and, after the application of the remedy, he was able to cover the eyeball with the lids, though previously unable to do so.

21st: He can now cause the lids to meet over the eyeball, and thinks there is some improvement in eating.

Treatment.—Electricity again applied by wet sponges, and this time also with marked effect, especially on the buccinator, orbicularis palpebrarum, corrugator, and occipito-frontalis muscles.

22nd: He now closes the lids perfectly; can eat much better; and can wrinkle the left side of the forehead a little.

23rd: Marked improvement in the power of wrinkling the forehead; he now feels twitchings in the orbicularis palpebrarum.

24th: Improving in every way.

26th: Steady improvement; he can now move the mouth a little towards the affected side.

28th: Scarcely any distortion visible; when the muscles are brought into action he can almost whistle; the natural wrinkles are reappearing on the left side of the forehead.

March 2nd: The transverse wrinkles on the forehead are now well marked; the buccinator muscle is notably recovering its power. It is expected that this man will be discharged from hospital in a few days; and Dr. Smith looks on it as a striking instance of the curative effect of electricity independently of any other means.

CASE OF PHOSPHATIC CALCULUS IN THE MALE BLADDER, WITH A NUCLEUS OF BONE (PROBABLY A SEQUESTRUM DETACHED FROM THE INNOMINATE BONE).

By HENRY THOMPSON, F.R.C.S.,

SURGEON EXTRAORDINARY TO H.M. THE KING OF THE BELGIANS,
SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

A MAN aged 40 was sent to the care of Mr. Thompson, at University College Hospital, by Dr. R. Uvedale West, of Alford, Lincolnshire, in June, 1865, for a urinary affection of two years' standing. On examination, a stricture near the orifice of the urethra and a stone in the bladder were found. On June 27th the stricture was divided by the bistoury, and the first crushing was performed on that day. All going on well, the stone was again crushed on the 30th. On this occasion the *débris* withdrawn in the jaws of the lithotrite was remarked at the time to be unusual in character, but was not then minutely examined. Four days after this, retention was caused by a fragment impacted in the urethra; this was withdrawn by means of the forceps, and it was at once seen to be a fragment of bone. Other small pieces fol-

lowed, and the patient went out cured on the 15th July. He remains perfectly well at the present time.

It was not until after the appearance of the bone that a minute history of the case was taken. The following circumstances were then elicited:—The patient had had severe pain in the right hip seventeen years ago, and was lame for more than a year. Then an abscess broke externally, the cicatrix of which, among many others, is seen about the joint. Another attack took place three or four years after, from which several abscesses and much pain and lameness resulted. Two years ago another attack laid him him up for several weeks, but no external abscess resulted. When recovering from this, he became the subject of some pain and frequency in micturition; and finally the ordinary symptoms of stone appeared, and continued up to the time of his admission.

The author made reference to some analogous but not precisely similar cases, no example of the latter having been at present discovered.

The conclusion which he arrived at after full investigation was, that the origin of the calculous formation in this case was the existence of disease in a part of the os innominatum, resulting in necrosis of a small portion; and that this portion ultimately exfoliated and detached itself, to be extruded, not externally by the surface of the body—not by means of abscess which should follow the usual course along the tracks of muscles or vessels, but by one which communicated directly with the bladder, so that the sequestrum made its way into that cavity, and formed the nucleus of the phosphatic stone for which the patient was subsequently successfully operated on by lithotripsy.

CASE OF LITHOTOMY; MULBERRY CALCULUS WEIGHING EIGHT OUNCES AND A QUARTER; DEATH.

By JOSEPH ALLEN, M.R.C.S., Norwich.

(Communicated by WILLIAM LAWRENCE, Esq., F.R.S.)

The author was summoned to the Rev. T. C.—, a thin spare man, of nervous temperament, aged 56 years, on Nov. 16, 1864, and found him suffering great pain and irritability of the bladder. He was a married man, of temperate habits. Had been married seventeen years and a half, and had three children growing up. A few days previously he had caught cold whilst performing the funeral service at the cemetery, and had suffered considerable pain in the body since, accompanied with frequent and painful micturition. He had tried several remedies without avail. Opiates and other anodynes, &c., were prescribed, but with only temporary relief. His history was as follows:—

He was born in Surrey, and from his boyhood was fond of exercise, running, jumping, &c., but frequently suffered great pain afterwards, and often passed blood in his urine; this he concealed lest he should be debarred from such pursuits. As a young man, hunting had the same effect, but his love for the sport was too great to allow him to give it up. He resided at Calais for eleven years, and enjoyed good health all the time. He afterwards spent seven years in London. He was ill for about three weeks shortly before leaving London with inflammation of the bladder, according to his account. Has resided in Norwich about five years. His health generally has been good, dyspepsia being his chief ailment, which a little carbonate of soda mostly removed. He confessed, however, to great irritability of his bladder for some years past, having been compelled whilst in London to micturate every two hours, and latterly had been unable to retain the urine more than one hour, so that he was compelled to time his visits in the parish accordingly.

On Dec. 5th, 1864, he was sounded by the author in the presence of Dr. Eade, having previously refused to permit it through false delicacy. The sound, immediately on entering the bladder, came in contact with a large and hard stone. The urine contained lithic acid in considerable quantity, also pus-globules.

It was determined to perform lithotomy, which was ac-

cordingly done on the 8th of December. The ordinary lateral incision was made, and the stone readily seized with the forceps. On attempting to extract it, however, it was found to be one of no ordinary size. Larger forceps were then introduced, and a firm grasp obtained, but without avail. In order, therefore, to avoid laceration of the parts as much as possible, the fibres of fascia on either side were carefully cut with a blunt-pointed bistoury by Mr. Cadge, traction being made on the stone at the same time. The perineum was enormously distended during the extraction of the stone. After a short time a mulberry calculus, weighing eight ounces and a quarter, was removed. There was scarcely any hæmorrhage, and very little laceration of the parts. The patient was remarkably well after the operation, and for a time progressed most favourably, the wound presenting a healthy appearance, and gradually closing. He was able to retain his urine in the bladder for three hours, a thing he had never done before for years. After a time, however, his spirits began to flag, and he became fidgety and impatient; and although well supplied with nourishment and stimulants from the first, he gradually became weaker, and at last sank from exhaustion on Jan. 20th, 1865, six weeks after the operation.

Mr. HOLMES COOTE said the case related by Mr. Henry Thompson was worthy of great consideration. There was one point, however, on which information was desirable—viz., as to the microscopic structure of the nucleus of the calculus. This would remove the possibility of doubt as to its being bone. Mr. Thompson had said that there was no specimen in the museum of St. Bartholomew's Hospital of a calculus with a nucleus of bone. He (Mr. Coote) remembered a case in which Mr. Lawrence had removed a calculus from the bladder of a woman. In this instance the bone was that of a sheep, and, of course, had been introduced from without. He could scarcely understand how the piece of bone in Mr. Henry Thompson's patient's case could have got into the bladder in the way suggested by the author, with so little irritation. Mr. Coote then spoke in eulogistic terms of the operation in the case brought forward by Mr. Allen. It was probably the largest oxalate of lime calculus that had been removed by the lateral operation of lithotomy. Mr. Coote also remarked that although Mr. Allen had not alluded to the fact, the history of the case clearly showed that the patient did not die of the mere operation. That was skillfully performed, and reflected the greatest credit on the operator. Had there been an autopsy, he (Mr. Coote) had no doubt it would have revealed other diseases as the cause of death. The coma pointed to renal disease. Mr. Coote concluded by saying that the operator was worthy of great praise.

Mr. ERICHSEN agreed in the main with Mr. Coote. He thought it a matter of great importance to distinguish cases of stones in the male and female bladder as regards the source of their nuclei. We know, he said, that in the female bladder the nuclei may be most various substances introduced from without; but a piece of bone was scarcely likely to be introduced by the male urethra. He agreed with Mr. Thompson that it most probably came from the pelvic bone in his patient's case. With reference to the second case, Mr. Erichsen said the stone was very large, although he was not prepared to say that it was the largest oxalate of lime calculus which had been removed by lithotomy. The case was of importance as regards the question of removing a stone through the prostate. In cases in which we hear of such great difficulty in removal, he could not help thinking the gland had been divided beyond its limits. The case introduced the question of small and large incisions in the prostate. No doubt, in Mr. Allen's case the best method of getting the stone out was adopted; but he could not think it could have passed through the lateral lobe without extending beyond its limits. Mr. Erichsen concluded his remarks by expressing his opinion that death was caused by renal disease, and not by the operation.

Mr. CHARLES HAWKINS had no difficulty in coming to

the same conclusion as Mr. Thompson had; he had very little doubt that a foreign body could make its way into the bladder from other parts of the body. He referred to a case in the practice of Sir Benjamin Brodie, in which the nucleus of a calculus removed from the bladder of a female consisted of a small portion of bone and two imperfectly-formed teeth, and to another case in which large quantities of hair, covered with calcareous matter, had been passed. Mr. Hawkins believed that these foreign bodies had come from tumours connected with the ovaries. Mr. Hawkins then referred to cases in which faecal matter had found its way into the bladder, and gave brief particulars of a case of calculus in the bladder, the nucleus of which calculus was some vegetable substance derived, he believed, from fœces. In this case Mr. Hawkins had removed the calculus by lithotripsy with success.

Mr. SPENCER WELLS said that, without in the smallest degree criticising the mode in which the very large oxalate of lime calculus had been removed—feeling, indeed, that the operation was a very creditable one to the surgeons concerned—he still wished to ask the author of the paper, simply as a guide to future practice in a similar case, whether it would not give a patient a better chance of recovery, in a case where a stone was known or believed to be unusually large, either to perform the high operation, or to be prepared with some powerful crushing apparatus, by which, after the bladder had been laid open, the stone might be broken and removed in fragments? Either of these plans would seem to be less hazardous than the forcible dilatation or the large incisions necessary for the removal of a very large unbroken stone by the lateral or bi-lateral perineal operation. With regard to the curious substances found as the nucleus of calculi, he (Mr. Wells) might add that he had recently removed a phosphatic calculus from the bladder of a patient who had undergone an operation for vesico-vaginal fistula, and a loop of silver wire which had got into the bladder had formed the nucleus of the calculus.

Mr. HENRY LEE said that Mr. Erichsen implied in his remarks that the best plan to deal with large stones was to cut them out, rather than to tear them out. In this opinion he (Mr. Lee) concurred. Mr. Lee then referred to a case of lithotomy of his own at St. George's for the removal of a very large stone. In this instance he cut, no doubt, beyond the limits of the prostate, and the result of the case showed that the practice did not always lead to bad results. The calculus was phosphatic, and weighed four ounces and a quarter, and there was another stone in the bladder, extracted at the same time, which weighed a quarter of an ounce.

Mr. PROPERT said that twenty-five years ago he had under his care a young gentleman who had a knack of driving things up his urethra. At last he passed up a long piece of sealing-wax. The specimen of wax afterwards removed from the bladder would be found in the museum of St. George's Hospital. Sir B. Brodie, who was consulted, could not discover any foreign body in the bladder, and the patient went to India. After remaining in India some time, symptoms of stone in the bladder came on, and the patient came home for operation. Sir B. Brodie operated, and removed a calculus, the nucleus of which was a piece of sealing-wax. The patient recovered, and went out again to India, when, unfortunately, he was drowned.

Mr. MOORE had had under his care at the Middlesex Hospital a patient above thirty years of age who had a similar strange fancy for passing foreign bodies into his urethra. He one day introduced a piece of sealing-wax. He afterwards had mucous and phosphatic urine, and suffered so much that lithotomy was performed. The piece of sealing-wax was removed and placed in the museum. The fragment was bent on itself, and had the ordinary flattened oval shape of a calculus. It was creased and compressed, as if it had been squeezed into its form by the contractions of the bladder. As regards the source of the nucleus in Mr. Henry Thompson's patient's case, he

could not conceive that there could be any great difficulty in the way of the belief that it had been detached from the pelvic bone, and had made its way into the bladder. He did not think the passage of purulent matter from an abscess into the bladder was likely to produce any injurious consequences, and he referred to cases which served to show that the action of urine on abscesses communicating with the bladder did not affect them injuriously; on the contrary, the stimulating action of the urine appeared to produce salutary effects.

In reply to a remark by Mr. Holmes Coote, Mr. MOORE said that he did not mean that pelvic abscesses were not serious, but that the mere entering of matter from an abscess into the bladder was not serious.

Mr. SOLLY agreed with the other speakers as to the great probability that the bone was an exfoliation from the ischium, and he agreed with Mr. Moore that an abscess might empty into the bladder without producing any striking disturbances. In illustration, he referred to the case of a patient lately under his care in St. Thomas's Hospital, who had paralysis of the legs consequent on disease of the spine, and who had quite recovered, after having passed much purulent matter in the urine. The case related by Mr. Allen introduced the question whether it would not be better to crush a stone when it was found to be so large, as in that case, before attempting to extract it. On one occasion he had prepared beforehand an instrument for this purpose, but it turned out that the stone was not so large as had been expected. He thought the surgeon ought to be prepared with a crushing apparatus in order to break up the stone when it was very large.

Mr. CHARLES HAWKINS described an instrument—a pair of strong forceps with large teeth—made by the direction of Sir B. Brodie for use in a case of lithotomy, but the instrument was not required, as the stone did not prove to be as large as was expected.

Mr. SOLLY said the instrument he had had made was like the one spoken of by Mr. Hawkins.

Mr. THOMPSON thought the evidence all but complete that the bone had its origin in the body of the patient himself. Still he should be glad to submit the fragment to microscopical analysis to determine accurately that point. He was, of course, quite alive to the various sources of error on this point. It was not long since he performed lithotomy for the removal of sealing-wax introduced by a patient into his own bladder, and he had more recently removed a hair-pin from the bladder of a male, who had so introduced it. With reference to the important and interesting case of Mr. Allen, there were two points well worthy to be considered with regard to it. First, was it possible to crush that stone through the wound, and so withdraw the fragments, instead of enlarging it? He had seen no instrument which he thought capable of crushing a large oxalate of lime stone, certainly none by way of compression. He had cut a gentleman last summer and removed an oxalate of lime stone weighing $3\frac{1}{4}$ oz. Before withdrawing it he had applied forceps of great strength, and with a powerful screw in their handles, and he had screwed the handles together, bending the iron, but no impression was made on the stone. The best method he had seen was one employed by Civiale, who, after trying it and perfecting it on twelve or thirteen cases, had just introduced it to the Academy of Medicine at Paris. Mr. Thompson had seen all those calculi so crushed and removed, and considered it a very valuable instrument. It was accomplished by means of perforation by a drill, which split up the stone. Secondly, there was the question of the high operation for such a stone. Could it have been ascertained to be so large—and no doubt such information it was possible to attain—he believed the high operation would have been preferable. The bladder was nearer to the surface above the pubes in a thin individual such as this patient was; less important parts were in the way than in the perineum, and the depth of this region, which is exceedingly embarrassing with so large and spherical a

stone, was avoided by that procedure. Altogether it was well worthy of consideration whether such stones should not be removed by the high or supra-pubic rather than by the lateral operation. He inclined to the belief that the former was preferable for these cases.

Mr. JOSEPH ALLEN explained how it happened that leave to make a post-mortem could not be obtained. Although the post-mortem might have revealed renal disease, there had been no positive evidence of it during life. The patient seemed to sink from nervous depression. As regards the prostate, as no post-mortem examination had been obtained, it was impossible to speak positively. He was glad to find that Mr. Henry Thompson, in his reply, had relieved him (Mr. Allen) of the necessity of replying to several questions which had been put to him. Mr. Allen said that the largest stone—not an oxalate—which had been removed in Norwich had been removed by the lateral operation, and the patient recovered. For this reason he did not think of the high operation; moreover, it was not easy to ascertain the size of a stone before the operation.

NEW ARTIFICIAL ARM.

After the meeting, Mr. UREN, of Cornwall, exhibited an artificial arm which he had invented, and which had been made by Messrs. Weiss and Son. This seems to be an improvement on the artificial arm in ordinary use. Movement of the elbow, opening and closing of the fingers, are maintained by the movement of the stump of the upper arm acting on some cords which are connected to the arm and to straps across the trunk. The man who wore it said it was comfortable, and that it was of considerable use to him.

SURGICAL SOCIETY OF IRELAND.

FEB. 16, 1866.

Dr. WILMOT, President of the College, in the Chair.

TUMOUR OF SCALP.

DR. STAPLETON said that as there was a discussion on a former evening, relative to tumours of the scalp, he had brought with him a drawing of a case in which he had removed such a tumour. The contents of the tumour were like fluid honey, with particles resembling wax floating throughout. This tumour had existed from birth, and had grown under the pericranium and indented the skull. He had a great deal of trouble in removing it, because of the adhesion to the skin and the pericranium. He also exhibited the cyst of another tumour, which he had removed from a boy 14 years of age, about the size of a large marble. This, also, had existed from the time of birth. It was filled with the same sort of fluid, with the exception of being somewhat denser. One was clearly congenital, and in the other case the man, who was about 35 years of age, said he had had it as long as he could remember.

Dr. STAPLETON likewise made some observations on the case of Clarke, who was recently shot on the bank of the Canal.

SPECIMEN OF PELVIC VISCERA.

Dr. MINCHIN exhibited the pelvic viscera of a patient who had died of peritonitis caused by a ruptured ovary. She came into hospital with the following symptoms:—She was a young woman, 30 years of age, and had for three weeks previously been gradually losing health and strength. She had low fever, loss of appetite, loss of sleep, diarrhoea, and extreme debility. On the night she was admitted it was found she had retention of urine for fifteen hours. The resident drew off the contents of the bladder, and administered an opiate, and he (Dr. Minchin) saw her next morning. She then had retention of urine; there was great prostration of strength, the countenance was sunken, and the skin sallow, almost jaundiced in appearance, but of a more brownish appearance than jaundice; there was total loss of appetite, foul

tongue, and very great diarrhoea during the whole night. On examining the abdomen in a cursory way, no pain was experienced; this part was not tumid, nor was it sunken, and there was a considerable layer of fat on the walls of the abdomen. After drawing off the urine, and passing his hand over the abdomen, a tumour was found in the right iliac region. On the left side and across the middle of the abdomen pressure was borne without any complaint. The difficulty, then, was to ascertain the nature of the tumour in the right iliac region. The woman's menstruation was regular, and had taken place nine days previously. There was no pain in the uterus or bladder. There, therefore, did not appear to be any urgent necessity for an examination in that quarter, particularly as the patient was weak and suffering from diarrhoea. The diarrhoea was altogether beyond control; everything was done to suppress it, but without effect. The bladder remained torpid, and had to be evacuated twice a day. The appetite was gone, and it was with difficulty they could induce her to take anything; but they succeeded in administering wine and restoratives in small quantities. On the third day of her being in hospital, on removing the urine from the bladder, he found there was some prominence, and on passing the finger into the vagina, he discovered that the entire pelvis was filled with a large tumour. In the debilitated state in which the patient was, he could not make a better examination. Touching the tumour with the finger gave no pain, nor did the woman know that there was anything wrong there. Next morning he found that the patient had taken sudden symptoms of peritonitis the night before, and she died rapidly of this disease in an intense form. He took out all the pelvic viscera. The bladder was perfectly healthy, and the uterus also was sound. The tumour was a large fibrous polypus, and there was no strangulation in the neck of the uterus. How the tumour came to be turned over to the right iliac region he could not say, except the existence of an abscess might have acted in pressing it over. The left iliac region was filled up with an exceedingly dark purulent matter, which escaped through a small hole, and no doubt was the origin of the peritonitis which occurred. The peritonitis was circumscribed, but in her debilitated state it required very little to destroy life. The ovary presented a sanguino-purulent cyst, which had burst; the left ovary was healthy. The finger could be passed with great ease round the inside of the neck of the uterus, notwithstanding the existence of this large polypus. The reason he brought the case forward was to show how a tumour of this kind could exist for a long time without any symptoms that would attract attention. The woman said she had never received any treatment from a medical man, and was not aware that the tumour was in the pelvis.

THE SUPERIOR PULMONARY VEINS OF THE RIGHT SIDE OPENING INTO THE SUPERIOR VENA CAVA.

By ALEXANDER MACALISTER,

DEMONSTRATOR OF ANATOMY, ROYAL COLLEGE OF SURGEONS, IRELAND.

A few days since Mr. Dwyer, one of our pupils in the College of Surgeons Dissecting-room, called my attention to a peculiar arrangement of the vessels in the root of the right lung of a female subject, which was not referable to any of the usual types.

On examination, the abnormal vessel proved to be the superior right pulmonary vein, which was situated above the other parts in the root of the lung, and arose by several tributaries which passed out of the pulmonary substance, and, uniting, formed a single vessel that poured its blood into the superior vena in the same plane as the vena azygos, but anterior to that vessel. There was no trace of a valvular apparatus at the site of the communication, and the vessel was much smaller than its inferior companion.

Nothing was known of the life history of this individual, but probably the anomaly did not give rise to any marked symptoms. The embryological history of this anomaly is

rather obscure, but most probably it arose from an error in development by which the right upper pulmonary vein communicated with the duct of Cuvier on that side instead of being posterior to it, as it should have been. There is, however, I believe, no normal connexion primarily between these vessels in their embryonic condition.

Other forms of communications between the arterial and venous trunks near the heart are well known; but the class of which this is a representative is among the rarest of such connexions. I have seen but one other example of this nature; but although it was even more singular than the present, yet I regret the specimen was inadvertently destroyed before I could preserve it. In it the superior pulmonary vein of the right side, after entering the pericardium, pierced the auricular septum, and bifurcated, or at least opened, by one small opening into the left auricle, and by a large oblique orifice into the right auricle. In this instance, which was clearly the result of imperfect septal development, the same condition would have occurred as in the present instance—viz., a mixture of arterial with the venous blood in the right side of the heart. Whether this might not exercise some effect in the development or condition of the lungs would be an interesting inquiry, and one which, in neither of these instances, could I elucidate. The late Dr. Mayne, I believe, described a variety of a somewhat similar nature as the last mentioned.

NON-DEVELOPMENT OF THE GALL-BLADDER.

In the abdomen of a thin male subject I found that there was no appearance of a gall-bladder in its usual position, and on careful examination I discovered that only a small rudiment of such existed. The vesical fissure in the liver is obvious, but bridged over with peritoneum, and the only trace of this sac existed as an extremely minute appendix to the hepatic duct, and lay between the laminae of the gastro-hepatic omentum.

In man this anomaly is decidedly rare, although among mammalia, many of the ruminantia and pachyderms are destitute of this appendix, as the cervidae: although present in the ox, sheep, and others.

HOLT'S TREATMENT OF STRICTURE OF THE URETHRA.

Dr. FLEMING wished to bring under the notice of the Society a case that came before him that morning at the Richmond Hospital. The subject was a book-binder, aged 25. He was a patient in the Adelaide Hospital in 1862, labouring under the symptoms of organic stricture of the urethra. He was under the treatment of Mr. Barton. At the time of admission the stricture was of the class that it would hardly admit No. 1 or 2 catheter or bougie, and under Mr. Barton's treatment the case improved, so that after the time the man left hospital an instrument up to eight or ten, and conical in shape, could be introduced. In November in the same year the man went to the Meath Hospital, and was under the care of Dr. Macnamara. The stricture was then very tight, but by degrees Dr. Macnamara was able to get in Mr. Holt's apparatus, and with it he dilated the stricture. He afterwards introduced catheter No. 11. This he introduced upon a second occasion, and he was kind enough to ask him (Dr. Fleming) to pass the catheter. He did so, and succeeded in passing either Nos. 10 or 12 in the erect posture without the slightest interruption. He was at the Richmond Hospital this morning complaining, not of uneasiness in the urethra, but in the vicinity of the urethra, fancying he had piles, but none were visible. He said he was free from any urinary symptoms; that he did not pass water more frequently than natural, and that there had been no catheter passed since 1862. He (Dr. Fleming) introduced the full-sized instrument that day with the most perfect facility; there was not the slightest interruption.

Dr. STAPLETON—Do you know any case in which Holt's plan has not succeeded?

Dr. FLEMING said he had adopted Mr. Holt's plan in

not a few cases, and in those cases which were the most unmanageable of all, stricture of the orifice of the urethra, resulting from chancre, and where, also, there was generally a second stricture in the vicinity of the bulb.

Dr. STAPLETON—With respect to stricture of the orifice of the urethra, he had a case of that sort in a boy in Jervis-street Hospital who had an ulcer that eat round the orifice of the urethra. He had the greatest difficulty in finding the orifice with a probe. He introduced Holt's instrument and burst it. There was some bleeding. He was proud of the case, and showed it as a fine specimen, but some time afterwards he found it contracted to what it was before.

Dr. MACNAMARA distinctly remembered the case. It was precisely what Dr. Fleming had stated. From his experience in this method of treating stricture, he was far from saying that every case had been invariably successful; but he would say that the result of the majority of those cases had been most gratifying. In every case that had turned out successful there had been a little bleeding, and in those cases in which there had not been a drop of blood he expected an unfavourable result. He liked to see a few drops of blood appear after the operation, and on the next morning the shirt notably stained. Whenever that had taken place he had always found a satisfactory result, but in those cases which had been perfectly bloodless he anticipated that the operation would prove a failure. He firmly believed in that form of elastic stricture which, no matter what the form of operation employed, would recur again and again.

Dr. DARBY said that no matter what plan of treatment was adopted some cases would relapse, and every man who had treated stricture must have experienced cases of that kind. If the immediate plan was as successful as the more dilatory, and equally safe, he would say it was the best from the fact of its being immediate. He had hitherto had no opportunity of seeing the immediate plan tried, but he confessed he was rather prejudiced against it. He remembered when Stafford's instrument was in daily use, and when treatment by the caustic bougie was also practised, and surgeons differed much with one another as to the efficacy of the respective modes of treatment. He believed that by increasing the size of the bougie he had cured many cases without the sign of a relapse. He had gone on gradually dilating until he had reached the size of 15 or 16, and he thought if they stopped at No. 10 there was danger of a relapse taking place.

Dr. FLEMING said he did not stand up as the warm advocate of Mr. Holt's treatment, but he thought it right to bring the present case forward as one in which the immediate plan seemed to have been attended with very favourable results.

INTERNAL ABDOMINAL STRANGULATION AND THE OMPHALO-MESENTERIC VESSELS—THE LATE PROFESSOR HARRISON'S VIEWS.

Mr. B. W. RICHARDSON stated that he was indebted to his friend Dr. Sinclair, the accomplished Professor of Midwifery in the University of Dublin, for the living specimens of young salmon in the jar which he held in his hand. They were about sixteen days old, and still possessed the umbilical vesicle, which is yet comparatively of large size. It is scarcely necessary to remark that as fishes leave the egg before being as fully matured as either the chick or mammals are when born, they have consequently the umbilical vesicle at birth, which organ, in addition to its other uses, acts as a temporary respiratory apparatus until the gills are fully perfected. As then the umbilical vesicle acts as a temporary lung in fishes, these animals are not provided with an allantois, which performs this function in both mammals and birds. He (Mr. Richardson) would place the salmon in water in cells under the microscope, when the members could view the circulation in the omphalo-mesenteric vessels in the umbilical vesicle. In their present state of development the move-

ment of the circulation of the blood can only be clearly seen in the umbilical vesicle; but, a few days, ago when the specimens were more diaphanous than they are now, the blood could be distinctly seen circulating along the whole spine, the diff rent course of the arterial and venous blood being most manifest.

These specimens are not only of physiological, but are also of surgical, interest, for, the omphalo-mesenteric vessels afforded to the late Professor Harrison the *matériel* for a very ingenious theory regarding internal abdominal strangulation. Several years ago while that most distinguished member of this College was making some observations at the Dublin Pathological Society regarding a specimen of internal strangulation, remarked, that he considered that the bands which sometimes cause internal abdominal strangulation, may be either the result of inflammatory action, or may consist of some original natural structure belonging to the period of fetal life. In Dr. Harrison's case, a cord extended from what he calls the end of the urachus, back towards the mesentery, into which it was inserted. This formed a noose in which a portion of intestine was engaged and strangulated, causing peritonitis and rapid death. He (Dr. Harrison) observed, "that from the situation, appearance, and attachments of the band, it was plain that it could be nothing but the urachus, with the remains of the omphalo-mesenteric vessels. In the chick," he further remarked, "the vessels which form the *area vasculosa*, on the surface of the yolk-bag, gradually unite and form two vessels, which, as the animal grows, run towards the mesentery, in order to transmit the blood to the heart. In the human subject," says he, "there is an organ analogous to the yolk-bag of the chick—namely, the umbilical vesicle, which disappears about the sixth week of fetal life, and the use of which appears to be the same as that of the yolk-bag. As the child becomes more advanced, the umbilical vesicle is carried into the abdomen and becomes gradually obliterated; but its vessels can be still seen passing in towards the mesentery." Dr. Harrison thought "it was not unreasonable to infer, that what occurred in the lower animals occurred also in man; and as the fetus advanced in growth and the bladder descended into the pelvis, the omphalo-mesenteric vessels would be seen running from the top of the bladder towards the mesentery. In the more advanced period of fetal life, these omphalo-mesenteric vessels, being no longer of any use, wither and disappear; but they do not always do so, and sometimes a rudiment remains, forming a cord which extends from the top of the bladder to the mesentery. From this view of the case he (Dr. Harrison) thought the strangulation was produced by the remains of the omphalo-mesenteric vessels."

Notwithstanding the ingenuity of Dr. Harrison's view regarding the pathology of his case, it appears to me to be hardly tenable. More particularly as his description of the omphalo-mesenteric vessels is not in accordance with our present embryological knowledge. Strictly speaking, the name omphalo-mesenteric is applied to two arteries and two veins which emerge from the sides of the fetus and convey the blood to and from the *area-vasculosa*. The two arteries are given off by the fetal aorta just after the two vertebrae unite to form it. The two veins open into the lower extremity of the heart. These are the omphalo-mesenteric vessels, and are for carrying on the circulation in the umbilical vesicle, the mesentery, and the intestine. As development progresses, the two omphalo-mesenteric arteries and veins are replaced by corresponding single trunks. Now, the term omphalo-mesenteric is usually only applied to those vessels which ramify in the umbilical vesicle, mesentery, and intestine, whereas Harrison's description is more in accordance with the anatomy of the umbilical vessels themselves, and which are contained in the allantois—a structure, by-the-by, which Dr. Harrison did not allude to at all. This structure is gradually protruded from the lower end of the intestine, bringing with it two arteries and two veins.

These are the umbilical vessels. The two arteries are given off by branches of the abdominal aorta, and the veins open into the mesenteric veins, and through these channels their blood reaches the heart. One of the umbilical veins eventually disappears, and as additional labour is thrown upon the other, it enlarges in calibre. As I have already mentioned, the allantois is partly a respiratory organ, and is the medium by which decarbonized blood is obtained for the fetus. It is quite evident that Harrison's account can only be applied to the umbilical, and not to the omphalo-mesenteric vessels, and therefore it appears to me that the strangulation in his case could scarcely have been caused by obliterated omphalo-mesenteric arteries or veins.

(At the conclusion of Mr. Richardson's observations the members viewed the circulation in the umbilical vesicles, the object-glass used for the demonstration being a two-inch, by C. Baker of London.)

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, IRELAND.

MARCH 21st, 1866.

Dr. BEATTY, President of the College, in the Chair.

Dr. WM. MOORE read the details of some cases of PARALYSIS OF SYPHILITIC ORIGIN.

The first case was one of syphilis followed by secondary symptoms and paraplegia, which occurred in a young man, aged 28.

In the second case syphilis was followed by secondary eruptions, *rupia*, and hemiplegia with occasional epileptiform attacks, followed by unconsciousness.

In the third case, that of a female who contracted syphilis, epileptiform attacks were followed by hemiplegia.

In the fourth case, that of a man aged about 45, repeated syphilitic contractions were followed by secondary eruptions, by iritis, and, finally, by imperfect vision, progressive paralysis, and all the symptoms described as incidental to progressive motor ataxy. In these cases anti-syphilitic remedies were adopted, and with success.

Dr. Moore's paper, which was of considerable length, and entered into minute details, became the subject of a discussion in which several members took part.

Dr. BELCHER then read a paper entitled REMARKS ON DIPHTHERIA, CHIEFLY WITH REFERENCE TO ITS CONTAGIOUS, EPIDEMIC, AND FATAL CHARACTER; AND TO ITS SUPPOSED CONNEXION WITH THE CATTLE PLAGUE, AND WITH A CERTAIN STATE OF THE WEATHER, FOUNDED ON THE DETAILS OF SEVERAL RECENT CASES.

In this paper, which, like the preceding, was one of considerable length, Dr. Belcher gave a record of about thirty cases of diphtheria, or of diseases allied thereto, which he had recently met with in private practice. He then proceeded to discuss the supposed cause or causes of diphtheria, its contagious and fatal character, the modes of death in that disease, the frequent occurrence of sudden death during convalescence from it, and its tendency to attack members of the same family, though separated by long distances from each other. The propriety of tracheotomy or laryngotomy was also debated, and reference was made to the descriptions of Huxham, Fothergill, Ruddy, and others, with regard to its supposed identity with the English epidemic of 1748. Its supposed connexion with the cattle plague, and with a certain state of the weather, were also discussed.

At its conclusion, the President said that the discussion on it should be reserved to the next meeting of the Society, after which he declared the proceedings adjourned.

Reviews.

DR. NELIGAN'S PRACTICAL TREATISE ON DISEASES OF THE SKIN. Second Edition. By T. W. BELCHER, M.A., M.D. Pp. 526. Dublin: Fannin and Co. London: Longman. 1866.

STANDARD works, which have been prepared with care by writers specially qualified for the task, should not, on the decease of their writers, become disused. The very admirable works of the late Dr. Neligan above all deserve such preservation, and the enterprising publishers who originally issued them have accordingly secured the most competent editors possible for the purpose. We have had occasion to bestow very great praise on the way in which Prof. Macnamara produced a new edition of the older and larger work of Dr. Neligan, and the present edition of the "Treatise on Skin Diseases," by Dr. Belcher, is worthy of equal commendation. The editor's additions are numerous, and especially with regard to classifications, derivations, definitions, and bibliographical references, very great erudition is displayed. Among new subjects are the eruptive fevers, and a brief but useful account of them is given. With regard to a probable explanation of the nature of measles we make the following interesting quotation:—

"In the *American Journal of Medical Sciences*, July, 1862, Dr. Salisbury of Newark, Ohio, describes a form of *camp measles*, which he attributes to sleeping on mouldy straw. His observations are chiefly to the effect that the influence of the fungi of wheat straw on the human system is, in fact, a poison generated by the mouldy straw, and giving rise to a disease identical with measles. In the October number of the same journal (1862) Dr. Salisbury treats of the prophylactic power which the inoculation of straw fungi exercises in those exposed to the contagion of measles. In the *Dublin Quarterly Journal* for February, 1863, Dr. Henry Kennedy of this city gives a very remarkable case in point, in which the patient was poisoned by having some flaxseed meal suddenly thrown into the eyes and throat. He also remarks that Dr. Kidd of this city made some flaxseed meal mouldy, and then, by the aid of the microscope, detected in it fungi 'very like, if not identical with, some of those figured in the plate of Dr. Salisbury.'"

The description of small-pox, we must confess, strikes us as meagre, and we would suggest to the editor that it should be considerably amplified or omitted altogether. The subject of varioloid, or modified small-pox, for instance, is dismissed in three lines:—

"*Varioloid*, or modified small-pox, occurs in cases where the patient has had the more severe form previously, or has been vaccinated; it is also caused by *inoculation*."

On the difficulty of observing eczema in the vesicular stage the editor has some most appropriate observations, and a case which was treated at the Dispensary for Diseases of the Skin, in which vesicular, impetiginous, and erythematous eruptions occurred on different parts of the body at the same time, is referred to.

For the treatment of itch the preparation which has found great favour among military surgeons is a mixture of the penta-sulphide of calcium and hyposulphite of lime, readily made by boiling one part of quick lime with two of sublimed sulphur in ten of water. The editor has found this mode of treatment most efficacious in a very large number of cases.

With regard to the causation of prurigo senilis, it is remarked by Dr. Belcher:—

"By some dermatologists the occurrence of the pediculi is considered as only an accidental circumstance, and not constituting a symptom of the disease; by others it is regarded, more correctly I think, as an essential feature of the eruption, and they have therefore, following Alibert, denominated the form thus characterised, prurigo *pedicularis*."

We have always thought that the ablest chapter in Dr.

Neligan's work was that which treats of the squamous class of cutaneous diseases, and as the writer of this notice was a student under that energetic physician for two years previous to the appearance of the work, and had opportunities of seeing the very cases from which his descriptions were drawn, he can vouch for their great accuracy. This chapter is therefore the one to which our editor, with every anxiety to include in the work the most recent information, has been able to add least.

The chapter on diseases of the hair and nails, and that on the therapeutics of skin diseases, have been greatly enlarged, and in the latter the references have been made to the British Pharmacopœia. A most copious bibliographical index, and one of words and matters, concludes this really standard book, and renders it more indispensable than ever to the practitioner.

THE ARTS OF ROWING AND TRAINING. By ARGONAUT. London: Horace Cox. 1866.

TRAINING for the various athletic sports has become no unimportant art, and in all circles where athletic exercises are pursued, even in our universities, we find certain members who set themselves to the task of professional and practical training. Nor is it a matter of small necessity that this art should be practised upon sound principles of physiology, since it really takes in hand the constitutions and the lives of numbers of young men who are the healthiest and best representatives of strength in the country.

The monograph entitled "The Arts of Rowing and Training," by Argonaut, although evidently not written by a physiologist, is the work of a careful and accurate observer. The book lays down no empiric rules, and while it is calculated to divest the public mind of the vulgar prejudices and absurd notions of raw beefsteaks, it provides the professional trainer and his pupils with a short concise hand-book of plain directions, the fundamental bases of which are temperance, soberness, and chastity, by which they can pursue healthy training—i.e., the maintenance of the frame in such a state of vigour that it is enabled to perform severe bodily labour without injury to the system.

In the first chapter the author endeavours to correct the prevalent erroneous impressions disseminated by sensation writers on the statistics of mortality of the university crews. These he contrasts with the mortality of jockeys—a class among whom an injurious method of training is perpetually practised.

In the next chapter he discusses the means to be employed, and, instead of recommending excesses in any way, he condemns them altogether. He deprecates in the highest degree the old and injurious systems of sudorifics and purgatives for reduction of weight, recommending only the natural means—viz., healthful exercise, while the system is to be invigorated by good sound food and refreshing rest, regular hours, and ablutions, not forgetting other sanitary measures, as ventilation, &c. The diet recommended is most liberal and wholesome; instead of nauseating with a continuance of underdone meat, every variety of plain properly-cooked fresh meat, with vegetables, eggs, bread, butter, lettuces, and light puddings, is ordered, as well as a daily allowance of one and a half pints of ale, two glasses of port wine after dinner, and tea with the morning and evening meal rather than coffee.

The greatest care is advised regarding the choice of men to row; those unaccustomed to it are not suddenly to be put into training, but first to be taught lessons of self-denial, such as the eschewing of smoke and alcoholic excesses, and thus gradually to be prepared for more strict regularity in the habits of daily life, while every candidate for an oar is recommended to undergo a thorough medical examination,

in order to ascertain whether there is any physical condition of any of his organs that would forbid the practice of severe exercise.

The object to be attained by the course proposed in this little book is a reduction of fat, particularly of internal and excessive adipose tissue, an improvement in the muscular tone, and a healthy active condition of the secretory and excretory organs. The means of accomplishing it are sound, and not in any way injurious, and the book is a valuable guide to all who can enjoy healthful recreations.

LECTURES ON HYDROPHOBIA. Compiled from MS. Notes of the late Dr. T. S. HOLLAND. By T. C. SHINKWIN, M.D., Demonstrator of Anatomy, Queen's College, Cork.

So few Surgeons have had the opportunity of observing more than an isolated case of hydrophobia that little attention has ever been directed to the subject, which is, nevertheless, worthy of more commendation. Surgery should never rest satisfied with the conclusion that it has failed to master the pathology or treatment of any disease. Dr. Shinkwin's Lectures have been read *seriatim* by our readers, in THE MEDICAL PRESS, and are full of interest and information on this peculiar subject. The brochure is altogether the best essay on dog madness which we have seen, and, now that such close attention is accorded to diseases of the inferior animals, will be read with interest. We don't believe in the impossibility of cure in any disease if the true pathology can be made out, and the treatment, prophylactic and curative, based on it.

ON THE SURGICAL TREATMENT OF VESICO-VAGINAL FISTULA. By AWLY P. BANON, F.R.C.S.I. Pp. 15.

DR. BANON details ten cases of successful operation for this disease and one of partial cure—eight of which were effected by a single operation: an unusually large proportion of successful cases for one operation. They are not, however, correctly defined as vesico-vaginal cases, one being uterovesical, another recto-vaginal, and one of lacerated perineum. Dr. Banon varied his operative proceedings between the Bozneau's and Marion Sims' method, and employed with success a barbed instrument of his own invention, for transfixing the edge of the wound before paring it off. It is creditable to Surgery that an operation so much dreaded for its uncertainty should have been reduced to as successful a line of treatment as many others which are not subject to the same difficulties.

CONTRIBUTIONS TO PRACTICAL MEDICINE AND SURGERY. By JAMES ARNOTT, M.D.

WE have received the title and preface, and pages 43 to 58, of these contributions. We shall be glad to notice them when the entire work reaches us.

A SURGEON KILLED ON A RAILWAY.—A frightful accident occurred on the Erewash Valley branch of the Midland Railway at Codnor Park on Tuesday last. About one o'clock Mr. Featherstone, surgeon to the Butterley Company, was driving across the branch line which leads from the company's works at Codnor Park to the warehouses at Ripley. The vehicle in which he was driving was covered with a tilt, and as it was crossing the rails two empty coal waggons, which were being shunted off a pick-up train from Chesterfield to Nottingham, ran into and smashed the conveyance to pieces, killing Mr. Featherstone on the spot. The horse and Mr. Featherstone's servant (who was driving) escaped unhurt, although the servant was so terrified that he was for a time insensible. Directly after the accident one of the railway porters ran off to Mr. Featherstone's for assistance, being then ignorant of the fact that it was Mr. Featherstone himself who was killed.

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 7, 1866.

THE SICK AND INFIRM POOR IN WORKHOUSES.

THERE is now some chance that the unfortunate class of our fellow-creatures who have been reduced to the rank of paupers by sickness, old age, or other infirmity, will at last receive at least the treatment which we adopt towards our sick horses, our cows, and our pigs, but which we have hitherto almost denied to human beings. The political newspapers which formerly almost entirely ignored even the existence of paupers, and closed their pages to any tales of suffering which might be related of them, now vie with each other in filling their columns with the details of Coroners' Inquests in Workhouses, with the minutes of the Poor-law Board, with the reports of Poor-law Inspectors, and with the censures passed upon local Guardians. We and other Medical writers, who have been behind the scenes, and who knew the previous impenetrability of the general Press and the Poor-law Board to any sympathy with sick paupers, might well characterise the present spasmodic zeal as a piece of gross hypocrisy, did we not believe that the agitation now in progress, however late it may have come, is likely to be of service in removing the evils which have long existed, have repeatedly been exposed, but have never been redressed.

As we have before remarked, it is no part of our duty to enter into any discussions as to the general principles of the Poor-law system; to inquire into the value of the labour test as applied to paupers; to compare the conditions of vagrancy and crime; to determine the method of treating tramps in the casual wards, or matters of a similar character. If healthy people are too idle to work, or if ordinary work cannot be found for them, it is quite right that they should be made to earn their living by such labour as is suitable to their condition and previous occupation. But when the healthy man, woman, or child becomes sick or infirm, whether he or she be a pauper, or a tramp, or even a criminal, he becomes the legitimate object of public compassion, and enters peculiarly into the beneficent province of the Medical practitioner.

In former periods of the history of England, as is very well known, and in most Continental nations as in the present day, the care of the sick and infirm poor was intrusted to the numerous religious communities which the genius of Christianity had introduced into Europe. But in this country the endowments of the Monasteries having been alienated to secular uses, and distributed as bribes to the nobles to insure their con-

currence in the policy of the Eighth Henry, the relief of the sick and the distressed was either discontinued altogether or left to the operation of private charity. From the latter source arose many of those munificent endowments for the education of the needy, the care of the insane, the treatment of the sick, and the repression of crime, which are among the greatest glories of the British nation, and more especially of the British metropolis, where hospitals exist on a scale of palatial splendour, and are supported by princely revenues every day increasing in amount. But this very circumstance, like the accumulation of wealth among individuals, tends only to make the surrounding poverty and distress more conspicuous; and thus, even among the sick and disabled poor, we have on the one hand an aristocracy who are sumptuously entertained and taken care of in the hospitals, and on the other a commonalty who are left to die in the streets, to languish with fever or other infectious diseases in their own miserable dwellings, or to vegetate in the dismal dens provided by the Poor-law. This law, which, in its nature and origin, is really a just and beneficent one, is intended to supply the want of private charity, and to equalize the treatment of those who are afflicted with illness or other causes incapacitating them from earning their livelihood. But the statute of Elizabeth, framed for this purpose, inevitably led to abuses, arising, however, rather from the lapse of time and the consequent changes in men and manners, than from any defect in the original design. Thus, in modern days, the distinction between rich and poor has been drawn more widely than ever, and, what is more, there are not only rich and poor individuals, but rich and poor localities, and every day sees the rich withdrawing more and more from the quarters inhabited by the poor, and the poor vanishing from the vicinity of the rich. Thus, a Poor-law, applying alike to Bethnal-green, or Shoreditch, or Whitechapel, and to Belgravia and St. George's, Hanover-square, is really a very unequal and unjust law, because the latter districts have comparatively very few poor, and the former have too many; and the rates, being collected locally, press with great severity upon the poorer quarters.

Now, the New Poor-law, as it was once called, and which is now in operation, was intended to reconcile many of these anomalies, and to introduce a uniform system for the relief of the poor; and the Poor-law Board was established in order to carry out these views. So far as the general machinery of this Board is concerned, we have no fault to find; and the details of income and expenditure have no doubt been very properly adjusted, audited, and allowed, in the several Unions and Parishes; but the treatment of the Sick Poor by this Board, and in connexion with the Sick Poor the treatment of the Poor-law Medical Officers, has been in almost every case most shameful; and the tardy steps now taken by the Board at the eleventh hour to retrace its course, will very insufficiently atone for the years of insolence, neglect, and injustice, of which the

Poor-law Medical Officers have so justly, so loudly, and so persistently complained.

The Poor-law Board, being invested by law with the power of controlling the local Boards, and, if need be, of adjusting complaints between the latter and the Medical Officers, has almost invariably taken the part of the local Boards; and however much the Medical Officers may have been in the right, they have entirely ceased to expect any mercy or consideration from the potentates at Whitehall. Hence, we unhesitatingly affirm that the Poor-law Board is culpable for nearly all the abuses in the management of the Sick Poor which have long existed, but have only recently been brought to light. The Poor-law Board knows perfectly well that the insalubrious condition of the Workhouses, the want of efficient nursing for the sick, the harshness of officials towards the patients, and other abuses, have been repeatedly brought under its notice by Medical Officers. The Poor-law Board, if it chooses to produce them, has written documents substantiating such complaints; and if it has not more of such evidence, the Board knows that it is suppressed because the representation of the truth on the part of the Medical Officers would insure their dismissal from their ill-requited posts. When the Poor-law Board might have influenced public opinion and might have done much to obviate and prevent the abuses now so prominently brought before the public, it utterly neglected to take any steps whatever, and in deference to the local Boards, withheld the evidence which even *its own Inspectors had presented to it*. Some of these Inspectors had actually measured the amount of cubic feet of air allowed to the sick paupers in some of the Workhouses, and although in this and other particulars the arrangements were found not only insufficient, but dangerous to health, yet these and other similar facts were quietly held back, until in the year 1865, the Board pretends to rub its eyes and to manifest an intense zeal for improvement, and makes a merit of floating with the general current of public opinion.

Contemptible, however, as we think the conduct of the Poor-law Board towards the Medical Officers and the Sick Poor, and culpably negligent as we believe it to have been in the performance of its duties to this afflicted class, we nevertheless accept its co-operation in the present movement, which has not only obtained the favour of the general press but the sympathy of many of the rich, and even the patronage of the nobility. The public will at last do what the Poor-law Board might have done long ago, if, instead of slavishly yielding to the ignorance and the arrogance of the local authorities, it had stood forth to befriend the Sick Poor and to vindicate the rights of humanity.

MRS. MAPP, the bone-setter, visited the Grecian Coffee-house once a week in her coach and four from Epsom in 1736. Mrs. Stephens received £5000 from Parliament in 1739 for communicating the secret of her solvent for stone in the bladder.

EDUCATION AND TRAINING OF THE IDIOTIC AND IMBECILE CHILDREN OF IRELAND.

IN a recent number of this Journal we furnished our readers with a full report of a meeting held at Charlemont House, of historic memory, during the month of February last. It is now our wish to call the attention of the profession to the object of that meeting, to urge them to take the position in this matter to which their calling justly entitles them, and to suggest to them the advisability of supporting the proposed movement by every means in their power.

According to the last Census, there were 7033 idiots in Ireland, of whom on the day when the Census was taken 403 were in lunatic asylums, 21 in prisons, 934 in work-houses, 5675 at large, either wanderers, mendicants, or under the care of their friends. It appears that in the year 1861 there were in Ireland 470 idiots under the age of 10 years, 618 between 10 and 15, and 805 between 15 and 20, giving a total of 1893 at an educational age.

When we consider this state of things, and reflect at the same time that in almost all countries, save Ireland, institutions have been established for ameliorating the condition of the most helpless and unfortunate of our fellow beings, we cannot but admit that Dublin, with its many charities, with its numerous asylums, hospitals, and schools, still wants what is now proposed to be established—a special institution for the idiotic and imbecile children of our fatherland. On the grounds of political economy, it is certainly a sound undertaking, but more so on the grounds of Christian charity and duty.

From the statistics above given, it appears that idiots are sometimes placed in lunatic asylums. Now, to anyone who has investigated the psychology of the question this must appear to be a very insane practice. A lunatic asylum is, perhaps, the worst place in which an idiot could be placed, and for such as live in a place of the kind no description can be more hopelessly true than the rhyme of Dr. WATTS—

“Like brutes they live, like brutes they die.”

The Commissioners in Lunacy have lately reported to the House of Commons that a lunatic asylum is a most unfit residence for an idiot; and they have placed on record their conviction, which we heartily endorse, that the treatment of this unfortunate class is a mixed moral and medical one; in other words, that it is one with which medical men are peculiarly concerned, and one which cannot be properly conducted without their hearty coöperation.

Space would not here allow us to enlarge on the details of the now celebrated and successful asylum of this kind at Earlswood, in Surrey; of those in other parts of England and Scotland, on the Continent, and in America; of the painstaking and unwearied methods of education and care adopted in these asylums, and of the varied literature of the subject. At a future time we purpose to enter more fully into some of these questions, but meanwhile we must call attention to the fact noted by the ARCHBISHOP of DUBLIN in his speech at Charlemont House—that in this, as in most other charitable and humane projects, our profession takes the lead. On the committee newly formed to collect funds, and carry out the project of establishing an institution of this kind in or near Dublin, are leading metropolitan members of our own profession; and it would be unjust to conceal the fact, that to the profession of medicine, and to its literature, we owe the origin and

moving spring of this transaction. Dr. KIDD, of this city, who, as is well known, is the learned editor of our contemporary, the *Dublin Quarterly Journal*, not only published—or rather printed for private circulation—his most interesting “Appeal on behalf of the Idiotic and Imbecile Children of Ireland,” from which we have taken many of the facts above stated; but he also organized the first meeting, and now spurs the matter forward by his untiring energy. We wish the project God-speed, and we urge its well-being on the profession.

FURTHER EXTENSION OF “THE MEDICAL PRESS AND CIRCULAR.”

THE subscribers to the MEDICAL PRESS AND CIRCULAR will perceive that we have to-day redeemed our promise of further extending the limits of the journal, whenever the demands on our space should render necessary such an increase. From this day forth our readers will receive forty pages of matter instead of thirty-two, which has hitherto constituted the limit of the journal—an addition of two-thirds to the MEDICAL CIRCULAR and of eight pages to the MEDICAL PRESS. We have been compelled to adopt this course by the rapid multiplication of the claims on our space for advertisements and contributions, and we hope by it to place ourselves in a position to accommodate all the requirements of advertisers without unduly sacrificing the interest of the journal to our readers, and that the delays which have been hitherto unavoidable in the publication of communications will also be obviated.

We hope that this improvement in the MEDICAL PRESS AND CIRCULAR, which is achieved at a very considerable expense, will be accepted by the profession as a guarantee for our desire to place the journal in a foremost position, and to advance, *pari passu*, with its growing importance.

THE CONVEYANCE OF LUNATICS TO ASYLUMS.

IN the Report submitted to the Directors of the Royal Edinburgh Lunatic Asylum, at the annual meeting which was held last week, there are many points of great interest discussed in Dr. Skae's usually forcible style. But there is one matter alluded to, to which we beg specially to call the attention of our readers, as it is a subject of great importance. It refers to the manner in which persons who have been declared to be of unsound mind are conveyed to the Asylum. We all know something of the horror with which lunatics are regarded by ignorant people, and this feeling sometimes leads to the use of very injudicious and hurtful treatment to the poor patient; and in order to provide for his safe conveyance to an asylum, the most extraordinary and uncalled-for measures are sometimes had recourse to, which as Dr. Skae points out, are often productive of lasting injury to the insane. The following is that part of the Doctor's report which treats of this subject:—

“Patients continue to be brought to the asylum in mechanical restraint—several had handcuffs on when they arrived, and one gentleman was brought not only secured by means of ropes, but stupefied with chloroform, and guarded by five men! It appears very singular that such things are still done in this country, when it has been so generally

made known that in almost every case a patient will come quietly to an asylum if he is told where he is going, the reason for it, and if the necessity for it is made apparent by the simple presence of one or two experienced attendants authorized to remove him.

"It is not easy to estimate the amount of injury done to patients who are taken to asylums by sheer force or under false pretences. It tends to destroy their confidence in the medical officers and their friends, and to mar the efforts made for their recovery, or even for their comfort. There are inmates of this asylum now, who have been here for years, and who up to this day resent kindness, refuse advice, and repudiate every attempt to gain their confidence, because they were entrapped, as they say, into the place, or brought to it under some false pretence. One such case is worthy of especial notice, to illustrate the evils resulting from such malpractice. A gentleman was admitted upwards of four years ago, who to this day affirms he was brought into the asylum under a parcel of lies; that if he had been told he required to come here, and had the reasons explained to him, there is no one that he would have treated with greater respect than myself, or whose advice he would have valued more; but as he was entrapped here illegally, as he maintains, or by false representations, he will take no advice from me. He would not even accept his discharge from me, or even from the Commissioners in Lunacy, who, he thinks, have condoned the act which placed him here."

These are sensible remarks, and coming from one who has had so large an experience in the management of the insane, they are worthy of the attention not of the public only, but of the Profession as well. In country places in particular, medical men should see that the patient, who by their certificates has been pronounced to be a lunatic, is subjected to no undue force or ill treatment in his removal; and they ought to endeavour to impress the public with what Dr. Skae here points out—viz., "that in almost every case a patient will come quietly to an asylum if he is told where he is going, the reason for it, and if the necessity for it is made apparent by the simple presence of one or two experienced attendants authorised to remove him."

Deceit should especially be avoided, for it makes the patient suspicious and shakes his confidence in every one about him, so that all efforts made to restore him to a proper state of mind are frequently unavailing.

URQUHART V. BONNAR.

THIS case, which has been twice tried by a jury, and on both occasions decided in favour of the pursuer, came up again before the first division in the Court of Session on Friday last, when the defender moved for a new trial. The pursuer is a shoemaker in Cupar, and the defender is Dr. Bonnar, a medical practitioner in the same town. The issue that was sent to the jury was, whether the assignation of a policy of insurance was signed by the pursuer when he was under essential error as to its nature and effect, induced through fraud and misrepresentation, or undue concealment on the part of the defender. The defender now asks for a new trial, on the ground that the verdict in previous trials was contrary to evidence. The chief points of interest in connexion with the case are these: Dr. Bonnar, the defender, had been the medical adviser of the pursuer from the year 1845. In October, 1858, the pursuer was the defender's tenant of a shop in Cupar, at a rent of £18, which was payable yearly at the Martinmas term. At that time Urquhart did not owe the doctor one farthing of rent, and he had a general account against Dr. Bonnar for shoes and boots furnished to his family. Whereas the doctor had no account against Urquhart for medicines, for all the medicines that were

got in Bonnar's shop were paid for with ready money. Pursuer had his mother, an old woman close upon eighty years of age, living with him, and as at that time Urquhart was in very bad health, he was desirous of making some provision for the support of his mother in case he should die before her. He spoke to the doctor about having his life insured, and the defender brought the proposals to the pursuer to get them filled up, saying that it was best to apply to two different offices, for if one did not accept the other might. Urquhart says he filled up one and the doctor filled up the other. The insurance was effected, and, according to Urquhart, Bonnar retained the policy in his possession; and that in May, 1859, when the pursuer was in very bad health, Bonnar called upon him, and asked him to give him an assignation of his policy as a security. And the pursuer declares that the assignation was obtained from him without his being made clearly to understand the nature of it. Dr. Bonnar, on the other hand, swears that the assignation was read over to the pursuer before he signed it, and that he knew perfectly well the nature of the transaction.

The discussion of the case was adjourned, and we have not been able to ascertain whether leave for a new trial has been granted.

It is much to be regretted that such an action should ever have come before a court of law. For however innocent Dr. Bonnar may be in regard to the accusations that are made against him, the very fact of his being connected with such a transaction at all cannot fail to injure him in his professional relations. And we have no hesitation in expressing it as our most decided opinion, that it is a very wrong thing for any medical man to have anything whatever to do with the insuring of a patient's life, and more especially when the patient is in a precarious state of health.

Such a transaction may be carried out with the greatest honesty, no doubt, and we cannot believe that Dr. Bonnar has been guilty of anything approaching to fraud or wilful misrepresentation, but in acting as he did he has laid himself open to suspicion, and furnished the public with matter for scandal.

MEMORANDA OF THE MONTH.

"*Ars longa, vita brevis.*" life short, the art of healing tedious, said Mr. Shandy—a free translation of the line in Hippocrates, applicable to the cattle plague, its therapeutics and pathology. Dr. Copland, the Johnson of medical-dictionary makers, gives his adherence to the diet of Worms, while the patentees of certain disinfectants have found favour with the Royal Commission.

The University of Cambridge has taken a step in the right direction, by the appointment of two Professors—one of Human Anatomy and Physiology, to which Dr. Humphry was elected unanimously amidst the congratulation of his friends; while for the second professorship, that of Comparative Anatomy and Zoology, there was a sharp contest between Mr. Newton, of Magdalen, and Dr. Drosier, of Caius; the former elected by 110 votes to 82.

A very able paper by Dr. Whewell, Master of Trinity, appears in *Macmillan's* of this month. The author takes as his text the late able "Hunterian Oration" of Dr. Acland, of Oxford, and rather severely analyses the philosophy of the Huxleys and the London University, as represented by these and Dr. Carpenter. He strikes suggestively and well at the cant of morphology and "force."

Sir W. Fergusson, in locutions after his operations a few days ago, drew the attention of his class to what he styled a "new procedure" in bad cases of fungus testis, that of not cutting it away as malignant, but returning it to its natural cavity in the tunica vaginalis. Sir William admitted that London had been learning from Edinburgh of late in such matters. Mr. Syme had originated the idea that this ugly fungus has a microscopically harmless structure after all, and should not be shaved away or the testis amputated, as was customary in the routine of London practice and elsewhere. Compression of the fungus does good, but patients will not attend to it sufficiently, so that on the whole this simple plastic operation of Syme is best.

As to whether such a testis fungated is of subsequent value, Sir William added to these "wise saws" a modern instance of some interest, that of a man with one testis lost, who underwent this operation on the other, or second, yet in the normal course of events proved to be the father of a child; so that the operation is one, as amusingly remarked, which preserves an organ that is more than merely ornamental.

Mr. Flower has read the first part of a memoir on the osteology of the sperm whale (Huysetar), pointing the moral of his tale by a back bone and head of a giant skeleton recently put up at the College of Surgeons, of which the head alone is represented to weigh over one ton, the length of the whale (realising some of the ever-amusing ideas of Guidbad), forty-six feet! This Titan skeleton is indeed a grand accession to the instructive riches of the Hunter Museum, more than can be said; perhaps, for a series of water-colour drawings representing—to wit—portions of skull sliced away by sabre cuts, skulls shattered by falls, swords through the throat, and such subjects.

The day we happened to be in the museum, a fashionable lady visitor was looking at the sketches. We can stand a lady apothecary at surgical operations. These drawings are very first-rate as works of art, but are nevertheless painful and wearisome as works of feeling or taste, and the sooner they are consigned to some chamber of horrors at Netley, the better; they teach nothing, and, as regards the art of the physician, they are incongruous and painful.

A gratifying instance of royal patronage bestowed on one of our most deserving and useful medical institutions, the Surgical Home, at Notting Hill, by H.R.H. the Prince of Wales, is to be noticed this month. Few of our smaller "special" hospitals in London (excepting, perhaps, the Ophthalmic at Moorfields), can boast of such "spolia opina" in favour of cures as this, where the needle and knife of Mr. Baker Brown have had such various triumphs in female diseases. A royal cheque for 25 guineas, and good wishes for the success of the institution, with other marks of royal patronage, have accordingly crowned the labour of years with a just meed of public approbation.

HOMŒOPATHY AND THE CATTLE PLAGUE.

THE Report of the Association for the Trial of Preventive and Curative Treatment of the Cattle Plague by the Homœopathic method, the company so well bepluffed by the *Times*, which appears under the auspices of the Duke of Marlborough as chairman, announces the collapse of the Association. The reasons given are twofold—firstly, that Homœopathy had proved a failure; and secondly,

that even if it had not, the determination of the Government to trust no more in physic has deprived the Association of its occupation. Here is the best that can be said of the trial:—

"That it has now been three months in operation, having had extensive experiments carried out in Norfolk, Yorkshire, Cheshire, &c. The general result has been a conviction that, while very much may be done by isolation to prevent the spread of the disease, and considerable success has attended the practice of remedial treatment when assisted by careful nursing and proper diet, yet the degree of constant watchfulness needed for the due administration of homœopathic remedies is so great that much success by this system in so new and formidable a disease can hardly be expected from any others than skilful veterinary practitioners, or persons conversant with the system and method of practice."

"The greatest watchfulness and skill are requisite in carrying out the homœopathic treatment, each symptom, as it manifests itself, requiring specific attention, and thus calling for a greater extent of competent medical assistance than can be obtained. The legislature having now ordered the slaughter of infected and suspected animals, the efforts of the Association must necessarily be suspended."

Oh! lame and impotent conclusion, but not unexpected by the profession. Homœopathy can now divide the opprobrium of failure with Mr. Worm's treatment, and with vaccination, with this distinction, that failure comes worst from those who brag most, and that legitimate medicine, if it has done little, has at least promised nothing. Great has been the boast of globulism and proportionately severe is its fall.

Correspondence.

POOR-LAW MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall feel obliged by your finding space for the names of the following gentlemen, who have forwarded subscriptions to the Association during the past week.—I am, &c.,
RICHARD GRIFFIN.
12, Royal-terrace, Weymouth, 24th Feb., 1866.

Subscriptions received by Mr. Griffin.—Olivy, H. P., Taunton, 4s.; Cooper, W., M.D., Thingoe, 10s.; K. J., 4s.; Westell, T. Cookham, 21; R. J., 11s.; Morris, G., Hereford, 5s.; Thomason R., Hereford, 5s.; Hanbury, G., Hereford, 5s.; Lane, J. C., Hereford, 5s.; Sankey, F. H., Bridge, 10s.; Norman, G. B., Basford, 10s.; Simpson, R., Settle, 5s.; Dobson, T., Windermere, 5s.; Holme, W., Kendal, 5s.; Hope, 5s.

Subscriptions received by Mr. Prouse.—Thompson and Felce, Launceston, 21s.; Marshall, J. L., York, 10s.; Williams, W. and Son, Guilsborough, 10s. 6d.; Mann, C. T., Boxford, 5s.; Jones, J., Ross, 10s.; W. S. Rootes, Ross, 10s.; Dowson, A. H., Orford, 5s.; Furber, G. H., Muidstone, 5s.; Smith, R. L., Clare, Suffolk, 5s.; Williams, T. Pouty-pool, 10s. 6d.; Hughes, R., Bala, 10s. 6d.; Cogan, C. C., Greenwich, 5s.; Kingdon, A. S., Combarton, 5s.; Yeoman, J., Whitby, 10s.; Vise, A. B., Holbeach, 10s.

Mr. Griffin has forwarded to those Members of the Association who have subscribed during the last twelve months, a pamphlet of 52 pages and the following letter:—

"12, Royal Terrace, Weymouth, March 1st, 1866.
"Dear Sirs,—The accompanying pamphlet is intended to be sent to each Member of Parliament so soon as we can get some gentleman to undertake the introduction of a bill into the House of Commons. It is possible the proposed bill may not meet with the entire approval of all, but it must be borne in mind that it is almost impossible to meet the views of every one, and much will depend upon the member who introduces the bill as to the exact clauses that shall be retained. I intend to apply to one or two members about bringing in the bill, but as it is possible they may not accede to my request, I hope each of you

will consider that it devolves upon you individually to find a member; by adopting this course we shall be sure of success. Should any of you require a pamphlet to send to a member to whom you may write, I will supply you with it. I regret I can only send pamphlets to the Medical Officers who have subscribed within the last twelve months, as the present subscription will only about cover recent expenses. I therefore trust that if any of your colleagues intend to subscribe, they will do so without loss of time, in order that the printer may strike off the requisite number of copies, as the type of so large a pamphlet cannot be reset without great expense. It may possibly be said that much of the present pamphlet is merely a transcript of former ones, which I admit. Indeed I only view it as a rearrangement, with some additions, of much that has been written before; but had I not adopted this course, a majority of the present House of Commons would know nothing of the matter, and would take it for granted that the late Select Committee on Poor Relief (England) had fully gone into the subject, and from the

evidence laid before them had decided that there was no need of fresh legislation, whereas now they will see that the subject was not fully gone into by the Select Committee and that the evidence of a Poor-law Inspector had grossly misled them.—I am, dear Sirs, sincerely yours,
To the Subscribing Poor-law Medical Officers
of the last twelve months.
RICHARD GRIFFIN.

QUACKS AND QUACKERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The subject of quackery has recently been much discussed in medical circles, and measures for its suppression have been recommended. Permit me to offer a few practical hints to the same end.

I conceive, as there are two classes of quacks, the remedies must be of two kinds; one for the class who have a legal medical qualification, another for those who have none. The former class should be directly amenable to the body who granted their qualification; the latter can only be reached by efficient penal enactments. If, for example, a member of any College outstep the legitimate bounds of the Profession, by advertising or other unworthy means of acquiring practice, such College should have power to suspend, or altogether cancel his diploma. Another salutary means of combatting this class of quacks would be the withholding of all professional courtesy in their regard, and the refusal of consultation with them. Some of our most distinguished members can do good service to the Profession by adopting the latter idea. Practical legal powers are necessary to carry out most of these suggestions, and how are those to be obtained? I believe only by purely medical representation in Parliament. It is scarcely fair, nor is it generous, to blame the General Medical Council for the existence of those evils and for others yet unredressed. . . . The Council has done good service if only in raising and approximating to uniformity in these kingdoms the standard for preliminary education. But the voice of the Council, which I take to represent the Profession, must be heard and felt in the House of Commons before we shall obtain laws calculated for the better government, welfare, and dignity of the Profession.

Apologising for intruding upon you, and with a hope of again touching upon the subject, I am, Sir, yours truly,
1, Lower Dominick-street. P. C. LITTLE, L.R.C.S.L., &c.

ABUSES OF THE RED-TICKET SYSTEM IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The abuses of the ticket system may be conceived by the number that were cancelled last year in the Drumshambo Dispensary District being 103. As this cancelling usually takes place *after* the medical officer's attendance has been completed, and as he receives no remuneration for that attendance, here is an instance in which his private practice was interfered with—and by the parties, too, that ought to protect him in that respect, to the extent at least of his salary, which is only £100. The cancelling is a proof, or it would not have taken place, that the parties were able to pay, and probably would pay £1 at least each, if they had not been improperly recommended. I could cite several instances in which the medical officer's private practice is in this manner interfered with in poor districts, where, at best, it must be very limited. The average valuation of dispensary districts is about £16,700, which affords some ground for practice; but there are fifty dispensary districts whose poor-law valuation averages less than £5,000, and yet I find that in several of these the medical officer's practice is much injured by unfit parties being recommended.

Though dispensary committees are legally empowered to give tickets, directing the medical officer "to give medicine and advice to, or attend, any poor person resident" in the district, it does not follow that they are legally empowered, or equitably justified, in directing him to attend any rich person, or in other words one who is able to pay for that attendance. The members of the committee usually reside in the district, and of course know the circumstances of those whom they recommend; and as, by the Poor-law Commissioners' orders, the medical officer is bound to attend until the ticket is cancelled, even though he knows the party to be wealthy, it is but fair that he should be remunerated for that attendance by some party.

I beg to suggest that in a case in which there can be no difficulty to prove that the holder of a ticket is not poor, but is notoriously in such circumstances as to be able to pay for medical attendance, the person that gave the ticket be processed by the medical officer for his attendance on the person so recommended; and that another case be selected in which the patient's material condition is such that he cannot be considered poor. If the assistant barrister's decree be favourable to the medical officer in the first case, very few committee men will in future give tickets except to those whom they know to be poor; and if favourable in the second, very few wealthy persons will apply for tickets. But if, on the other hand, the barrister's decree be adverse, that decision will make it necessary for government and parliament to interfere, as after such decision they cannot leave the medical officers at the mercy of the committees, by compelling them to attend rich and poor.

That the salaries of many poor-law medical officers are inadequate to the duties they perform, and to the position they must hold in society, is certain; and this must be the more felt in poor districts, in which there

cannot be much private practice. Unfortunately, many dispensary districts were formed more according to the views of proprietors than for public convenience. Many have less population and area than one medical man can attend; and, if he be resident, less property than affords a moderate private practice; whilst many districts in charge of one medical officer are so populous and extensive as to make efficient attendance apparently impossible. For instance, who could attend a population of 23,369, scattered over a district of 73,848 acres, or 115 square miles; or a population of 20,058, with an area of 82,633 acres, or 115 square miles; or even a population of 9,021, with an area of 146,841 acres, or 223 square miles? The salaries range from £25 to £175; but twenty-six are only £75, forty-eight are £70, and forty-six range from £65 to £25. Some of these are held by medical officers that have a second dispensary, but many are not. The subject of salaries and the better arrangement of districts deserve the attention of a select committee; and if a portion of the consolidated fund be given, as in England and Scotland, to pay half the salaries of the poor-law medical officers, same would be judiciously appropriated as an addition to those of such as receive low salaries in districts in which there is comparatively little property, and some, it is to be hoped, to be the nucleus of a fund for making a tolerably efficient provision for widows and orphans. It may not be amiss to observe that this fund is given to the boards of guardians, not to the medical officers; but if received by the guardians in Ireland, it might induce them to be more liberal.

I perceive by a copy of the English Poor-law Superannuation Act that only "those whose whole time has been devoted to the service of the union or parish" can be superannuated; and I learn that the chaplains, clerks, and medical officers are not eligible for it. This is unfavourable as to Ireland, especially in this year of despondency, when additional burdens are being put on the poor-rate.

Perhaps the following may interest your readers. In 1861 the total expenditure for medical relief under the poor law in England and Wales was £238,233, of which £180,134 was paid in salaries to the medical officers, and £4,050 under the *free-care* system. The population was 17,814,564 (certain Gilbert unions being excluded), and the area 34,882,633 acres. The medical officers numbered 3,479; but as some held two districts, the actual number is considered to be about 3,000. Their salaries, &c., averaged about £61 8s. each, exclusive of "fees for midwifery and surgical cases." Their districts contained an average population of very nearly 6,000, and averaged in England about 10,000 acres, or fifteen square miles; in Wales, about 26,000 acres, or 40 square miles.

If the poor-law medical officers intend to ask for a House of Commons committee, they should begin to obtain and prepare the necessary information to lay before it.
DENIS PHELAN.

27th February, 1886.

DR. RICHARDSON'S ANÆSTHETIC SPRAY PRODUCER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I used the "spray producer" in two cases with marked success; one, a case of abscess in the neck; the other, a superficial abscess of the breast. I applied the spray for three minutes on each occasion (using common ether), and neither of the patients *felt any pain from the knife*. As the anæsthetic spray producer is under trial, I think the above facts may not be uninteresting to the readers of your valuable journal.—I remain, dear Sir, yours faithfully,

HENRY GRAY CROLY.

UNEDUCATED MIDWIVES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A few days since I was called on to attend Mrs. C—, confined of her ninth child, and found two uneducated women in charge of the patient, who have been in the habit of taking upon themselves the responsibility of attending females in labour; and they had led the husband to believe the case was going on favourably—and there was no need to send for a doctor, as they told him his wife would soon be better.

However, on the evening of the second day they agreed I should be sent for, when I learned the patient had been thirty-six hours in labour, and that the child had escaped into the cavity of the abdomen through a large rupture of the uterus. I at once made known to the husband the hopeless nature of his wife's case. She died in an hour from my first seeing her, and being satisfied that the child too was dead, I did not make the Cæsarean operation to extract it till a considerable time after her death, which I did at the request of her husband, and discovered that the child's head was enlarged to the size of an adult's with upwards of two quarts of clear water.

Had the true nature of the case been ascertained before the rupture of the uterus had occurred I have no doubt the mother's life could have been saved by a slight puncture of the fetal head at the presenting fontanelle.

The mother was a strong muscular woman with *tissue adipose* an inch in depth.

I send you this case for the information of junior members of the Profession, and to caution the public not to trust females in childbirth to ignorant hands.—Faithfully yours,
J. MAXWELL, M.D.
Lisnaska Union, Derrylin Dispensary District,
February 28, 1886.

ON THE PREVAILING CATTLE PLAGUE AND ITS TREATMENT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having visited and personally examined the stocks of owners in neighbouring districts near Perth affected with rinderpest of late, it appeared to me that the treatment used was not as one would expect from the symptoms present, and I did not wonder that it had no effect in abating or curing the above disease. The poor animals were kept shivering from over-ventilation and small quantities of gruel were given them. Consequently down they came all the more rapidly from their former appearance, and by-and-by the watery discharge from eyes and nostrils, and following this, one of a purulent nature, accompanied with cough and difficult breathing, characterised to be the true pathology of rinderpest, ending fatally in five, six, or seven days; but deadly although it has been, and is, this ought not, I think, to hinder a cure being attempted. On some of the dead animals which I dissected, the whole alimentary canal was of an unusual flacid aspect. This was in the early stage of the disease, and it appeared to me to be what one might expect in gastro-enteric disorders, and therefore I did not hesitate in coming to the conclusion that very different treatment from that referred to was required, I suggest the ox-sulphure of antimony and calomel and ipecacuanha in doses for cattle, mixed together and given every evening with a drink of warm gruel afterwards; the latter drink to be given three times a day during the first stage, and also in the next stage, when cough had come on and purulent runnings at eyes and nose, and when difficulty of breathing ensued, mustard poultices should be applied to the throat and breast externally. I can truly say that this kind of treatment which I tried had a good effect, and I am still using the same, and have not found anything else to answer so well if used early and in diarrhoea the tincture of muriate of iron is likely to do good, according to my experience in the animals affected recently. To some, common salt is of great benefit.—Yours, &c.,

G. K. H. PATERSON, L.R.C.S.I., L.R.C.S. Edin., &c.

Balbaghee and Perth, Feb. 28, 1866.

THE DOUBLE QUALIFICATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read the letter in your paper of this day, entitled "The Double Qualification" and signed "L.R.C.S.I. and L.K. & Q.C.P.I."

I quite agree with your correspondent that Irish students should rather qualify here than go to Edinburgh; and I fully approve of his proposal to have a double qualification from the College of Physicians and the College of Surgeons here. With all respect, however, I dissent from his statement that "the character and prestige of a college do not depend so much on the character as on the number of its constituents." My opinion is just the reverse of this. If his view be the true one, then indeed the Edinburgh Colleges of Physicians and Surgeons are greatly superior to ours in character and prestige; but that they are not is well known all over the world. Your correspondent further states that "one of the Colleges, from its apparent disinclination to progress, is beginning to be looked on more in the light of a club than a medical college."

I do not wish to judge of any one's intentions, but if this insinuation be intended for the College of Physicians, I can only say that your correspondent errs "*longe, lateque*." Let him look at the published Register of that College for the present year, and he will see sufficient to convince him of the character and prestige of its constituents, of its real professional progress in the right direction, and of its being a *bona fide* medical college, in the highest sense of the term.

I have reason to believe that this proposed double qualification has not been overlooked by both colleges here; further, that the principle is generally approved of, while the difficulties of arranging the details are not insuperable. To be practical—I beg to suggest that your correspondent should get the fifth of the medical students to whom he refers to address temperately-worded memorials to the President and Fellows of the College of Physicians and to the Council of the College of Surgeons, and I am sure that the matter will receive due consideration.—Yours truly,

Dulbin, Feb. 28, 1866.

MEDICUS.

MISTAKEN POLICE DIAGNOSIS.—An inquest was held by Mr. Carter on the body of a man named Thomas Hayward, aged fifty-six. He was found lying on the pathway in Newington-butts, and taken to the station-house, where he was charged with being drunk. On examination by the surgeon, it was found that his right leg was broken. He was then removed to the hospital and ultimately expired after great suffering. The house-surgeon of St. Thomas's Hospital stated that the insensibility was caused by pain. The coroner, in summing up, said there had been a great many deaths of late in police cells, and otherwise, caused by constables taking people up for being drunk, while they were in reality dying. He should, however, advise them to be more careful for the future. Verdict, "Accidental death."

UNIVERSITY OF DUBLIN, TRINITY COLLEGE.

EXAMINATION FOR MEDICAL DEGREES.

HILARY, 1866.

MIDWIFERY, &c.—DR. SINCLAIR.

1. The most reliable signs and symptoms of pregnancy, and the earliest period of gestation at which each becomes available for diagnosis?
2. Describe fully the line of treatment you would adopt, and the rules you would enjoin, in a case of ordinary *accouchement*, from delivery to convalescence.
3. What may give rise to retention of urine—
 - a. During gestation;
 - b. During labour;
 - c. After delivery?
4. Given a case of "cross-birth," with one of the fetal hands in the vagina, how would you determine the exact position of the child *in utero*?
5. Describe the following cases of shoulder presentation:—
 - a. In which version could be performed with facility;
 - b. In which version could be performed, but with difficulty;
 - c. In which version ought not to be attempted.
6. Describe the mode of performing the operation of evisceration.
7. Causes of abortion—
 - a. Maternal;
 - b. Ovuline?
8. Describe the natural progress of the vaccine vesicle on the human subject, from the first appearance to the falling of the crust, stating the day on which each phase is perfected.
9. What modes of treatment may be adopted for dysmenorrhœa arising from stricture of the canal of the cervix uteri?
10. What symptoms arising would lead you to order a carminative mixture for a newly-born child? Write a recipe for one.

DR. LAW.

1. What is the generally received explanation of the first sound of the heart?
2. How does pathology favour this explanation?
3. What is supposed to be the cause of the second sound of the heart?
4. How does pathology favour this supposition?
5. Under what pathological conditions of the heart is the greatest amount of hypertrophy and dilatation of the organ met with?
6. Under what conditions is concentric hypertrophy met with?
7. What are the contingencies that may occur in a case of phthisis pulmonalis to hasten the ordinary fatal termination?
8. What are the points of agreement and difference in the physical signs and constitutional symptoms of a case of cirrhosis of the lung and phthisis pulmonalis?
9. How many different diseases of the kidney are comprehended under the designation, "Bright's disease?"
10. What is the point in which all agree?

MEDICAL JURISPRUDENCE.—ROBERT TRAVERS, A.M., M.B.

1. In the dead body, what circumstances will distinguish between *rigor mortis* and the rigidity produced by idiopathic tetanus, or that of strychnic poisoning?
2. An adult human body being found suspended by a cord encircling the neck, how can it be determined whether death was the result of hanging or of some other cause?
3. State the symptoms and treatment of poisoning by oxalic acid; or a soluble oxalate, and the mode of detecting such poison in the matters rejected from the stomach, or found in it after death.
4. What are the objections to Marsh's process for the detection of arsenic in suspected liquids?
5. Under what circumstances may a wound of the heart not be immediately fatal?
6. What is the mode in which the *Physostigma venenosum* destroys life? and how will its action be recognizable during life?
7. How can you determine that a red or reddish-brown stain on a white garment, is due to the colouring matter of blood? and, if so, whether that blood have been human?

8. Why is not sufficient evidence, that the child had been born alive, supplied by the *docimasia pulmonum*?

9. By what characters will an incised or a punctured wound be shown to have been inflicted on the body during life?

10. Is suicide necessarily a proof of insanity? if not, in what cases is it not to be so regarded?

PRACTICE OF MEDICINE.—DR. STOKES.

1. With what diseases is a varicose state of the epigastric, mammary, and intercostal veins, commonly associated?

2. Describe the disease called sea scurvy. State how far the exclusive use of salted meats is to be taken as its exciting cause.

3. Describe the disease termed "*Petechiæ sine febre.*"

4. Give the treatment of acute and passive purpura hæmorrhagica.

5. What are the principal sources of danger in these diseases?

6. How would you proceed to reduce or return hæmorrhoidal tumours?

7. Give the treatment of the affection.

8. Write a form for an anodyne enema used as an opiate suppository.

9. Miasmata are divided into the animal and paludal. Compare their effects on the system.

10. Give the general relation of these miasmata to endemic and epidemic diseases.

DR. R. W. SMITH.

1. Give a description of the disease termed "*canerum oris.*" Mention its treatment.

2. To what disease is it analogous?

3. Mention the general and local causes of pyæmia.

4. Describe the constitutional symptoms that attend it.

5. Give the situations and peculiar characters of pyæmic abscesses.

6. A limb may be suddenly seized with gangrene while in a perfectly sound condition, where there has been no injury, nor have any of the ordinary causes of gangrene been in operation. To what would you ascribe its occurrence under such circumstances?

7. Describe the appearances of a sore that has been attacked with hospital gangrene.

8. Mention the predisposing causes of this form of gangrene, and state how you would treat it, locally and constitutionally.

9. In what cases would you employ ice to produce local anæsthesia?

10. Contrast the disease termed by Mr. Hamilton "*tubercular syphilitic sarcocele*" with the ordinary syphilitic disease of the testicle.

DR. R. W. SMITH.

1. Contrast mollities ossium with rickets.

2. Pathology of mollities ossium?

3. Mention the causes of death in cases of caries of the temporal bone.

4. How would you distinguish between separation of the lower epiphysis of the humerus and luxation of both bones of the forearm backwards at the elbow?

5. What is the nature of the displacement when the clavicle is broken external to the trapezoid ligament?

6. Enumerate the methods of treating fistula lacrymalis.

7. What are the differences between phlegmon and phlegmonoid erysipelas.

8. Describe Syme's operation, termed the "perineal section."

9. Give an accurate description of the true Hunterian chancre.

10. Symptoms of mercurial erethismus?

SURGICAL ANATOMY.—DR. McDOWEL.

1. Describe the coraco-clavicular ligaments, and mention how they influence the motions of the scapula.

2. Give a description of the thyroid body—its arteries and veins, minute structure, and supposed uses.

3. Assign the length of time during which the epiphyses of the humerus and those of the radius remain united by cartilage only.

4. Describe the operation for securing a wounded gluteal artery outside the pelvis. Point out the difficulties and dangers of the operation, and mention any causes of the operation you may have seen or read of.

5. What irregularities of the femoral artery may affect the

success of the operation of tying that artery for the cure of aneurism?

6. The parts divided in tying the femoral artery after Porter's method? What objections have been urged against that operation?

7. Give the anatomical relations of the urinary bladder.

8. The distribution of the facial nerve (seventh pair)?

9. Enumerate the muscles attached to the thyroid cartilage.

10. The course, relations, and distribution of the external popliteal nerve.

DR. ADAMS.

1. What are the forms of tumours of the nerves observable?

2. What is meant by the case of subcutaneous nervous tubercle?

3. What is the surgical treatment in these two cases?

4. Mention the names of those writers who have described the different forms of nervous tumours, as well as the subcutaneous nervous tubercle.

5. Describe the ordinary case of prolapsus ani, and say what examination you would institute to discover the cause of the complaint.

6. What do you mean by internal as contrasted with external piles?

7. Name some of the surgical operations and means resorted to to afford the patient relief from piles.

8. As a general rule, which of the surgical operations recommended do you consider as safest and best?

9. Describe a case of indolent carcinoma, or schirrus, of the female breast; and say what accompanying local symptoms would prevent you recommending amputation of the breast in the case.

10. What forms of ulceration of the tongue may be confounded with the cancerous form? and how would you distinguish one from the other?

ACTION FOR DETENTION AGAINST THE NORTH BRITISH RAILWAY.

ON Friday, the 26th, Dr. Alex. Wood brought an action in the Small Debt Court before Sheriff Campbell, against the North British Railway Company, for the expense of hiring a conveyance from Penicuik to Edinburgh, and other losses to which he had been exposed by the delay of a train for upwards of an hour on the Peebles line on the 21st ult. The agent of the railway company admitted the facts, but pleaded that the delay arose from a cause which no care or foresight could have prevented, and brought the engineer and guard to prove that a pipe of the boiler had suddenly given way, that the engine was a good engine, and appeared to be in perfect order when it left Peebles. The pursuer, on the other hand, offered to lead evidence to prove the frequent irregularity of the trains on the North British line, and stated that he brought this action to try whether the public had no remedy against the inconvenience and loss to which they are thus continually exposed. The agent for the defenders objected to any general evidence for the pursuer being led, and asserted that the trains on the North British were more regular than those on any other Scotch lines. The Sheriff held that the proposed evidence was inadmissible, and that the pursuer must confine himself to the particular occasion specified in the summons. One of the witnesses for the pursuer, Mr. Bowie, engineer, who had likewise been detained on the day in question, spoke very strongly of the miserable station at Penicuik, where passengers had been so long detained on an inclement winter day. In pronouncing judgment for the defenders, the learned Sheriff stated that he had great sympathy with the pursuer, who had evidently suffered great inconvenience. At the same time, he was bound to decide against him in this case, as the company had proved to the satisfaction of the Court that the delay was accidental.

BLACK SHEEP.—The General Council has informed the Royal College of Physicians that the name of Abercrombie and Whalley have been removed from the *Medical Register*. The Council also request that no person whose name has been struck off will be admitted to examination by any licensing body.—*Brit. Med. Jour.*—[Why has the College of Physicians been specially informed of the expulsion of Whalley and Abercrombie from the Register? E. D. M.P.C.]

RETROSPECT OF JOURNALS.

A MICROSCOPICAL Society has been started at Nordhausen in Saxony among the butchers in search of trichinæ in pork; in addition to the full price to be paid for every animal thus affected, a premium of fifty thalers to the discoverer is promised.

At the meeting of the Royal Medical and Chirurgical Society on the 13th inst., Mr. Thompson gave the details of a case of phosphatic calculus which had been crushed by the lithotrite; the nucleus was found to be composed of bone which had evidently been a sequestrum detached from the os innominatum. At the same meeting, Mr. J. Allen described a mulberry calculus $7\frac{1}{2}$ ounces in weight, for which the ordinary lateral operation had been performed.

Mr. J. Hutchinson contributes a valuable paper on dislocations of the os innominatum, fractures of that bone, dislocations of the hip, and on separation of the upper epiphysis of the Femur. He draws attention to the extreme frequency of rupture of the bladder or urethra, as a concomitant symptom of injuries of the pelvis. He has been as successful as others in reducing dislocations of the hip by manipulation instead of traction.

Dr. Ogle makes some original remarks on the formation of Aneurism in connexion with embolism of the artery.

The *Medical Times and Gazette* of the 24th draws attention to the "statistical mare's nest" discovered by the *Lancet* in reference to the hardships about to be undergone by the Fenian prisoners at Pentonville. According to the statement in last November, it was shown that 10 per cent. of the convicts had to be sent to Broadmoor Criminal Lunatic Asylum. It now turns out that they were sent there, not in consequence of their lunacy, but because they were required for the purpose of working in the newly-laid out grounds in the asylum.

A leader is given on the subject of the "Thermometer in Disease" as a means of diagnosis, especially in cases of acute disease.

A Contributor of high literary attainments, who signs himself "S.P.E.," gives an amusing and faithful account of Medical Manners in the nineteenth century.

A very ugly piece of business is brought to light from the Antipodes. Dr. Turnbull, of Melbourne, operated on a case of ovarian tumour. The case turned out unsuccessfully, but he manfully published the details in the *Medical and Surgical Review* (Australian). A writer whose extreme acrimony induced him to sign his name as "NO.," and who turns out to be the Editor of the *Australian Journal*, writes a most offensive letter, almost accusing the operator of manslaughter. The publisher of the *Medical and Surgical Review* intimates to his subscribers that in consequence of not being able to find an impartial Editor, he is obliged to discontinue its issue.

Mr. Haynes Walton contributes a case of night blindness in a sailor.

Mr. L. Tait draws attention to the successful treatment of Colles' fracture by Gordon's (Belfast) splint.

Dr. Richardson describes the tests for pure ether, as is used by him in producing local anæsthesia.

We have the first report on the existing treatment of fracture in the London Hospitals; it merely alludes to preliminaries such as beds, &c. In the enumeration of stiff apparatus, the method of using glue is alluded to as follows:

"Glue.—This is the best commercial French glue. It is first softened by being soaked in cold water, and is afterwards heated over the fire till it liquefies. A fifth or an eighth part of methylated spirit is added in order that it may 'set' more rapidly. This substance makes a very good stiff splint—light, strong, durable,—and when carefully put on, very presentable in appearance."

The *Lancet* gives the particulars of the recommendations of the Committee appointed to inquire into the condition of the Army and Navy Medical Officers. They have apparently gained some real permanent advantages in the

way of pay; these concessions have come very opportunely on the eve of the competitive examination next month; but it is hard to please everyone; for instance, Sir James Gibson "protests against the greater favour shown to the navy by the above recommendations, and we fear that the army medical officers will not be satisfied with the terms of retirement, improved though they be. On the whole, however, we believe that these recommendations will be received with gratification, and certainly the Services owe much to Dr. Markham and Mr. Busk for their careful and laborious investigation of the claims of the officers and assiduous attention to the duties of the Committee."

We have reason to believe that the probationers at Netley have requested to be allowed to exchange into the Indian Medical Service.

Some of the London vestries are indignant that their Medical Officers should have given publicity on recent occasions to their views, as to the filth and want of sanitary improvement in certain populous localities.

As the Medical Officers of Health have formed themselves now into an association for the purpose of discussing matters connected with sanitary reform, we may expect that opinions will be even more outspoken than formerly. Their immediate expulsion is advocated in a local print.

Mr. Bateman, the eminent civil engineer, proposes a scheme for the supply of London with water. The idea is as chimerical as that for the supply of Dublin from the Varty; it is conceived, however, on a grander scale, suited to the magnificence of the metropolis. He proposes securing the rainfall at the source of the Severn in the neighbourhood of Wales, and conducting the water thence by an aqueduct 170 miles long to London. The estimated saving to the consumers of soap, &c., by this substitution of a soft for a hard water is £400,000 per annum.

The mercantile marine are supplying numerous cases of sea-scurvy. Some one or other is to blame for neglecting to carry out the provisions of the Merchant Shipping Act in reference to the supply of lime juice.

Prof. Huxley, at the Royal College of Surgeons, is at present engaged in lecturing on the *Manatee* and now extinct *Rhytina* of Siberia.

In a letter on syphilisation, Mr. H. Coote gives his experience of the process as afforded by five cases; it must be regarded as unfavourable, in one case secondary symptoms came on.

In Mr. Hilton's lecture, he details the cure of a case of popliteal aneurism by flexion; also a case of fracture of the olecranon with dislocation of the forearm forward—an accident not often seen.

Dr. Wright describes a new pessary for the treatment of flexions of the uterus.

Mr. Buchanan describes the particulars of three cases of strangulated hernia; in one case the origin of the rupture was congenital; the operation was performed at the age of 72. In another case a considerable portion of omentum was removed; in the last the sac suppurated some time after the operation; all terminated favourably.

Mr. H. Greenway describes a new bed for suspending the leg. It appears rather cumbersome and not likely to supersede Latier's swing cradle, which fulfils all requirements.

Sixteen cases from Mr. T. Holmes' practice are detailed chiefly in reference to excision of the elbow and knee; the results after some years have been encouraging.

Iodoform is now extensively used as a sedative, especially in cancerous affections of the uterus.

The *British Medical Journal* has a leader on the garlic cure for the cattle plague, and draws attention to the number of eminent and sensible people who have been taken in on the subject.

At the Medico-Chirurgical Society's meeting at Edinburgh, Dr. Sanders described a case illustrative of a remarkable physiological and pathological fact, and one which we confess we read with astonishment for the first

time about four years ago—namely, that the faculty of speech depended on the integrity of the *left* frontal convolution of the brain. The idea was first broached by M. Broca. In Dr. Sanders' case the aphasia (loss of speech) was accompanied by right hemiplegia. It is not simple want of articulation that is meant, but the faculty of willing that act that is alluded to. After death softening was discovered in this locality, but extending to the corpus striatum.

Mr. Henry Smith draws attention to the exhibition of large doses (thirty grains) of iodide of potassium in some forms of obstinate secondary syphilis.

Foreign Medical Literature.

ON THE PATHOGENY OF CYSTOID KIDNEYS.

By W. KOSTER.

(Continued from page 202.)

Translated from the *Nederlandsch Archief voor Genees- en Natuurkunde* te Deel, 2e Afdeling, Utrecht, 1864, for THE MEDICAL PRESS AND CIRCULAR.

By WILLIAM DANIEL MOORE, M.D. Dub., M.R.I.A.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS, OF THE NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

b.—Statistical and Pathological Study of some Cases of Renal Cystoid.

ACCORDING to Förster's statement, above mentioned, cystoid renal degeneration occurs "at every age, even in the fetus."

Although I will not say it is impossible that renal cystoid should be developed, for example, at 18 or 20 years of age, such an occurrence is a rare exception. In connexion with other considerations this fact will, at the close of this essay, lead us to a theory of the process. I should, therefore, in place of Förster's words, rather say, "In advanced age and in the fetus," for it is remarkable that a process occurring in the fetal condition should manifest itself most frequently in advanced life.

The cases of renal cystoid recorded in detail in medical literature, are to be found in Rayer's well-known book, "*Traité des maladies des reins*." I have not been able to discover any subsequent cases separately recorded; and Rayer, who has examined so many diseased kidneys, also calls the cystoid degeneration rare.*

I here refer only to the cases which have occurred in adults, for the cystoid degeneration of the kidneys during intra-uterine life is not so very rare. Virchow, in his classical essay,† first distinctly directed attention to this fact, and he appended important considerations upon the origin and consequences of this degeneration. We shall revert to this point.

That renal cysts in general occur chiefly in advanced life, is a well-known fact. "Like M. Rayer (says Lebert), I have been struck with the frequency of renal cysts in the aged." Rayer's expression, to which Lebert here alludes, is to be found in the *Maladies des reins*, t. iii., p. 512—"We frequently meet with simple cysts in the kidneys of the aged, we observe them more rarely in the kidneys of adults and of children; however we have seen

* "There are, in fine, cases (after speaking of renal cysts in general) where, without appreciable renal antecedent affection, the two kidneys are attacked with a true general encysted degeneration of the cortical substance, &c. &c. The cases of complete encysted degeneration of both kidneys are rare."

† R. Virchow. Ueber congenitale Nierenwassersucht (on congenital dropsy of the kidneys), in *Verhandl. der med. phys. Gesellschaft in Würzburg*. Bd. V., p. 447. *Gesamm. Abhandl.* p. 864.

‡ *Anatomie pathologique*, i., p. 299.

them even in infants." For scattered renal cysts occurring accidentally, or in other fundamental morbid processes in the kidneys, this statement may hold good; it appears less correct to apply it directly to the cases of proper cystoid degeneration, as we have seen Förster, among others, do.

I shall here briefly mention the cases more fully detailed by Rayer, stating the age of the patient, where this is given:—

1. Darles, aged 40 years. (*Journal de médecine de Corvisart, Leroux et Rayer*, t. xvii., p. 501).
2. Marie Anne Baussant, aged 30 years (Rayer).
3. A woman of advanced age (Rayer).
4. Guillaume R., aged 49 years (*Journal de médecine de Corvisart, &c.*, p. 399).
5. Finot, aged 48 years. (Some suppuration with the cystoid degeneration, Rayer).
6. Madame H., aged 29 years. (Almost always suffering, and subject to articular pains, *addicted to drink*, Rayer. In this case one of the kidneys was so large, that pregnancy had been suspected during life. It was not purely cystoid degeneration. Many spots of the kidney resembled tuberculosis, others were more like what occurs in the second stage of Bright's disease).

In Cruveilhier's well-known atlas cases of hydronephrosis and purulent pyelitis, mentioned with renal calculi, are to be met with; but none of actual cystoid kidneys.

Gluge* represents kidneys (Fasc. xvi., Pl. ii., figs. 1, 2), having externally quite the appearance of those examined by me. No particulars respecting the patients are, however, given. In the drawings, little of the renal pyramids is to be seen; what is represented appears atrophied and streaked. He says, however, of the medullary matter, "that it is pale red, and its structure is normal." After having elsewhere spoken of cyst formation in the kidneys in general, he expresses himself thus with respect to cystoid degeneration: "When the whole kidney, or both are changed into cysts, a general cause cannot be established. This appears to lie in the kidney itself, but is as yet unknown (l. c. Fasc. xvi., pp. 9-12). It is remarkable that in fig. 3 of the plate just now referred to in Fasc. xvi., where a portion of the renal tissue from the pyramids with cysts is represented in the *apparently very much increased connective tissue, many dark irregular granules are represented.*†

Lastly, we find in Lebert's work, ii. page 373, a case mentioned, but without any statement of the patient's age. The description of the kidneys (which were brought to him by an intern of the *hôpital des Vénériens*) quite agrees with that of total cystoid degeneration.

If we compare the cases on record with one another we shall find that in by far the majority cystoid degeneration of both kidneys occurs not in young persons. Four of Rayer's six are forty years and upwards. The two younger persons are women, and in one we have not to do with a genuine case. The only case of extensive cyst-formation in the kidneys in a very young person, which subsequently might certainly have become complete cystoid degeneration, is recorded by Beckmann (*Virchow's Archiv*, Bd. xi., p. 123). In the body of a well-nourished and apparently perfectly healthy girl of 19, who was killed by a fall, B. found the *kidneys large, and the cortical substances of both studded with cysts of various sizes*. B., however, mentions the case only cursorily (without, he says, again reverting to it) in order to speak of the changes of the Malpighian corpuscles. With surprise we read at the end of the short communication, "the pyramids were perfectly normal." Moreover, it appears from the recorded cases that an accurate investigation of the structure of the pyramids, especially of the renal papille, in cystoid alteration of the kidneys, either could not have taken place (on account of the far advanced degree of degeneration), or was not carried out in connexion with a definite idea of the origin of cystoid degeneration. When we examine what changes have been found by Virchow

* *Atlas der pathologischen anatomie*.

† *Vide infra*.

in the papillæ renum in the fœtus, we are easily led to think of corresponding changes after birth.

Both in his essay upon uric acid infarction in the fœtus, and in new-born infants*, and in the later essay upon congenital cystoid kidneys already quoted, the genesis of renal cysts is repeatedly spoken of. In the investigations, too, of O. Beckmann we meet with cursory remarks on the origin of cysts in adults. We shall not examine in detail the cases of cystoid degeneration in the fœtus, investigated by Virchow, and his observations thereupon. On the whole, it is certain that he was the first to perceive the relation of the uric acid infarction, and of the atresia of the papillæ renum as the primary element in the formation of fetal cysts.

In all the cases previously observed, referred to by Virchow, no means of pathogenic explanation were found in the results of the investigation. In the case examined by him he demonstrated obstruction of the tubuli uriniferi in the papillæ renum by solid uric acid (*Ueber Harnsaure-Abscheidung*, u. s. w., l. c., pp. 182 and 183). In the corollaries at the end of this essay it is said, under No. 3, "such an excretion (of uric acid) is met with exceptionally also in the fœtus; and in such cases it gives rise to dropsy of the kidneys without obliteration of the ureters." The further investigations of uric acid infarction, without alteration of the kidney, immediately after birth, and the forensic importance of the same are well known, and do not belong to our subject.

In the investigations on congenital "renal dropsy" the examination of the children's bodies is described in detail, a distinction being made between the cases communicated by earlier writers, who confounded hydronephrosis and renal cystoid with one another, and the change of the renal papillæ already mentioned, described in its bearing on the origin of cystoid degeneration: "But I believe the atresia of the papillæ cannot be explained otherwise than by a fetal inflammation of these parts" (*Ueber congen. Nierenwassersucht*, p. 459), in which the uric acid infarction likewise comes under consideration. Still more distinctly had the influence of the latter already been expressed: "It appears to me scarcely doubtful that the degeneration of the kidneys has thus proceeded, that first of all an obliteration of the tubuli uriniferi through uric gravel took place in the pyramids, that the upper portion of the tubuli uriniferi and the Malpighian capsules filled with urine became dilated, partly atrophied the surrounding tissues, and induced a degeneration of the kidneys into a spongy substance, studded with many cysts of various sizes" (*Ueber Harnsaure-Abscheid.*, u. s. w., p. 183).

From the description of the kidneys examined by me, it appeared that, with the cyst formation in the cortical substance, increase of the interstitial connective tissue in the summits of the pyramids, and an extensive calcareous infarction in the tubuli uriniferi existed, while neither were calcareous granules wanting in the connective tissue. The result of these processes was a more or less complete atresia of the renal papillæ.

It seems to me not unreasonable to assume a connexion between these last processes and the cyst formation, the processes which effect the atresia of the renal papillæ being the primary element. The excretion of urine proceeds unimpeded in the cortical substance, but the excreted fluid cannot escape from the tubuli of the pyramids. Accumulation of urine takes place, and distension (and bursting?) of the canals will readily follow at the point most remote from the mechanical obstacle. In the distension of the capsulæ glomerulorum and of the convoluted tubes (only a few cysts are met with in the pyramids) in consequence of the high pressure to which the excreted urine which cannot escape is subjected; and in the processes depending thereon (compared with chronic inflammatory processes) we therefore recognize the causes of the origin of the renal cysts in our case.

The calcareous infarction in the summits of the pyra-

mids is a recognized fact. Very often we find white streaks in the papillæ renum without further morbid changes being discoverable, while micro-chemical investigation shows that these white streaks are formed by solid calcareous salts in the tubuli uriniferi. In many cases, however, some scattered cysts are met with in the kidneys, together with the presence of a slight calcareous infarction. The circumstance, also, that both processes are peculiar to the period of involution, occurring most frequently in the kidneys of old men, points to a causal connexion between the two. By many pathologists, moreover, following Virchow, the dependence of some renal cysts upon calcareous infarction of the tubuli uriniferi in the pyramids is assumed.

As to the nature of the calcareous infarction and the question whether renal cysts are very often dependent thereon, especially whether the complete cystoid degeneration is connected with it, opinions vary, or we find silence observed in reference to the point. Nay, Virchow, who at first considered the causal signification of the calcareous infarction in renal cysts as very probable, subsequently became vacillating in his opinion. We first find mention made of the matter in his essay, "*Ueber Harnsaure-Abscheidung*," &c., l. c., pp. 840 and 841. After the account of the obstruction of the canals of the pyramids in the fœtus by uric acid, he says: "This is clearly seen in the examination of the kidneys of adults, in which, according to my observations in most cases of simple renal cysts, an obstruction of the straight tubuli uriniferi by calcareous deposit takes place." However, in the notes to the later edition in the "*Gesammelten Abhandlungen*," p. 858, he added: "Nevertheless, the closing of the urinary canals by calcareous deposits is seldom quite complete, and I therefore believe that I must the rather modify my former view, as, with the calcareous deposits, other changes are usually present, which explain a still more complete interruption of the urinary excretion."

Förster, probably influenced by Virchow's ideas, is likewise not steadfast in his opinion: "Calcareous infarction is met with especially in advanced life, as calcification of cast-off and broken-up epithelium; sometimes, also, it is produced by overloading of the urine with calcareous salts in destruction of the bones; it was hitherto only an object of observation on the dissecting table. Not improbably the obstruction of the tubuli uriniferi sometimes leads to dilatation of the latter and to the formation of cysts."

As to the "other changes" to which Virchow alludes in the passage above quoted, as occurring together with calcareous infarction in cysts, we find little said. In his most recent work, "*Die krankhaften Geschwulste*" (Morbid Tumours), p. 271, the occurrence of renal cysts is cursorily treated of, and he says: "But the ordinary course of the development is rather this, that the cystoid kidneys have in general nothing whatever to do with a retention of urine, but that they arise in consequence of a chronic interstitial nephritis, which is connected with a deposition of solid albuminates in the interior of the tubuli uriniferi," &c.

It hence appears that so extensive a calcareous infarction, with atresia of a great part of the renal papillæ, as occurred in the case described by me, has not been observed. As to what had happened in the cases of complete cystoid, formerly recorded, we can, of course, form no opinion.

I shall speak later of the signification of the calcareous infarction and of the other changes in particular, but at present my case appears to be of importance, because—1st, it may probably again attract more attention to the influence of calcareous infarction; and 2ndly, the other changes of tissue in an early period of cyst-formation were observed, whereby it may perhaps be useful in affording clearer views of the nature of the same.

Besides scattered observations on calcareous infarction we find in O. Beckmann (*Virchow's Archiv*, xi., p. 121) mention of a case accidentally discovered of extensive cyst-formation, with calcareous deposit in the papillæ,

* *Verhandlungen der Gesellschaft für Geburtshülfe in Berlin*. 2ter Jahrgang, pp. 170, et seq.

in a woman, aged 65, who died of pneumonia. On the surface of the kidneys were numerous cysts, and also many in the pyramids. But of the infarction, in connexion with Virchow's modified opinion, little is said.

In general, we find in Beckmann's essays a very great hesitation in assuming the existence of obstruction or closing of the pyramidal tubuli, alternating with evidences of the great probability thereof, in connexion with the results of Virchow's investigation of the fetal cystoid degeneration. Beckmann asks himself whether changes of tissue in the arterial substance of the kidneys do not rather lead to the formation of cysts. He thinks it improbable (Virchow's *Archiv*, ix., p. 236) "that such cysts should be formed in adults by the closing of straight tubuli uriniferi, as we know that the pyramids in general are seldom severely and independently morbidly affected, and it is difficult to imagine the obstruction of a straight tubulus uriniferus with a free current from above (?) But if a closing should, in fact, take place, the possibility of a cyst-formation must be admitted. However, the majority of cysts have been found in the cortical substance alone; the question would suggest itself whether in morbid affections of the cortical substance the possibility of closing of the tubuli and of accumulation of urine follows as a matter of course." He considers this, however, to be in most cases improbable, and the occurrence of cysts, especially in parenchymatous inflammation, to be impossible. On the other hand, "more chronic or interstitial inflammatory processes" might, perhaps, be taken into account, an opinion which, as I have already said, has been expressed also by Virchow in general terms, but without more accurate definition.

To make our pathological consideration of the cases of cystoid kidneys, and of extensive cyst formation in general on record complete, we must finally allude to the opinion of Virchow on those cases which, chiefly in youth, have been met with when death ensued from other diseases. One of the cases communicated by Beckmann (page 213), some others spoken of by him or Virchow, where no fresh causal processes for the production of cysts were met with, and where the excretion of urine during life had not been remarkably impaired, almost constrained the adoption of the hypothesis, "that such forms date from the period of fetal existence." In the part of the "*Krankhafte Geschwulste*" already quoted the same opinion is expressed: "It is easy to understand the possibility of a partial fetal degeneration being kept up until a later period of life, and it is conceivable that the urinary excretion should cease in the cysts and be replaced by other deposits."

The considerations contained in this section I shall now apply to the elucidation of my views respecting the pathology of cystoid kidneys. To this I shall add a word on renal cysts and hydronephrosis, compared with one another, together with some remarks on diagnosis.

(To be continued.)

ABSTRACT OF
METEOROLOGICAL OBSERVATIONS
TAKEN AT THE MILITARY HOSPITAL, NICE,
FROM THE 10TH TO 31ST JANUARY, 1866.

By Dr. CABROL,

CHIEF PHYSICIAN TO THE HOSPITAL.

Translated by R. CROTHERS, M.D., Nice.

THE atmospheric pressure has varied from 0.766 to .775, but it has been generally between .770 and .775, indicating settled fine weather.

The temperature during the night has always been several degrees above the freezing point. Not a trace of white frost. Very little moisture.

The daily temperature has ranged from 44 to 63. No cold. The temperature mild and agreeable. Very little wind. Slight breezes from N.N.E. and E. Temperature of the earth at a depth of 20 centimètres (8 inches) has been 46; of the sea, 59½. The end of the month of

January is in general one of the periods most favoured under the climate of Nice. This year it has been very evident, the ten days just passed having been very fine. No high winds; but in general a slight air from the east, cooling and modifying the ardent rays of the sun, which has shone with splendour. These winds have brought some clouds over Nice (*strati lumuli*), but rarely sufficient to obscure the brightness of the sun.

The nights have been beautiful—cool, but without damp. The air clear and bright. The sea in general calm; occasionally some slight waves, caused by the winds and depending on their direction. In presence of such favourable atmospheric conditions there has not been anything worthy of being called an invasion of disease; the few fresh attacks may be summed up as slight and unimportant affections, yielding readily to very simple remedies. Some affections of the skin have appeared, but of an ephemeral character. The progress of chronic diseases, as rheumatism and broncho-pulmonary affections, has been favourable; exempt from complications and aggravations which might be attributed to local influences or to climate. These affections, which are ordinarily aggravated under the influences of cold and humidity, have been singularly alleviated by this very favourable state of the atmosphere, recalling often during the last ten days the mild and agreeable sensations of the summers of more northern latitudes.

In fine, the decade just past has been one of the most agreeable even in this highly favoured country.

FROM THE 1ST TO 10TH FEBRUARY, 1866.

The mean height of the barometer has been from .762 to .768 (30 inches to 30 4-10ths), indicating moderately fine and slightly variable weather. The thermometer *min.* during the night has always marked several degrees above zero (32 Fahrenheit), consequently there has not been any cold, not even hoar frost. The absence of fogs and humidity, which have been prevalent in other places, establishes for this country a sanitary advantage. The daily temperature has varied between 8 and 17 (46½ and 62), accompanied with the sensation of heat. The temperature in the sun has risen to 43 (110°) at one o'clock p.m. That of the sea, 15 (59); of the earth 52 at a depth of 20 centimètres (8 inches). The winds have blown from the N., N.E., and E., with but little force. This decade has presented meteorological phenomena of remarkable mildness. Rain fell on the 2nd, but only for some hours and in small quantity; and although the sky has been sometimes sprinkled with fleecy clouds, and at intervals even cloudy, the sun has seldom ceased to shine with brilliancy. Under the influence of its rays, and the absence of dew during the nights, the ground has become very dry, and had there been high winds the dust would have been very disagreeable. Nevertheless, the vegetation has not suffered, for it is now in all the beauty of verdure and flowers. The almond trees are entirely covered with blossoms.

The only diseases which we can refer to these phenomena should naturally be mild; they are confined to slight excitement of the nervous system and trivial attacks of rheumatism.

The sore throats, colds, indigestions, &c., which we remarked in January, are now less numerous. Some isolated cases of pertussis have been observed with children, but less severe and obstinate than in the north, yielding to ordinary means and without any mortality.

The weather could not be more favourable for the amelioration of chronic diseases of the chest, whatever may be the distressing symptoms which they present. It is also beneficial to children and young persons, favouring their healthy development; also to persons weakened from various causes, by strengthening them, and preserving them from affections from which they would suffer in cold and humid climates. *En résumé*, during the last ten days, this meteorological and medical state has been very favourable under all its aspects.

THE DISCOVERY OF THE TRICHINA.

It may be recollected that a considerable amount of correspondence took place a short time since in the several newspapers, on the subject of the discovery of the trichina spiralis, in connexion with the disease to which this parasite gives rise in the human subject. A paragraph first appeared in the pages of the *Pall Mall Gazette*, a paper sometimes well-informed on medical subjects, to the effect that the history of the trichina and trichinialis was not well understood, and that "extensive series of experiments had led to no definite result." This very erroneous statement was at once copied into the *Times*, which in medical matters possesses or exercises no power of discriminating physiological facts from semi-scientific twaddle; and the appearance of the paragraph having excited some alarm in the minds of the public, it not unnaturally called up Dr. T. Spencer Cobbold, the most experienced helminthologist in this country, who corrected the misapprehension, and referred the reader to trustworthy treatises in which the subject was discussed. Here the discussion, as far as the general press was concerned, might and ought to have stopped, but several letters subsequently were allowed to appear, some of the writers claiming the merit of discovering the trichina for British observers, and others for Germans, till at last the editor of the *Times* seems to have been so bewildered between helminthology and high Dutch, that he declined to insert any more letters on the subject. Dr. Cobbold has, however, very properly put together a notice of the history of the trichina, and has published it in the *Lancet*, and it must be admitted that the details, although of great interest to physiologists and pathologists, are quite devoid of attraction for, if they are not quite incomprehensible to, the general reader, while the subject itself has a kind of repulsiveness which renders it an inappropriate topic of general conversation. Dr. Cobbold, so far as we can perceive, has given a very fair and impartial account of the circumstances leading to the discovery of the trichina, and his conclusion is, that the honour is to be awarded to English anatomists. Professor Owen first described and named the flesh-worm, and first interpreted its true nematoid nature. But Mr. Paget, with Mr. Brown and Mr. John Bennett, probably saw the worm before Owen, and the last-named authority admitted Mr. Paget's priority to this extent. Mr. Wormald had, however, more than once previously noticed (no doubt while he was Demonstrator of Anatomy at St. Bartholomew's Hospital), the characteristic specks in the bodies of subjects brought for dissection, and he transmitted to Owen the actual specimens from which the discovery was made. Mr. Hilton, of Guy's, was the first to suggest the parasitic and animal nature of the specks observed in human muscle, and anticipated Wormald in his observations on dissecting-room subjects. Dr. Hodgkin states that Mr. A. Peacock observed these little bodies in 1828. Then, in reference to the German authorities, Leuckart denies the statement that Niedemann was the first discoverer of the specks. Herbst was the first to rear muscle-flesh worms in animals by experiment. Leuckart was the first to offer a correct solution as to the source and genesis of the flesh-worm; and Zenker was the first to demonstrate that these parasites were capable of giving rise to a violent disease in the human body. All which, we submit, is far more in place in the columns of a medical journal than in those of the *Pall Mall Gazette* or the *Times*.

THE SUPPLY OF MEDICAL NECESSARIES IN THE TIVERTON UNION.

We learn from the *Tiverton Gazette* that some difference of opinion exists between the Board of Guardians, or at least a portion of the Board, and their Medical Officers, on the subject of the supply of necessaries to the sick poor, and we regret to find Mr. Gulson, who it appears is the Poor-law Commissioner for that Union, giving utterance to opinions, and laying down regulations, which are not only derogatory and insulting to the medical profession, but are likely to lead to serious inconvenience, if not positive danger, to the sick patients. He is reported to have stated that in case of necessaries being required for the poor, the Medical Officer had no right to supply them, or to insist on their being supplied, and that his duty was confined to reporting the cases to the Board! Now, if this dictum be correct in point of law (which we very much doubt), a case of puerperal hæmorrhage, or of imminent collapse from some other cause, might be lost while the Medical Officer was going through the formality of applying for necessaries to the Board, which in most, if not all Unions, sits once a week, and in some only once a fortnight. We should recommend an application to be made to the Poor-law Board at Whitehall, against this monstrous doctrine laid down by the local Inspector, and as Dr. Edward Smith is now the Medical adviser of the Board, he ought to be consulted in the matter. As we believe that the Poor-law Board, especially at the present time, would investigate the subject if it was laid before them, we refrain from noticing at present the impertinent remarks made by some members of the Board in reference to the Medical Officer, and which were as unjust as they were offensive.

THE ARMY AND NAVY MEDICAL SERVICE.

WHEN publishing last week the Recommendations of the Committee upon the Rank, Pay, and Position of the Army and Navy Medical Officers, we stated that the appearance of the document was somewhat premature, inasmuch as it had not received the sanction of the authorities to whom it was addressed. This statement was correct, and we must repeat that the recommendations are not yet finally adopted; but we cannot believe that the Horse Guards and the Admiralty will oppose themselves to the concessions now proposed, and thus run the risk of augmenting the dissatisfaction which has so long existed among the Medical Officers of the two services. While congratulating our brethren of the Army and Navy on the prospect of their improved condition, it seems that very little thanks are due to the medical heads of those departments for their co-operation in redressing the grievances complained of; and indeed it is hinted that the chief obstruction to the measures proposed by the committee originated from some of those who ought to have advocated the claims of their brethren. It is stated that the combatant branches of the two services have been and are exceedingly well-disposed towards the Medical Profession, and that if the heads of the Medical Departments had done their duty the recent agitation would have been unnecessary.

THE BRITISH MEDICAL ASSOCIATION.

THE next meeting of the Association will probably take place at Exeter, as an influential deputation has waited on the Mayor to request him to invite the Association.

HOUSE OF LORDS.—FEB. 27TH.

LORD GRANVILLE, in answer to questions addressed to him, stated that an inspector had been sent into Northamptonshire to inquire into the outbreak of small-pox among sheep in that county, and that the Custom-house authorities adopted the same precautions with regard to sheep arriving from abroad as in the case of cattle imported into this country.

CATTLE PLAGUE BILL.

Lord GRANVILLE, in moving the second reading of the above Bill, declared himself unable to defend either its principle or its details. At the same time he admitted that some of the clauses would usefully supplement the Cattle Diseases Bill, and therefore he proposed the second reading with a view to the details being carefully considered by a Committee.

The Marquis of BATH thought the period to which the operation of the Bill was limited was too short to be productive of much good.

After a few remarks from the Duke of BUCKINGHAM and Lord ROMNEY, the Bill was read a second time, and was subsequently referred to a Select Committee.

HOUSE OF COMMONS.—FEB. 22ND.

SHEEP INFECTION.

Sir J. C. JERVOISE asked the Vice-President of the Committee of the Council on Education whether, in view of the Order in Council of the 4th of July, 1865, and also of the Order of the 19th February, 1866, relating to "sheep-pox or variola ovina," his attention had been given to the Eighth Report of the Commissioners of Her Majesty's Customs, in which that disorder was termed "scab or variola ovina," the first name implying a disease not uncommon in this country, and very easily cured; and whether he had noticed, in the same Report and page (26), that mention was made of "diseases which are sometimes erroneously supposed to be peculiar to foreign cattle, but which in reality had existed in the United Kingdom many years before the importation of foreign animals commenced.

Mr. BRUCE replied that he could not believe that the Commissioners really intended to say that "scab" and "variola ovina" were synonymous. The opinion expressed in the latter part of the question was a very safe and very possibly a sound one. But from whatever places they came they were now seated in the country. Whether the rinderpest or the variola ovina were imported or not seemed a matter of little importance. The vital questions were, were they contagious, were they likely to spread, and what were the precautions to be taken against them? Precautions had been taken. Out of seventy sheep lately imported from Copenhagen to Hampshire eight had the variola ovina, and of a neighbouring flock ten had died and ten were suffering. The district had been isolated.

FEBRUARY 23RD.—DISEASE AMONG SWINE.

Sir J. WALSH asked whether the attention of Her Majesty's Government had been drawn to the appearance of a new disease affecting swine in parts of the continent of Europe, and not only destroying the animal, but rendering the flesh poisonous and dangerous to human life?

Mr. BRUCE said that in 1862 Professor Gamgee was directed to report upon the subject of diseases in meat, and among the diseases embraced in the inquiry was the one referred to. A German physician of eminence who had paid special attention to the subject was directed to make a report, and it was published in the last volume of the reports of the Medical Officer of the Privy Council.

FEB. 26TH.

NAVY ESTIMATES.

In moving these estimates Lord CLARENCE PAGET passed a high eulogium on the medical officers of the navy. He referred to the labours of the Committee appointed by the Duke of Somerset, and to the services rendered on that Committee by two eminent medical men—one a member of the College of Physicians, the other

of the College of Surgeons. "I am bound," said Lord C. Paget, "to say that both these bodies have given us their most cordial assistance with a view to put the medical officers of the navy in such an improved position as that, while no unreasonable demand shall be made on the public, greater inducements than heretofore shall be offered to tempt them to enter the navy."

MARCH 1ST.

CATTLE PLAGUE EXPERIMENTS.

Mr. SANDFORD, in rising to ask the Secretary of State for the Home Department why the experiments made as to the cure of the cattle plague had not been laid upon the table of the House, said that the country had been told that the "stamping out" process was the only mode of eradicating the cattle disease. This, he thought, showed a very retrogressive tendency on the part of medical science, and especially in its veterinary branch. For the sake of the agricultural interest generally he sincerely hoped that the disease was not so incurable as it was represented to be, because, as they could not prevent importation of foreign cattle, they would always be liable to the recurrence of the disease. For himself, he was one of those who held the opinion that all the pestilences which visited us were more or less amenable to medical treatment; and it was stated in the newspapers that the remedies employed by Mr. Worms had in many instances proved successful. He should very much like to learn the particulars of the experiments made by that gentleman, and it was, he believed, the duty of the Government to lay those particulars upon the table of the House at the earliest possible moment. The hon. gentleman concluded by asking the questions of which he had given notice.

Mr. T. G. BARRING could assure his hon. friend that the Government were fully sensible of the importance and interest attaching to the experimental treatment of animals affected with the cattle disease, and their attention was drawn to the subject at the very commencement of the outbreak in this country. As the House was aware a Royal Commission was appointed for the express purpose, among others, of inquiring into the mode of treatment likely to prove successful in the case of animals affected with the plague, and the Government thought it would be far better to intrust such an inquiry to one authority, instead of committing it to the care of two separate bodies. That commission had not neglected their duty. On the contrary, they had prepared a scheme of the most exhaustive character, giving to the world the most complete and accurate information with regard to the nature of the disease, the different modes of treatment, contagion, and other matters most interesting to the public and most likely to be attended with advantage on future occasions. These particulars were most fully detailed in the second report of the Royal Commission, which his hon. friend had probably not yet seen. He would find that not only many eminent veterinary surgeons, but also men of distinction in the medical profession, had been engaged in inquiries concerning the disease, and he would find certain general statements made regarding the result of the inquiry. The Commissioners stated that no remedy which had been discovered could be relied upon, that vaccination had not proved a safeguard, and that they purposed giving the public more details with reference to inoculation. In their third and final report the Commissioners promised to give full and complete accounts of the experiments which had been made, and the results of investigations which had been instituted by the medical gentlemen to whom they had been intrusted. Under those circumstances it would have been impossible for the Government up to the present time to furnish the House with complete information upon the subject. The third report of the Commissioners would, he believed, give some valuable additional information. [An hon. Member: "When will it be presented to the House?"] Of course the third report of the Commissioners would be presented as soon as it was made, and would then be laid upon the table of the House.

CLINICAL LECTURES

ON

DEEP-SEATED ABSCESS OF THE THIGH.

By JOHN K. BARTON, M.D., F.R.C.S.I.,

SURGEON TO THE ADELAIDE HOSPITAL, AND LECTURER ON SURGERY IN THE LEDWICH SCHOOL OF MEDICINE.

GENTLEMEN,—You are aware that chronic abscesses often present themselves in the thigh although originating at a distance. Psoas abscess due to caries of the vertebræ frequently points in the anterior part of the thigh, or passing backwards with the tendon of the muscle to the lesser trochanter, it may present posteriorly. Abscess also in connexion with strumous disease of the hip-joint, often presents in the outer or back part of the thigh. It is not to such cases I now wish to direct your attention especially, but to abscesses which originate in the thigh or popliteal space, and being deep-seated and bound down by strong layers of fascia, give rise to great constitutional disturbance, and frequently present peculiar difficulties of diagnosis as well as of treatment. Allow me to remind you of the intimate union which exists between the rectus muscle in front and the two vasti on either side, and how all are closely covered by the very strong enveloping fascia-lata; pus formed under this mass of anterior muscles would not give the sense of fluctuation to your fingers, but would perhaps pass on through the opening in the adductor magnus muscle into the popliteal space, where being very deeply seated, the true nature of the tumour would then be doubtful. Dupuytren's biographer relates as an instance of the diagnostic power of that great surgeon, his instant recognition of the true nature of a case of this kind. A man was brought to the hospital with a large swelling of the thigh; while others were examining disussing, imitating, Dupuytren touched the tumour, without a word took out a bistoury, passed it down to the bone, and gave exit to a pint of purulent matter. Now, gentlemen, before you imitate Dupuytren in the brilliant rapidity of his treatment, take care you make your diagnosis as sure as his was. Aneurism in the thigh or popliteal space, has many symptoms in common, very frequently, with the disease we are speaking of—it has been mistaken for it, and may be again. The terrible mistake of plunging a knife into an aneurismal tumour has actually occurred, and the most experienced surgeons are the most cautious in pronouncing upon the nature of a deep tumour in this region. I hope, however, to show you that by a careful attention to the symptoms you may form a sound opinion in any case, and your treatment may be as sure and safe, if not as dashing, as the illustrious French surgeon's. In illustration of the points upon which you should rest your diagnosis, I will relate two cases:—

Case 1.—John Purdon, 28 years of age, a servant, was admitted into the Adelaide Hospital upon the 3rd of last January, with a swelling of the left thigh; it occupied the lower third of the inner surface of the thigh, and extended into the popliteal space, the hollow of this space being partly filled up, and pressure into it causing pain. Pressure upon the surface of the tumour in the thigh also caused very acute pain. The tumour was pale; no distinct edge could be felt circumscribing it; no pulsation could be felt or bruit heard in it; at one point about two inches down the inner side of the knee-joint, an

indistinct sense of deep fluctuation was perceptible. The femoral artery beat naturally; the popliteal could not be felt on account of the swelling in that space, and after a careful examination the posterior and anterior tibial could be distinctly felt, the foot only being œdematous, rendered it difficult to settle this point; the leg was kept flexed on the thigh; the patient's countenance was very pale and anxious; pulse 112. The history he gave of his disease was briefly as follows:—Six weeks before his admission to hospital he was seized with headache shivering; next day he observed an erysipelatous blush on the left leg, below the knee, which, however, disappeared in a day or two, but was followed by a painful swelling in the lower and inner part of the thigh, which had gone on increasing in size for about three weeks. He had been suffering acute pain for at least a fortnight, and was very anxious to have something done for his relief. The diagnosis of this tumour was, deep-seated abscess of the thigh, extending into the popliteal space; the symptoms which showed it not to be aneurismal was—

- 1st. The pulsation of the arteries of the leg.*
- 2nd. That the chief part of the swelling was not over the course of the vessel.

Concluding it not to be aneurismal, the other symptoms made the probability of its being an abscess almost a certainty, I will take up this case again, but now compare the symptoms with those present in the following:—

Case 2.—Martin Kinsella, 24 years of age, a shoemaker, of intemperate habits, was admitted into the Adelaide Hospital, in October, 1863, with the right foot and leg swollen and œdematous, and complaining of severe pain from a swelling in the popliteal space. Eight weeks previously he was attacked by severe pain behind the right knee, which extended down the entire of the leg as far as the outer malleolus; this pain was constant, but was rendered worse by exercise, and he said increased at night. About a fortnight after he first felt the pain he noticed a swelling in the popliteal space, which was soon followed by the œdematous state of the foot and leg. He says that the swelling at no time suddenly enlarged; he received no injury whatever; at first his general health did not suffer, but latterly he feels very sick, the pain has kept him awake at night, being frequently obliged to sit up all night to relieve it. Upon proceeding to examine the limb I found it in the following state:—The popliteal space was completely filled up by an undefined swelling, which gave a sense of deep-seated fluctuation to the fingers; the skin covering it was of natural colour, no thrill or pulsation whatever could be felt, nor with the stethoscope could anything be heard; the limb from the knee down was œdematous. Neither the anterior nor posterior tibial arteries could be felt pulsating, and the femoral when examined in Hunter's canal, could scarcely be felt at all; the pulsation of the artery higher up was pretty full.

The diagnosis lay between abscess and aneurism. In favour of the former was the sense of fluctuation, and the absence of all bruit, pulsation, or thrill; in favour of the latter was the fact that the arteries below the disease had ceased to pulsate, and that the artery immediately above pulsed indistinctly.

The further history of this interesting case showed it to have been a diffused aneurism, whether originally from rupture or disease of the artery was doubtful. For our present purpose it is only necessary to remark, regarding the further progress of this case, that in a day or two a second swelling began to form to the outside of the knee-joint, evidently communicating with the one in the popliteal space, and giving an obscure fluctuation, and upon the following day some degree of thrill and pulsation was discovered in the popliteal swelling.

Comparing the symptoms at the time of their admission with the cases, you remark that while the appearance and

* The œdematous state of the leg and foot showed that the pressure of the tumour was sufficient to retard the venous circulation very materially, but had this pressure come from an aneurism the arteries could not be felt beating.

feel of the tumours were almost quite the same, the unimportant difference was the state of the arterial circulation in the two limbs. In the case of aneurism this was very decidedly interfered with, while in the case of abscess it remained natural. You may look on this as the most important point in making the diagnosis in a difficult case. If the arteries below the tumour, after a very careful examination, cannot be felt to pulsate, the case is probably one of aneurism; whereas if they can be felt pulsating naturally, and the same as the arteries of the other limb, the artery is not implicated in the disease.

Is there any other disease which you might mistake a deep-seated abscess of the thigh for? I believe soft or medullary cancer, if developed in the deep spaces of the thigh, would, as far as the mere feel of the tumour, be quite undistinguishable from an abscess. The sensation given to the fingers by this soft substance, when bound down by a strong fascia, is precisely the same as that given by fluid. So you must not depend in this case either very much on the feeling of fluctuation, but take other circumstances into account before you decide. The state of the lymphatic glands and the character of the constitutional disturbance will be important considerations.

(To be continued.)

THE MEDICAL USES OF CHLOROFORM INHALATION.

By CHARLES KIDD, M.D., M.R.C.S.E.

THE medical uses of chloroform, or rather its administration, in purely medical, as contradistinguished from ordinary surgical cases, begins to assume a form of very considerable interest and importance, not so much as an agent capable of removing mere pain in neuralgia or simple spasm, as in controlling the more dangerous serious forms of disease, such as infantile or puerperal convulsions, where life is at stake, or as a remedy also (perhaps only auxiliary) of great usefulness, nevertheless, in various forms of epilepsy or epileptoid affections, though this anæsthetic is not so effectual or safe in simple hysteria, delirium tremens, or chorea.

The medical uses of chloroform, in a word, as I believe, have not been recognised sufficiently in our periodic literature, its far wider and more brilliant help or aid to the operating surgeon (without which, indeed, he could now do little), having eclipsed its desultory application in the wards of the physician, or by the bedside of the midwifery patient in her hour of anguish and agony, where it has proved to be almost a greater boon than in the experimental and gigantic operations of the surgeon.

And, firstly, reference may be made to cases of puerperal convulsions. All the best obstetricians now agree that whether we have albumen in the urine or not (that great bug-bear of practice), the skilful administration of chloroform seldom fails to afford relief, and by its means we may dispense with the excessive venesections that so weaken such patients in former times.

In cases of severe agony attending the passage of gall stones the cautious inhalation of a drachm or two of chloroform will often act like a sudden charm in affording relief from pain and spasm. It is probable that in such patients there is produced a relief of pain, with relaxation of the distended gall duct, associated nervous fibres of the diaphragm, duodenum, &c. (all thrown into spasm by an irritating calculus). It is curious, too, that jaundice so occurring is cured, and jaundice has also been occasionally produced by the same agent, the latter a much more rare phenomenon than the former.

A case of the following kind has come under notice:—An old gentleman in the higher circles of society, subject to bad attacks of "jaundice and gall stones" in the country, was declared at the point of death from black jaundice and his old enemy, gall stones; an entire week of horrible

agony had been experienced. Blisters, warm baths, purgatives, globulistic remedies, &c., had all been tried, and tried in vain. Opium in large doses had made things worse, and blisters with emetics no better. A fair trial, in one word, was given to the good old stereotyped abracadabra of Copland and Watson, that

"Old experience, which doth attain
To something of prophetic strain,"

could advise no further, and further experience had been summoned from the nearest country town. All in vain; it had been well reasoned out that the case was incurable; that the bile secreted by the hepatic cells had regurgitated along the cystic duct into the gall bladder; how there stored up it became concentrated and inspissated; how cholesteine (not Dr. Thudicum's blood corpuscles) had formed a calculus with much more, but all pointing to a sadly established organic disease of the worst kind. In this emergency an eminent city physician was summoned by telegraph, a man of the new school, eclectic, glad to adopt remedies from whatever side of the compass they may come. "Have you tried chloroform."

"Nothing like leather! of course not, but perhaps you would not be afraid of the risk."

Such the question and reply in consultation, but a few drops of chloroform relieved the patient of his agony, the gall stone passed as if by some potent spell, and a beautiful cure was the result.

In some of the worst sufferings of uncomplicated asthma and in whooping cough I have known the inhalation of chloroform vapour prove beneficial beyond expectation; indeed, it is clear that in the often vaunted popular cures of whooping cough, where children inhale the vapour at gas works, the cure is only to be explained by the calming influence on the larynx and glottis of some of the many gaseous carbo-hydrogen belonging to coal gas, so like ether vapour. I have known several times the popular amber oil liniment for whooping cough to prove far more effectual when chloroform and ether were substituted for the oil of amber, the liniment rubbed to the chest and neck, rather than in the time-honoured method to the spine, thus allowing the chloroform to be inhaled. The direct application of nitrate of silver to the glottis, so specific in whooping cough, is also facilitated by this practice.

Again, in various forms of epilepsy, chloroform in full doses not only controls the fit, but acts as an admirable auxiliary in allowing a full examination and cauterization of the peripheral seat of the origin of the disease. Hundreds of such cases have now been cured. Chloroform, however, is not so safe in hysteria or chorea or the debility of delirium tremens, while in all the other affections just detailed, and many more, it seldom fails to give most beneficial results.

Sackville-street, London.

CONGENITAL SYPHILIS AFFECTING THE BONES.—At a meeting of the Medical Society of Vienna, Dr. Firth stated that he had examined the body of an infant, which at the age of eight days had been admitted into the foundling institution with a maculo-pustular syphilitic eruption on the feet and hands and on other parts of the body. The mother was healthy. The arms hung loose; but, as paralysis of the extremities frequently accompanies congenital syphilis, this condition excited no surprise. On closer examination, however, there was found an abnormal mobility of the shoulder-joint, and crepitation was distinctly heard: sometimes, however, it disappeared. The child died at the end of five days. On post-mortem examination, the humerus was found necrosed, and its epiphysis separated. The end of the epiphysis next the humerus was also eroded and rough: and hence arose the crepitation, the occasional disappearance of which was due to the intervention of ichorous fluid between the epiphysis and the shaft of the bone.—*Wiener Med. Wochenschr.*

At Trowbridge, in Wiltshire, a disease has broken out amongst the fowls. "They are affected with spasms, a yellowish mucus runs from their beaks, and their combs turn black."

CASE OF
 IMPACTION OF A PLATE OF ARTIFICIAL
 TEETH IN THE PHARYNX
 DURING A PERIOD OF FIVE MONTHS.

By Dr. GEOGHEGAN,

ONE OF THE SURGEONS OF THE CITY OF DUBLIN HOSPITAL, ETC.

THE following case, in which a large plate containing artificial teeth lay impacted in the pharynx, *apparently without the cognizance of the patient, during a period of five months*, seems deserving of being placed upon record.

About a year since, a gentleman, 60 years of age, and previously healthy, who had presented his son at my house for surgical advice, requested me, before leaving, to inspect his own throat, which, his friends feared, was about to become the seat of cancerous disease.

I learned, that five months previously he had been seized, *whilst in bed*, with difficulty of deglutition and of breathing, a sensation as if a bit of rough cane were moving up and down in his throat—efforts to vomit, and copious flow of muco-salivary fluid from the mouth; he found that liquids and pulpy matters could be swallowed, but that the deglutition of solids had become impossible. Matters had so continued up to the period at which I was consulted. He now evinced slight hoarseness, and there was unusual fullness, with increased breadth externally, in the situation of the base of the tongue and of the pharynx. The foreign body could not, however, be defined from without. The patient further stated that the salivation, which had continued from the first, was variable in amount—sometimes nearly subsiding, and again breaking out anew. Great relief was obtained during the exacerbation, from the application of a blister to the neck.

An experienced and careful practitioner who was called in at the time of the occurrence was informed that no cause except "cold" could be assigned in explanation of the above-named symptoms. Being unaware that a plate of false teeth (constructed so as to supplement an interrupted range of natural ones) had been habitually worn and the patient himself not having volunteered any statement upon the subject, the greatest difficulties were thus obviously interposed in the attempt to estimate the real nature of the case.

On inspecting the fauces I could discover nothing more than the increased vascularity so commonly observed in the throat of an habitual smoker. Passing my finger well down to the epiglottis, I at once encountered an hard body, which, on further examination, was found to traverse the entire breadth of the pharynx, and to have become impacted there, owing to the entanglement of its sharp and projecting extremities in the opposite sides of the canal. The sharper and tooth-like end lay to the right side, and both were situated at a much higher level than the centre. A curved catheter wire, when caused to strike the foreign body, elicited a clear ringing sound.

I then proceeded to inspect the parts with the laryngoscopic mirror. The epiglottis was seen standing erect and red, but not swollen; the anterior portions only of the aryteno-epiglottidean folds were discernible, whilst the arytenoid cartilages were concealed by a dusky-red body streaked with grey. The true vocal cords were, of course, invisible.

An attempt to move the foreign body caused efforts to vomit, spasmodic cough, and the ejection of abundant mucus, tinged with blood of an arterial tint.

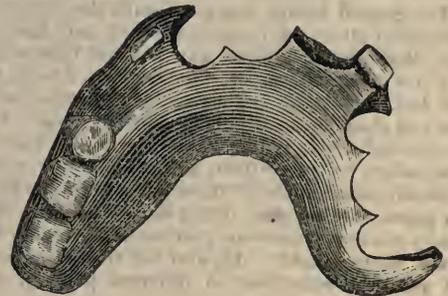

With the above phenomena before me, I inquired whether at any of the meals more immediately preceding the supervention of the symptoms just described, he was conscious of having swallowed any hard or unusual substance? To this he replied in the negative; but then, apparently for the first time, recalled the fact, that on rising on the morning following the occurrence, he had *missed his tooth plate*, and stated, that having then imagined that it might have dropped into the urinal and been thrown

out by his servant, he had dismissed the matter from his mind.

The cause of the mischief thus stood revealed.

Having explained to the patient the risks that might be expected to attend on the manœuvres requisite for extraction, and more particularly that of hæmorrhage (in the event of the pointed ends of the foreign substance having already caused partial ulcerative penetration of an adjacent vessel), I proceeded to operate.

In the first place, I attempted to disengage the ends of the plate by hooking my forefinger on each alternately, exercising at the same time a moderate and cautious traction. I next tried to draw it upwards, having passed a stout and well-curved catheter-wire beneath its centre. This measure, I thought, caused the body to yield slightly. I then again attacked the corner of the plate with the finger. Lastly, I passed a common polypus (nasi) forceps through a chasin in the upper alveolar ridge at a point to the left of the median line, where two incisors were wanting. Grasping the centre of the plate, I employed slow and careful traction, combined with slight rotatory movements (and aided by occasional use of the finger at its points). This final manœuvre was happily crowned with success.

The plate, as seen in the accompanying woodcut, proved to be of hardened gutta-percha, coloured red, and felt light for its size. Its circumference was sharp, as were also its horns.

Its extreme breadth was 2 5-16th inches. Its maximum depth at centre, 13-16ths of an inch. It weighed 121·7 grains, and included five artificial teeth, and niches for five natural ones. Its concave mouth-ward aspect, placed downwards, had lain on the upper part of the arytenoid cartilages, and partly on their posterior surfaces. Its palatine face had presented upwards and backwards, and was speckled with greyish mucus.

The removal of the offending body was speedily followed by disappearance of the chief symptoms. Even at the date of the present communication, however (seventeen months since the accident), uneasiness is still felt at the right side of the neck at a point corresponding to the cricoid cartilage, and solid food, unless very well masticated, and in small volume, requires to be washed down by a mouthful of fluid.

Accidents arising out of the casual displacement of a tooth-plate are not uncommon. I believe, however, that few cases are on record in which the accompanying circumstances, and more especially the forgetfulness or reticence of the patient, were more calculated to embarrass a practitioner than in the one now submitted. Mr. Hilton* (a true "conservative" surgeon and profound student of *Nature's* operations), has recorded a case in which he removed a tooth-plate by œsophagotomy with success. In some instances such bodies have passed into the stomach, and when not very large or not beset by sharp projections, have been discharged by stool after variable intervals. Such a result must be considered rather a rare and fortunate one. On the contrary, when detained in the

* Guys' Hospital Reports.

œsophagus, the foreign body has been known to ulcerate its way even into the left pleura. Very voluminous bodies may reach, and even safely traverse, the stomach, but are subsequently arrested with resulting fatal mischief. In the Museum of the Royal College of Surgeons, there is deposited a preparation which exhibits a tablespoon that had been swallowed by an adult Innatic. It reached the duodenum, where it caused a perforation of the bowel.

AN AGGRAVATED CASE OF NEURALGIA SUCCESSFULLY TREATED WITH "CORRIGAN'S CAUTERY."

By JAMES C. HAYES, M.D., L.R.C.S.I., &c.

THE following case of neuralgia was under my treatment for a considerable time, and after having nearly exhausted the resources of the materia medica, I was obliged to have recourse to the "cautery," which I am glad to report realised my best wishes.

The Rev. J. B.——, aged 58, of the bilious-nervous temperament, active mind, and very regular habits, was never a sound sleeper, and if awoke in the middle of the night found it very difficult, often impossible, to sleep again. The general health was good, with the exception of an occasional attack of dyspepsia, which only lasted a few days, disappearing without any medical treatment; has had a few light attacks of "lumbago." About the middle of last summer he felt an aching sensation in his right arm and shoulder, as if the muscles were hurt; this uneasiness lasted about ten or eleven days. On the 8th of last December, he was without any premonitory symptoms, suddenly seized with a "darting" pain in the right arm, at a point corresponding to the insertion of the deltoid muscle, gradually increasing in severity until it became almost insupportable. He also felt transitory tingling and pricking sensations in different parts of the arm.

To relieve pain, he was locally applying a rubefacient liniment containing sp. turpentine, which caused abrasion of the cuticle, and aggravated his suffering.

On the 17th December I was requested to visit him; saw him in bed, he complained of violent pain, which appeared to be seated in the circumflex and musculo-spiral nerves; he was very restless, having had no sleep the five previous nights; anxious countenance, the tongue was clean, bowels regularly moved without the aid of any medicine, the urinary secretions were healthy, skin cool, and pulse natural. There was nothing abnormal in the appearance of the arm, nor did pressure made over the affected part produce any effect. I directed the arm to be stupefied with chamomile flowers and poppy heads, to be repeated in the course of the day, and the following liniment to be rubbed in often:—

℞ Lini. saponis, ℥viii.
Tr. aconitæ, ℥vi.
Tr. opii, ℥ii.

M. Fiat linimentum sepe utend.

To procure sleep I ordered gr. x. of pulv. Doveri to be taken at bedtime.

18th: Had four hours sleep last night, has not much pain. Repetatur pulv. Doveri.

19th: Had no sleep last night; arm very painful. I continued the local treatment, ordered an aperient composed of pil. colocynth co. and pil. hydrarg., and increased the quantity of pulv. Doveri, to be taken as usual.

20th: Had no sleep last night; arm still painful. As the pulv. Doveri had not the desired effect, though the dose was increased, I ordered two draughts of the Tr. henbane, one to be given at bedtime, and the other a few hours after, if necessary.

21st: Had no sleep last night; took the two draughts; arm continues painful. I ordered a mixture of iodide kal., gr. viij. to the ounce, two tablespoonfuls to be taken three times a day. He continued much the same way up to the 24th, when I saw him in consultation with my

brother, Dr. F. Hayes of Shanagolden. We ordered the following liniment for the arm:—

℞ Lini. camphoræ, ℥viiij.
Tr. aconitæ, ℥vi.
Chloroform. ℥vi.

M. Fiat linimentum, to be used three or four times a day.

The iodide kal. mixture to be repeated, and as the draughts did not induce sleep, we ordered the following sedative mixture:—

℞ Aquæ acetatis ammoniæ, ℥iij.
Muriatis morphiæ, gr ii.
Pulv. ipecac. gr. ix.
Syrupi aurantiae, ℥ss.
Aquæ, ℥viiss.

M. Fiat mist. sumat. coch. amp. tertia quaque hora. We also repeated the pil. colocynth co. and pil. hydrarg. He is taking his ordinary food all along, consisting principally of bread, butter, and tea for breakfast, roast meat for dinner, with a liberal allowance of wine; his appetite is very little diminished since the commencement of his illness.

25th: Had no sleep last night, but got great ease from pain. After having taken a few doses of the mixture, it produced vomiting, when its further administration had to be discontinued. At five o'clock in the evening I commenced giving him half a grain of pulv. opii every second hour, and continued it without intermission until he had taken three grains and a half, when he objected to its further use. It did not produce sleep, but abated the intensity of the pain considerably.

I may here remark that he had from the commencement a great objection to opium, and requested not to be narcotised until I prevailed on him, and as I feared or anticipated the opium would fail, successive measures that were likely to afford relief were clearly indicated, but some delay necessarily occurred in having to send to Dublin for these, and in one instance an accident occurred which prevented their being at hand.

26th: Though having no sleep last night, he is apparently under the influence of the opium. I now ordered two grains of sulph. quinine, to be taken night and morning, iodide kal. mixture to be continued, and liniment to be rubbed on as before.

27th: Had two hours' sleep last night; arm still continues painful; during the past two days he feels a tingling sensation in the digital branches of the median and musculo-spiral nerves.

28th: Slept an hour and a half last night; arm painful.

31st: Had no sleep the two previous nights; arm painful. The pain is almost unendurable, and appears to be permanently fixed in the circumflex and musculo-spiral nerves; the tingling continues in the fingers. As neither the potash, quinine, opium, alterative pills, nor liniment had any beneficial effect, I determined to inject the solution of the muriate of morphia under the skin. Having procured a hypodermic syringe, I injected one-third gr. of the muriate of morphia through two punctures in the most painful part of the arm. He experienced almost instantaneous relief from pain, felt drowsy, and went to sleep very soon.

January 1st: Had four hours' sleep last night. The pain returned to its old habitat this morning, but not so severe as before the operation; it, however, gradually increased in severity towards evening, when I repeated the operation, using the same quantity of morphia.

2nd: Had no sleep last night; arm painful. At eight o'clock in the evening, I injected half a grain of the morphia; it diminished the violence of the pain; "felt as if electric shocks were sent through his body."

3rd: Had two hours sleep this morning.

4th: Had about two hours sleep last night; arm painful.

7th: Had no sleep the two previous nights; arm painful.

8th: Had very little sleep last night; arm very painful. The agonising pain continuing in the arm and getting

scarcely any sleep, the potash and quinine which he is taking all along having no appreciable effect on the disease, the hypodermic method not having the desired effect, I resolved to apply "Corrigan's Cautery." Having obtained one from the Messrs. Fannin, Dublin, I applied it in the usual way to the antero-posterior surface of the arm, commencing at the top of the deltoid and terminating within two inches of the elbow-joint. The pain caused by the operation was pretty smart and severe.

9th: Slept an hour last night; the arm is not more painful than before the application of the "Cautery." I ordered lini. camphoræ to be rubbed into the arm.

10th: Had two hours sleep last night; is not able to distinguish the pain produced by the "Cautery" from that which is neuralgic. It is quite evident to-day that the "Cautery" has produced a decided impression on the disease, the agonising pain which hitherto appeared to be fixed on the circumflex and musculo-spiral nerves is now confused with that caused by the "Cautery," and a uniform soreness is experienced in the arm.

12th: Had two hours sleep last night; does not feel the original "darting pain;" the tingling in the fingers continues.

15th: Slept last night; arm not painful. He continued to progress steadily and rapidly, and when the irritation which was occasioned by the "Cautery" subsided, the original intolerable pain was gone; nothing remained but a slight tingling of the fingers, which disappeared altogether at the end of January.

Rathkeale, county Limerick, March, 1866.

LOCAL ANÆSTHESIA IN DENTAL OPERATIONS.

By FRANCIS McCLEAN, Junior,
DENTAL SURGEON TO THE CITY OF DUBLIN HOSPITAL.

THE following cases, in which dental operations were performed under the influence of "Richardson's apparatus," are, I think, of some interest at present, and they are therefore published rather with the view of recording the results of an experimental employment of the instrument in this branch of surgery than with any suggestion in view. The instrument has been employed with the best result in the minor operations of surgery, as reported by Dr. Gascott Symes in THE MEDICAL PRESS AND CIRCULAR; but a natural impression exists that it is less applicable to tooth extraction than to other operations on account of the pain anticipated from the congealing process. The following cases, I think, prove that this objection to its use is not well founded, and that where the spray can be satisfactorily applied, it is an agent of great and lasting importance to the profession:—

Case 1.—A nervous man, age 30; second inferior molar, right side; pain most severe when applying the spray, which I did for about thirty seconds; on pushing the forceps down on the neck of the tooth nothing was felt, but when detaching the tooth from its connexions with the socket (which required considerable force) the usual pain was experienced; in one second after the tooth was out no uneasiness whatever was complained of.

Case 2.—A medical man; second inferior molar, right side; the surrounding parts in a high state of inflammation; patient had no discomfort when applying the spray, but was inclined to cough; the tooth was removed without requiring much force, and nothing was felt; in a few minutes after the tooth was out the pain was violent.

Case 3.—A lady; never had a tooth extracted. I applied the spray for something less than a minute, and extracted the first left superior molar. Afterwards she told me she suffered very little pain, and that the spray produced none. After some minutes the pain was violent for a short time.

Case 4.—A stout female; first superior molar, left side, with a large cavity in it, and very firm. Spray applied for thirty seconds, which caused slight pain, and she

describes the sensation during extraction as "a slight touch;" some pain afterwards on return of circulation; very little hæmorrhage.

Case 5.—A young girl; stumps of a second inferior molar; tooth broken in former operation; very unmanageable; the stumps low down. In this case it was impossible to apply the double jet, so I tried the single one; the moment I applied the instrument to extract, the patient commenced struggling and crying out; with difficulty and pain one was removed.

Case 6.—A medical student; second right superior bicuspid, had never lost any permanent tooth on that side; very slight pain when freezing; none at all on extraction or subsequently.

Case 7.—A young man; second inferior molar, right side, very carious; application of cold slightly painful, but not nearly so bad as the removal of teeth on former occasions; no pain on applying the forceps, when unfortunately the tooth fractured, and it was necessary to remove the fragments separately, which I did after a good deal of pain. This same gentleman, for the benefit of the class, allowed me to extract a superior bicuspid which was carious, and states he felt no pain whatever either on freezing or extraction; he did not know when it was out.

Case 8.—A medical student, very nervous man, second inferior molar, left side; could hardly bear me to touch it. On placing cotton wool in its cavity pain was intolerable for some minutes. He did not mind the cold of the spray after the first dash of it. When I was removing the tooth, he describes the feeling to be as of something pushing at it, but had no uneasiness.

In the first case the pain, on application of the spray, was, I have no doubt, caused by the cold coming in immediate contact with the nerve of the tooth through the pulp cavity, which was exposed, and at the suggestion of my friend, Dr. Geoghagan, I first place a small piece of cotton wool in the cavity of the tooth, and with beneficial results. The subsequent pain in the second and third cases, I believe to have been caused by the patient's taking warm water into the mouth before the frozen parts had time to come back to the normal temperature.

The conclusions which I have myself arrived at are:—

1. That if the nerve be properly protected from the immediate contact with the ether spray, the freezing process is attended with little, if any, discomfort.
2. That the anæsthetic effect is complete whenever the spray can be properly applied, but that this essential cannot be satisfactorily attained whenever the operation occupies a longer period than about a minute. The apparatus is, therefore, only partially applicable to the removal of stumps.
3. That the gradual restoration of the circulation in the gum causes no pain, but that the usual wash of tepid water is objectionable as causing too sudden a change of temperature.
4. That as far as my short experience extends, there is no danger of the sloughing of the gum, which has followed the use of the ordinary congelation apparatus.

I have this morning seen four of the cases operated on in the hospital by me last Thursday, and am glad to say there has been no uneasiness since, so that I do not apprehend sloughing of the gum. The instrument I have used in the above cases was Dr. Richardson's anæsthetic spray-producer, supplied to me by Messrs. Fannin and Co., and anhydrous ether.

I have recorded all the cases just as they occurred, not confining myself to the successful ones, that the readers of THE MEDICAL PRESS AND CIRCULAR may judge for themselves.

CHOLERA AT BREST.—The *Ocean* of Brest, of Feb. 12th, states the deaths from cholera during the five preceding days amounted to forty-six, including thirteen in the hospitals. The epidemic has nearly ceased within the walls of the town, the deaths having diminished from seven to three or four per day, almost all outside the walls.

Foreign Medical Literature.

ON THE PATHOGENY OF CYSTOID KIDNEYS.

By W. KOSTER.

(Continued from page 240.)

Translated from the *Nederlandsch Archief voor Genees- en Natuurkunde*, 1e Deel, 2e Afl. Utrecht, 1864, for THE MEDICAL PRESS AND CIRCULAR.

By WILLIAM DANIEL MOORE, M.D. (Dub.), M.R.I.A.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS, OF THE NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

c.—Theory of renal cystoid in adults as a disease of involution.

To the pathogeny of a morbid process belongs not only the investigation of the series of anatomical changes in tissues or organs, whereby it has become what we find it in the stage of complete development, but also the knowledge of the condition of body and of the period of life at which it appears. The condition of body depends on two factors—namely, the ordinary “physiological” changes according to the necessary course of the metamorphosis of matter during the consecutive periods of life, and the influence of accidental “abnormal” effects, whereby important modifications arise and morbid processes may be excited, which might otherwise appear not at all, or under a totally different form. Thus etiology and pathogeny meet together so soon as we possess a perfect knowledge of a morbid process. Complete acquaintance with the first, is indispensable for the second, understood in its most ample sense.

If experience assigns to a definite morbid process a place in a certain period of life, to which it, with slight modifications, is connected, we have obtained an important etiologico-pathogenetic element.

With these principles before our eyes, we call the renal cystoid a disease of involution, and reckon it therefore among the processes which are peculiar to middle and advanced age. The possibility of its sometimes occurring between the thirtieth and fortieth year of life is not thereby excluded. The involution process is not a process which must necessarily arise after the sixtieth or seventieth year, but is one which in its essence depends on changes of involution, and then in general occurs in the period of those changes. Abnormal predispositions or accidental external circumstances might here produce modifications.

We see the same in a number of other processes. If we trace the pathogeny of an ordinary cerebral hæmorrhage, the changes in the brain lead us to the consideration of the condition of the vessels and of the heart. If we inquire further into the origin of these vascular changes we discover the existence of gradually developed hypertrophies of connective tissue in the walls, followed by softening and calcification of the altered spots. No one will hesitate to look upon these vascular alterations as senile conditions, as involution processes, and, moreover, the hæmorrhage of the brain dependent thereon as a disease of old age. Yet any one might, before his fortieth year, have atheroma of some arteries, and get an attack of cerebral apoplexy; or the process of vascular alteration leads through local stronger development, or, under other favouring circumstances, to an aneurism or to constriction of an artery, &c. Notwithstanding all these possible modifications, the atheromatous process remains an involution change, although it rarely occurs in its typical “physiological” condition, although even this type itself is not to be defined.

We might adduce yet other examples. In any one dying at an advanced period of life, of “marasmus senilis,” we shall, among other changes, find the liver and the kidneys atrophied, pale-coloured, sometimes granular on the surface. People speak correctly of a cirrhosis of old

age. But we see the same change occur in a still higher degree, also in morbid processes, for example, in the liver. The hepatic alteration, out of proportion to the other involution processes, early and highly developed (whether or not under the influence of abnormal external causes), may also occur at forty or fifty years of age, as a characteristic morbid process, which, if not the only, is yet the principal cause of the morbid vital phenomena.

Let us imagine, further, what modifications in the details of the processes alluded to may still occur. The arterial change leads in one case to colossal thickening of the walls; in another the wall is destroyed and perforated. Now, constriction, at another time dilatation, of the vessels occurs. In cirrhosis of the liver (both the senile form and that which constitutes an “independent” morbid process) sometimes the whole organ atrophies uniformly, and all parts, with the exception of the larger vessels and the connective tissue, diminish; in other cases we find sac-like cavities in the tissue, filled with a bilious fluid, whereby the jaundice sometimes occurring in cirrhosis is explained. The atrophic senile kidney now becomes at times smaller (by hyperplasia of connective tissue and subsequent shrinking), and exhibits no cysts; on other occasions we meet with numerous cysts in the atrophic kidneys.

This is not the place to speak farther of these differences. I would refer only to the possible (known and unknown) slight modifications in the alterations of tissue in involution and morbid processes, in order to make use of them in considering the origin of cystoid renal degeneration.

Our theory would therefore be briefly as follows:—As an essential morbid process in the liver (cirrhosis with biliary cysts) arises from an involution-process beginning early and running an unusual course—the renal cystoid arises from a modified involution of the kidney. While the latter in general leads to moderate atrophy of the whole kidney, under modified circumstances a greater hypertrophy of connective tissue occurs, with atrophy and calcareous deposition in the Malpighian pyramids, especially in their summits. If it be desirable to give the disease a fixed name, we may call it, *interstitial nephritis of the pyramids*.

It is remarkable, in connexion with this theory, that in four of the cases more accurately described by Rayer (see our statistical statements), the age of the patients amounted to 40 years or upwards. To these may be added an important case, communicated to me by my friend Boogaard, in which in a woman, aged 46, who died with uræmic symptoms, two enormously enlarged cystoid kidneys were found, in which scarcely a trace of renal tissue could be discovered. Of another case, in the *Collectio Brugmansiana*, at Leyden, likewise with most highly developed cystoid degeneration, the only mention of the kidneys made is, as Professor Boogaard has kindly informed me, that they belonged to a “homo adultus.”

The two other cases of Rayer, one of 30 and one of 29 years, afford less support to my theory. Of one of them I have already remarked that it was not a typical case, but was partly combined with tuberculosis; the other we must look upon as an instance of extraordinarily early involution process. If this case, of which the particulars were less accurately known, stood alone, we should leave it out of account, but there are other cases still, which constrain us not to insist too strongly on the above opinion in all instances. In the first place, that of Gluge [(p. 238), in which, however, no particulars, not even the age, are known; but especially that communicated by Beckmann (p. 238), of a girl aged 19, with apparently incipient cystoid degeneration, and “perfectly normal pyramids.”* Such cases invite us either to apply Virchow's explanation, that some forms of cystoid are to be regarded as remnants of fetal degeneration (which may then continue stationary

* On the other hand, the second case recorded by Beckmann (p. 239), in a woman aged 69, is undoubtedly an instance of renal cystoid in the sense adopted by me. If the woman had not died of pneumonia, complete cystoid degeneration might have been developed.

or may subsequently be further developed), or to seek after other explanations.*

Beckmann, with very little tendency to seek the primary changes in the pyramids, had already, as we have seen, hazarded conjectures respecting "interstitial diffuse nephritis in the cortical substance" as the predisposing cause of renal cysts. The cysts, occasionally occurring in Bright's disease, prove the possibility of such a process, which may also easily be theoretically conceived. But it is doubtful whether, where cyst-formation occurs as a fundamental morbid process (cystoid) such an interstitial nephritis occurs as cause. No special observations on this point are on record. If cystoid were capable of being thus developed, we should, in addition to the fetal form with uric acid infarction, and atresia of the papillæ, and that of the involution period, with calcareous infarction and closing of the pyramidal canals in the papillæ, be obliged to assume the existence of a third form, of which it should then be proved whether it can occur at every age. Indeed, the truth that the changes, which existed in my case are, as I think, to be regarded as typical of the cystoid occurring in advanced life, must be established by subsequent investigations. The case described by me *proves* only that atresia of the pyramidal canals and extensive calcareous infarction *may* be the cause of renal cystoid. Many observations and investigations are still necessary.

From the theory of renal cystoid just described, the signification which I attach to calcareous infarction follows spontaneously. As we have seen, nothing has as yet been fully established as to the influence of the infarction. We cannot easily imagine how it occurs if it be referred exclusively to chemical change in the urine. The simplest idea of crystallisation or precipitation in the tubuli uriniferi can scarcely be the true one, because we do not clearly see how accumulation and obstruction can thus take place. Indeed the tubuli uriniferi become steadily wider as they approach the renal papillæ, and yet it is precisely in the papillæ that we find the calcareous infarction. Even if we assume the solidification of the lime in the cortical, or narrower pyramidal tubuli, and a shifting towards the papillæ, the matter does not become plainer, for there is no reason why the calcareous granules should not in that case be washed away with the urine.†

The formation of the calcareous infarction would therefore appear rather to be consecutive to organic changes in the epithelial cells of the tubuli uriniferi, or of the interstitial connective tissue. If this takes place at an advanced time of life, we have in the chemical processes of the metamorphoses of matter, a predisposing cause of calcareous deposition in the newly-formed products. We see this most distinctly in the new formation of connective tissue in the walls of arteries, upon which calcareous infiltration usually follows. With such a process I should wish to compare the calcareous infarction of the renal papillæ.

Consequently neither is it the essential one of the changes in the pyramids, just as calcification of the spots formed in advanced life in the arterial walls is not necessary. The calcareous infarction in most cases only supervenes, and will then contribute its influence. Support for this view is to be found in the fact, that in the altered

renal papillæ the calcareous infarction occurs as well in the connective tissue between the tubuli. There is, however, very little interstitial connective tissue in the papillæ. But if the calcareous infarction is extremely developed, it is irregularly scattered throughout. It seems, nevertheless, that even in the commencement the increased and condensed connective tissue contains earthy granules, of which I think I have satisfied myself, especially by the clearing of the preparation through the action of dilute hydrochloric acid. The calcareous infarction would, therefore, not be the most important element in the formation of cystoid; cases may probably occur, in which only the interstitial changes in the connective tissue exist, and produce atresia of the renal tubuli. On the other hand, in the ordinary involution changes of the kidney, slight and very much scattered calcareous infarctions may occur without cysts. In the case investigated by me the calcareous infarction was so extensive, that scarcely any spots could be found, where only increase of connective tissue without calcification existed. Such spots were, however, present, and exhibited, especially on transverse sections, the openings of the narrow tubuli uriniferi obstructed, while of the wider tubuli many were still freely open.

The same considerations may probably apply in a greater or less degree to the fetal atresia of the renal papillæ. We do not find in Virchow any definite theory of the relation between the uric acid infarction and the fetal inflammation of the renal papillæ. In his essay on uric acid infarction (l.c. p. 843), he seems to attach the greatest importance to the filling up of the tubuli with uric acid: "Such a deposit is met with exceptionally also in the fœtus, and there gives rise to renal dropsy without obliteration of the ureters." On the other hand, in his essay on "Congenital Renal Dropsy," the uric acid infarction is taken less into account, but the fetal inflammation of the papillæ is mentioned (l.c. p. 872). Which of these processes is the primary? or does the renal cystoid arise at one time from uric acid infarction, at another from fetal inflammation and atresia of the renal papillæ?

I must, in conclusion, speak a few words respecting the rapidly sudden termination of the illness in the case described by me, while under other circumstances cystoid degeneration may be developed to an extraordinary degree, so that scarcely a trace of the renal tissue remains, and we must feel surprised that any urinary secretion took place. That in my case the cyst-formation in the kidneys must be looked upon as the sufficient cause of the symptoms and of the patient's death, and that, had the woman lived longer, a complete renal cystoid would have been developed, cannot reasonably be doubted. But what, then, gave rise to the rapid course of the disease and to death under the uræmic symptoms mentioned? Why are there in other cases such a chronic course and complete development of the cystoid? It is not possible to give a short satisfactory answer to these questions, although we may give ourselves some explanation of the facts, particularly basing it on the analogous phenomena in other morbid processes, precisely and chiefly in the kidney. In parenchymatous changes of the renal tissue, too, in Bright's disease, the process lasts at one time long, and a complete atrophy of one kidney is developed; in other instances the patients die suddenly or rapidly of uræmic intoxication. In tuberculosis of the kidneys, too, we observe something similar. The cause of this difference lies apparently in the various modes of extension of the organic process in different cases. We may imagine that, from step to step, as it were, the renal tissue becomes unfitted for its function, so that, to the last, parts may continue to act, while the greatest portion is already in the highest degree morbidly altered. On the contrary, in other cases the primary changes, whereon the subsequent degeneration depends, may spread over the whole or the greatest part of the renal tissue, so that even in the beginning the function suffers extremely. I shall not enter upon a consideration of the details in such processes, which are for the most part unknown, and consequently

* It scarcely need be said that we here refer always to cyst-formation as a fundamental morbid process, in which the morbid phenomena and the death are determined by the cyst-formation, and not to the cysts occurring accidentally in the course of other alterations of tissue (Bright's disease, &c.)

† Neither does Henle's discovery of the looped pyramidal tubuli quite clear up the matter, since, as has appeared subsequently from Ludwig's investigation, the looped tubuli are connected with the tubuli opening in the papillæ. It is, however, not to be denied, that we may expect accumulation of precipitated matters rather in the loops. Both the uric and the calcareous infarction seem to occur chiefly in the looped tubuli.

can be explained only by lengthened arguments. Perhaps, in the case I have described, some importance may be attached to the great extent of the calcareous infarction of the renal papillæ. Neither shall I enter into speculations as to the co-existence of cysts on the surface of the liver and of the ovaries with the cystic degeneration of the kidneys. In Virchow's latest book* we find observations on the occurrence of these cysts in the liver, which are undoubtedly produced by increase of connective tissue in the organ and constriction of distended biliferous ducts. The fact that these cysts in a cirrhotic liver, and the renal cysts, occurred in the same body, is, moreover, important enough, and quite accords with my theory that the renal cystoid in adults is dependent on an "abnormal" involution process in the kidney. It would seem that in the liver and in the kidney a "peculiar modification" existed of the process, which may otherwise lead to simple atrophy, but on this occasion gave rise to extensive cyst-formation.

d.—*Difference in the Origin of Cystoid Kidneys and of Hydronephrosis.*

Diagnostic Observations.

When we compare a typical case of hydronephrosis (distention of the pelvis and calices of the kidney) and one of cystoid degeneration of the renal tissue with each other, it appears as little possible to confound one with the other as it is to trace a connexion between the two processes. Yet earlier pathologists did not always draw the line of distinction strictly between them, and cases occur in which, at the first glance, the difference between the two processes is not so very evident.

With calculi developed in the renal tissue, after some parenchymatous morbid processes in the kidney (tuberculosis, some forms of Bright's degeneration, &c.), we occasionally find cysts in the cortical renal tissue and dilatation of the renal calices united; or only the last is met with, such that scarcely any remnant of the renal tissue is discoverable. The whole kidney is then changed into a cavity, which is filled with serous fluid, and is formed into as many divisions as there were Malpighian pyramids.

It is evident that in such cases the pathogenesis explains itself, and determines what affection exists. Renal cysts have always arisen in the tissues of the kidneys; and although, by their further development, the latter may be completely destroyed, so that the distinction between these cavities, filled with serous fluid, and dropsical distention of the renal calices, no longer appears so great, there nevertheless always exists a fundamental difference.

Therefore, too, this distention of the renal calices will be classed with hydronephrosis, although it is the peculiar character thereof that the distention of the renal pelvis is in such cases either wholly absent or that it exists only in a slight degree.

In the cases communicated by Virchow and others, of congenital cystoid degeneration of the kidneys, there was also often closing of the renal pelvis or of the ureter. Virchow correctly distinguished these cases in principle, from the cystoid degeneration by atresia of the renal papillæ, and with open renal pelvis and ureter. In fœtal degeneration, however, the one occurs combined with the other; yet, it is evident that, as there is both atresia of the papillæ and closing of the great efferent tube, only cystoid degeneration can be developed.

Our view of renal cystoid makes us cursorily devote a few words to the reasons why, in closing of the pyramidal tubuli cysts, in closing of the ureter hydronephrosis arises. In so doing we leave out of consideration dropsy of the renal calices from changes of the tissue of the kidneys, and keep in view only the mechanism of the origin of the two processes mentioned.

At the first glance it may appear that the closing of the ureter, and the accumulation of the urine therein and in the pelvis of the kidney, are as likely to lead to dilatation of the tubuli uriniferi in the renal tissue and to cyst-

formation, as closing of the pyramidal tubuli is. Yet we do not find the causes of hydronephrosis to produce renal cystoid, but we find, in great distention of the pelvis of the kidney, the gland, as it were, taken into the wall of the cavity filled with fluid, extended, flat, and atrophied. A little reflection will at once show the cause of this. But that the argument is not understood appears from those cases where, in the commencement of a process of hydronephrosis, such cysts are met with in the renal tissue. We find it mentioned and delineated in Rayer. "On observe bien rarement (in hydronephrosis, from obstruction of the ureter) de petits cystes urinaires et calculeux dans la substance corticale" (l. c. page 481, T. iii., represented in the Atlas, pl. xxv., fig. 7).

It is very probable that in every case of distention of the renal pelvis, dilatation of the tubuli uriniferi follows, and that cyst-formation would take place if a mechanical element were not at work to hinder it. While in atresia of the renal papillæ, the urine excreted higher up cannot flow away, against the distention of the convoluted tubes only the resistance of their walls is opposed, as well as that of the pressure which the tunica albuginea of the kidney exercises on the renal tissue increasing in extent. But these resistances are not strong enough to counteract the dilatation of the tubuli uriniferi, which, in connexion with the subsequent changes of tissue, gives rise to the cyst.

In the closing of the ureter and the dilatation of the pelvis of the kidney, we have, however, totally different mechanical relations. Here the renal tissue is itself compressed between the tunica albuginea (and the external surrounding parts) and another body which, always increasing in extent, distends the hilus renalis, and presses powerfully against the hollow surface of the kidney. Although the same cause which effects the distention of the renal pelvis must necessarily produce accumulation of urine in the tubuli uriniferi, the dilatation and cyst-formation of the latter cannot take place (or only exceptionally in some places), because the compression of the renal tissue in mass is stronger than the pressure which the urine accumulated in the renal tubuli exercises. Compression and atrophy of the kidney must inevitably be the result.

As the result of the two processes (cystoid degeneration and hydronephrosis), however, a large sac (uni or multilocular) finally arises, which may often be felt by external palpation of the abdomen.

An absolute diagnosis of the accidentally occurring renal cyst, or of an incipient period of the extensive cyst-formation, which leads to complete degeneration, is not possible during life. Another question is, whether the renal cystoid, when it is gradually developed, like what occurs in advanced life, and thereby attains the remarkable size which it acquires in those cases, cannot be recognized?

I believe that this will occasionally be possible, partly by the feel of the tumour, partly by the knowledge which we possess of the time at which, and the circumstances under which, the renal cystoid is usually developed. I have not, however, met with any example of a renal cystoid recognized during life. Only Rayer speaks of the possibility of a diagnosis: "If the kidneys had much increased in size, it would perhaps be possible to recognize this alteration during life." (l. c., t. iii., p. 512.)

A very instructive case of hydronephrosis, and one which particularly corroborates this opinion as to the possibility of diagnosing renal cystoid, was observed and investigated by my friend, Dr. Schmidt of Rotterdam. It is recorded in the *Nederlandsch tijdschrift van Geneeskunde*, 1861, p. 522. No absolute diagnosis was made in this case (in which a tense tumour was felt in the right lateral mesogastric region), but it was stated to be most probable that "large cysts or vesicular tumours were developed in the right kidney, as frequently occurs in advanced life." Again, after continued observation, just before the fatal termination of the disease, the supposition of the existence of "a cystoid tumour in the right kidney, pressing upon

* *Krankhafte Geschwülste*, u.s.w., D. I., pp. 256, et seq.

the cæcum and ascending colon" (page 524), seemed best to explain the symptoms.

Although on post-mortem examination this opinion proved not to be exactly correct, as hydronephrosis and dropsy of the renal calices existed in consequence of the obstruction of the ureter by a firmly impacted calculus, I believe that this case proves much for the possibility of the diagnosis of the true renal cystoid. In Dr. Schmidt's case there were so many particulars which rendered the diagnosis difficult, that we cannot draw any unfavourable conclusion from the assumption of the existence of cystoid instead of hydronephrosis by such a practised diagnoser. If a similar case occurred, and if, first, *both kidneys were affected*, whether equally or one more than the other, and if, secondly, not a smooth but a nodulated surface of the tumour could be felt, it is not likely that a mistake would be made, were the presence of cystoid degeneration of the kidneys assumed.

According to the cases hitherto published, cystoid degeneration, in fact, occurs always on both sides. This is, on the one hand, a difficulty in the diagnosis (as, of course, the possibility of unilateral development cannot *a priori* be denied), but it is, in virtue of the experience hitherto attained, in a still greater degree an assistance in distinguishing renal cystoid from hydronephrosis, which in its local phenomena and in its results *may* too closely resemble it. In general, however, it will not do so. An attentive study of the history of the case, and the circumstance that in hydronephrosis lateralis death ensues rather from the mechanical effects of the tumour, or from adhesion of the intestines to it, or in some cases from inflammation and suppuration, will often make its diagnosis from renal cystoid possible. At last, however, death occurs, either during the development of the degeneration (then as yet only to be suspected, not to be diagnosed) under stormy anæmic phenomena, generally in a few days; or if it be a typical case in the period of involution, with gradually diminishing urinary secretion and failure of strength, but without the symptoms dependent on the local influence of the tumour, which from the nature of the thing are to be expected rather in hydronephrosis.

Utrecht, September 23rd, 1864.

EXPLANATION OF THE PLATE.

Fig. 1.—A part of the one half of the kidney on the surface of section, in order to show the peculiar striped appearance of the pyramids, especially at the renal papillæ. Of the appearance of the cyst on the outer surface a gives an idea.

Fig. 2.—Longitudinal section of a renal papillæ. Calcareous infarction and displacement of the tubuli uriniferi by connective tissue. Calcareous granules irregularly scattered throughout, but particularly aggregated in the tubuli, or by their appearance and direction showing here and there still more distinctly the position of the former tubules. Magnified 60 diameters.

Fig. 3.—Transverse section of an affected renal papilla. A spot is chosen where, next to a closed spot infiltrated with cretaceous matter, some openings of straight pyramidal canals are to be seen. The narrow tubules (Henles) are all obstructed. Magnified 180 diameters.

DOUBLE UTERUS.—At a meeting of the Medical Society in Vienna, Dr. Späth related the following case which had recently come under his notice:—A girl aged 18, primipara, was admitted into hospital. On examination there was found to be a double os uteri, and the existence of a bilocular uterus was therefore suspected. After the first labour-pains had set in, the patient was seized with convulsions, which recurred, and ended fatally in spite of the hypodermic injection of acetate of morphia. During life, it was found that both orifices were dilated, and gave the sensation of an os uteri divided by a band: this was divided by scissors, and the child was discovered presenting transversely. After death, the uterus was found to consist of two cavities, of which the right was somewhat larger than the left.—*Wiener Medizin. Wochenschr.*

ABSTRACT OF METEOROLOGICAL AND MEDICAL OBSERVATIONS TAKEN AT THE MILITARY HOSPITAL, NICE,

FROM THE 10TH TO 20TH FEBRUARY, 1866.

By Dr. CABROL,
CHIEF PHYSICIAN TO THE HOSPITAL.

Translated by R. CROTHERS, M.D., Nice.

THE pressure of the atmosphere as indicated by the barometer has oscillated between 0.753 and 0.764, presenting between these extremes a difference more considerable than usual this winter. The weather has also been variable the last ten days. The mean temperature was 54 in the first part of the decade and only 50 in the latter, which is to be attributed to the influence of the prevailing winds, which have blown (sometimes violently) from N.E., N. and even N.W.

In our last bulletin we congratulated ourselves on the mildness and brightness of the atmosphere at the beginning of the month; such is no longer the case; during several days the sky has been often overcast; there have been very slight showers, inappreciable by the pluviometer (rain gauge), scarcely sufficient to lay the dust, which has been annoying, being blown about by the violence of the winds. The wind always falls towards evening, and the nights have been calm and fresh, some even a little cold, as the thermometer fell to 34°. The sea has been often rough.

We have remarked that the winds, which blow rather violently, begin at about the same period each year, and appear to correspond with the elevation of the mercury of the thermometer, which then attains the height of 104 or even higher, an increase of temperature which precedes the high winds by some days.

In presence even of such meteorological phenomena we have only to state the appearance of slight affections. The return and aggravation of rheumatic pains of all kinds constitute almost the only disease. *Apropos* of the constitution medical, we take this opportunity to reply to some observations suggested by our bulletins.

By the medical constitution of the time, we understand (*Tensemble*), the whole of the characters which meteorological changes impress upon the appearance or origin, the progress, duration, and termination of diseases.

Persuaded that in this study, physicians (principally those at places of winter resort) will find indications useful in the treatment of diseases, we shall publish with our notices of physical phenomena, the results which we experience of their influence upon the diseases of the period. It is this study which constitutes the principal importance of the meteorological and medical observations which we have established at Nice.

The dry winds which prevailed during the above period were trying to some cases of advanced consumption amongst the visitors, causing increased frequency and hardness of cough, with restless nights. These cases are now relieved by the advent of the spring rains, which have set in since the publication of the above bulletin.

CASE OF IDIOPATHIC INTERMITTENT EMPRASTHETONAS, CAUSED BY CANCER OF THE BRAIN.

By Dr. GEMMA.

Translated by T. M. MADDEN, M.D., M.B.I.A., &c., &c.

B. C., aged twenty-five, of robust constitution, although the daughter of pellagrous parents, had always enjoyed good health until July, 1862, when her menses ceased without apparent cause. Soon after this she was one day suddenly attacked by intense pain in the frontal region, screamed loudly, and then at once became lock-jawed, and at the same time her head was thrown violently for-

ward. She showed by her gestures that she understood what was said to her, although incapacitated from responding. The attack lasted for three hours, at the end of which time these symptoms disappeared completely, with the exception of some slight confusion of ideas, which was recovered from next morning.

After this date a similar seizure recurred every fifth or sixth day, her general health being apparently unaffected in the intervals. No cognizable exciting cause for the disease could be ascertained to exist.

She continued in the above-described condition for four months, during which blood-letting, purgatives, and iodide of potassium were tried in succession, but without benefit. At last, on the 12th of October, a final paroxysm occurred, intelligence was completely destroyed, though sensibility remained, and at the end of an hour the patient, after a violent spasm, sank down and died.

On a *post-mortem* examination the arachnoid membrane was found congested, the left hemisphere of the cerebrum was much softened, and in the corresponding hemisphere of the cerebellum there was also softening, though not to so great an extent. The *ramallissement* was more considerable in the interior than in the posterior portion of the left hemisphere. In the centre of this hemisphere a tumour of the size of a poulet's egg was found, formed by a gelatinous tissue containing a small nucleus of a fibro-cartilagenous structure. The right hemispheres of the brain and cerebellum, the corpus callosum, and the spinal cord, presented no pathological change. The intestines were slightly congested; the other viscera were healthy.—*Gazette Medicale.*

PROGRESSIVE LOCOMOTOR ATAXY, FOLLOWING ANGINA DIPHThERITICA.

A MAN, aged 31, who had previously had good health, came under treatment for a deep diphtheritic ulcer of the right tonsil, which caused pain in swallowing, troublesome accumulation of mucus in the throat, and was accompanied with cardialgia, and suddenly occurring paroxysms of suffocating, coming on especially at night. Three weeks after the diphtheritic affection commenced he had a fall from giddiness, and during the next eight days he became very feeble, and impairment of memory, heaviness of the legs, and a dragging, staggering gait came on. He walked better quickly than slowly, and worst in the dusk, as he required to see his feet in order to direct the movements of them. Then sight began to get dim, and after fourteen days everything appeared as if shrouded in a thick mist; but there was neither strabismus nor double vision, nor any drooping of the upper eyelids; the pupils were normal, and the iris freely mobile. Deglutition ceased to be painful, but became difficult, food returning by the nose. The soft palate hung loose, and flapped on deep inspiration. The ulcer in the still swollen tonsil was deep, but clean. Some days later taste was lost for all but sweet things, a solution of quinine not tasting at all bitter. Peculiar pricking and shooting pains affected the middle of the hard palate and the right corner of the mouth. The nape of the neck was sensitive, and the head could not be held up straight, the muscles of the nape having lost power. The giddiness increased, and he became very drowsy. Later the pricking pains affected the ulnar border of the right hand, and the tips of the fourth and fifth fingers, and the sensibility of those parts was diminished. The voice became highly nasal. He could no longer see his feet, and his gait became extremely uncertain and staggering. There was obstinate constipation, and though laxatives were taken daily the bowels were relieved only once in four or even six days.

On the 22nd of September sight returned quite suddenly, after having been lost for a month. Some days later memory was restored, and the giddiness, the drowsiness, and the pricking pains in the gums and corner of the mouth all ceased. But as the cerebral symptoms disappeared, affection of the spinal cord rapidly increased. Pain fixed itself

in the upper vertebra. The sensations of fornication, cold, and deadness in the hands and feet changed in four-cen days into complete anæsthesia. Everything felt to the patient as if his hands were covered with woollen gloves. He could not take up small objects, nor hold fast larger things when given him; he could neither write nor convey food to his mouth; but he could distinguish between heat and cold, and the latter seemed to rather increase the sensibility. In the feet and legs up to the knees he felt an icy coldness, and he could only just feel the ground under his feet; he could neither stand nor walk alone, for he felt as if rocking constantly to and fro. Peculiar convulsive movements of fingers and toes now came on, some being extended, others flexed or abducted, the movements being altogether beyond his control. He could still taste sweet things, but nothing else. To this was added complete insensibility inside the mouth; difficulty of deglutition continued. If in the dusk he folded his hands together, he could never separate them till light was brought so that he could see the positions of the fingers. In the beginning of October the delusive rocking motion ceased, and the patient could no longer, when he put down his feet, feel the ground; he was obliged always to sit or lie; he could not rise up without aid, and when lifted up, his legs would not support him; but while lying he could stretch out the legs with tolerable force; he could give a squeeze of the hand, and could swing the arms backwards and forwards, but was not able to lift them up. At this time the dysphagia suddenly quite disappeared, so that the patient could again satisfy his imperious appetite. The impulse to eat came on suddenly, and if he could not quickly satisfy it he grew faint. The swelling and ulceration in the tonsil had disappeared, but the voice remained nasal. In the middle of October the icy coldness of the legs ceased, giving place to an agreeable sensation of warmth. In the latter half of the month, however, the paralysis of the lower half of the body reached its highest degree, and the pain in the back was felt lower down towards the loins. For some days the patient could not feel that he sat, and had no sensation in the genitals. The government of the lower extremities was entirely lost, and when the patient was held up on both sides he dragged his legs after him as if quite inanimate; yet he could, when lying on a sofa with his legs up, stretch them forcibly out. He sat always bowed extremely forwards, and could only raise himself straight for a moment. (Edema of the feet came on; the urine was clear and frothy, but contained neither sugar nor albumen. In the middle of November the above-described symptoms began to gradually disappear, so that in December all the functions were again normal; only some difficulty in writing remained. By the end of the year, however, this had ceased; he was perfectly well, and had gained flesh.

The treatment "did not differ from that usually adopted in such cases." It may be mentioned, however, that the patient through a long period took strychnine—1-20th of a grain, cautiously increased to 1-12th, morning and evening, every twelve days discontinuing its use for four days.—*Brit. and For. Medico-Chirurgical Review.*

ERRATIC COURSE OF A BULLET—At a meeting of the New York Pathological Society, Dr. Sands showed a bullet, which had been removed from a soldier who had been wounded in June, 1862, in the region of the upper right eyelid. The wound was perfectly healed, when some time ago he presented himself at the Eye Dispensary. He had been examined by surgeons in the army, but no bullet had been detected. On close examination, a swelling was discovered behind the ear, near the insertion of the sterno-cleidomastoideus muscle, which, presenting the features of a hard foreign substance, was cut down upon, and proved to be an ordinary conical rifle projectile. It was imbedded below the above named muscle, in the fibres of the splenius capitis. The case showed how extensively these projectiles may travel through, or in the neighbourhood of, important parts, without inflicting serious injury, or giving rise to much trouble.—*Phil. Med. Rep.*

Proceedings of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEB. 27TH, 1866.

Dr. ALDERSON, F.R.S., President.

ON GRANULAR DEGENERATION OF THE VOLUNTARY MUSCLES.

By E. MERYON, M.D., F.R.C.P.

SINCE 1851, when Dr. Meryon communicated to the above-named Society an account of this disease, the details of which were published in its "Transactions" in 1852, four more cases have fallen under his observation. In one, which terminated fatally in 1859, the post-mortem examination was carefully conducted by Mr. Savory, who, during a searching microscopical investigation, failed to detect a vestige of disease in any part of the nervous system. The disease appears to consist in a gradual but progressive breaking up of the amorphous membrane which envelops the primitive muscular fibres, and of a dispersion of the contained granular matter. After these preliminary observations, Dr. Meryon proceeded to describe the case of a gentleman, aged twenty-two, who was present at the meeting, so that the Fellows had an opportunity of examining his present condition. At the age of five years he began to show symptoms of weakness in the loins by a waddling gait; and, in the course of two or three years, he had difficulty in bending the thighs on the body, as in the act of getting up stairs; next he gradually lost the power of bending the legs on the thighs; and eventually the voluntary motions of the feet and toes were lost also. The morbid action then began to manifest itself in the upper extremities, and the patient has now no longer the power of raising his arms to his head; but he can bend the forearms on the arms, and he still retains a firm grasp with the hands. The tendency of the disease, however, is to extend itself from the proximal to the distal portions of the extremities, and then to attack the muscles of respiration; but in no case are the involuntary muscles or muscles of organic life affected. The history of one case is the history of all; and on the uniformity of the symptoms and the order of their appearance, &c., Dr. Meryon has attempted to distinguish this form of paralysis from all others which are dependent on lesions of the peripheral nerves or nervous centres—1st, by the centrifugal course of the disease, irrespective of the course and distribution of nerves; 2nd, by the entire absence of any symptoms of nervous disturbance during life; and 3rd, by the absence of any trace of lesion in any part of the nervous system after death—at least so far as the most careful investigations have extended up to the present time. There is another difference observed in the muscles thus affected, as compared with paralysed muscles dependent on nervous lesion: it is in the disruption of the sarcolemma and the segregation of the granules which constitute the sarcous matter in the former case; whereas, in the latter, the primitive fibres gradually waste, the transverse striæ gradually disappear, and oil-globules by degrees fill the interspaces of the fibres, and occupy the space which the healthy muscular tissue formerly occupied. Dr. Meryon's patient affirms that both he and his sister, who is also a subject of the disease, have retained the condition in which they were when they began to take arsenic. The gentleman has been under the influence of that medicine a little more than a year. In conclusion, Dr. Meryon adverted to the question of priority of description of this peculiar form of disease. He quoted passages from several of the French medical periodicals in relation to this matter. It is unnecessary to report these, though the following fact may be mentioned—that at the Academy

of Medicine M. Cruveilhier referred to Dr. Meryon's plates in illustration of his (M. Cruveilhier's) own diseased muscles, and called the attention of the Academy to a form of paralysis "non encore décrite." Dr. Meryon's paper had been published in the *Lancet* more than a year before, and shortly afterwards appeared also in the Society's Transactions.

Mr. SKEY said that during a period of some fifteen months, in which he had the charge of the young gentleman of fifteen years of age alluded to by the author, he was informed of an example of a similar disease in one family only, residing in a remote part of Dorsetshire; and with regard to treatment, nothing satisfactory had yet been accomplished. The case related in the paper was interesting from the circumstance that the manifestation of a morbid condition of the muscular system was not developed till a late period of childhood, or rather perhaps an early period of boyhood—namely, eight years of age. In all the cases with which he was acquainted the change from health to disease commenced in infancy; for while these children were still in their nurses' arms they showed a want of activity and elasticity of movement peculiar to the disease. Again, he observed another peculiarity in the fact that in the cases quoted by the author the change of structure was not confined to one sex; whereas in the two families under his cognizance the females were entirely exempt, and it was the more remarkable because in the family of — the daughters were noticeable for their healthy and handsome appearance. Nor was it possible to trace the disease from either parent to their male offspring. In the case reported on by the author the morbid changes were confined to the family of the father by his second marriage, thus exempting him from suspicion of personal taint. Supposing the disease to be hereditary, it seemed reasonable to infer that it was obtained through the maternal channel. The treatment adopted consisted in the resort to tonic agents of various kinds—iron, bark, wine, mineral acids, and animal food; but most especially, were all the muscles maintained in active exercise at least twice daily, and persisted in up to the point of fatigue: all, however, as the post-mortem appearances showed, without the least benefit. There was one striking feature in this case which he was inclined to consider common to them all—namely, that the morbid changes in the sarcous elements were confined to the muscles of animal life. In the muscular tissue of organic life (the unstriped fibre) no change had occurred; and this he was prepared to expect from the perfectly healthy condition of all the internal functions during life. It could not, then, be asserted that all the muscular tissues are involved, but only those of animal and external life. This fact throws some doubt on the supposed source of the diseased changes in the muscular tissue itself; because if one system be primarily involved, why not both? The sarcous elements are the same, though differently arranged. Why should the myogenic property be arrested in one case and not in the other? If dependent on a morbid state of the nervous centres we must look to the spinal cord, and exclude the ganglionic system, which for the most part supplies the muscular fibre of organic life.

Mr. SOLLY said that though he did not deny the probability of muscular atrophy without disease of the nervous system, he was sure that this view of the pathology of the cases described by Dr. Meryon could not be admitted unless there were more complete proof of the spinal cord being perfectly healthy. He felt confident that, in order to detect disease in the spinal cord, it was necessary to examine thin slices of it under the microscope, prepared according to the process enunciated by Mr. Lockhart Clarke; and that until that had been done, we remained in ignorance of the pathology of the disease.

Mr. G. L. COOPER said it had fallen to his lot to see two such cases, and in both instances the symptoms were slow, insidious, free from pain, and ending in a complete degeneration and atrophy of the muscles. He believed that we may assign this disease to a softening of the brain,

accompanied by an accumulation of fluid in the coverings of the spinal cord pressing on the nervous centre. The first case was that of a gentleman, about forty-five years of age, who complained of a pain in his right shoulder, which was soon accompanied by an inability to raise the joint, with an apparent wasting of the deltoid. The muscles of the arm and forearm after a time became flabby and soft, and soon showed a degeneration and atrophied condition of their structure. The left arm has subsequently wasted, and he (Mr. Cooper) suspected would follow the course of the right. The second case was that of a coachman, aged forty-one. He had drunk freely in his early days, and had been exposed very much to the severity of the weather day and night. He suffered from a bad cough with profuse expectoration for many years, but was able to continue his employment until about three years ago, when he noticed a weakness in the thumb of the right hand, which disabled him from holding the whip. The hand soon wasted, and was followed by the forearm and arm in the same condition, with a total loss of power over their action. The left hand and arm were attacked in a similar manner about a year ago, and continued the same course as the right, ending in complete degeneration and paralysis of the extremity, but with more rapidity in its destructiveness. About six months ago his feet, legs, and thighs were similarly diseased, and followed precisely in the same course, ending in complete atrophy or degeneration, with total paralysis. This wasting was not observable in the muscles of the trunk, and the internal organs exercised their functions with a due regularity.

Mr. LOCKHART CLARKE said that the interesting case which Dr. Meryon had exhibited was considered by him to be one in which there was no lesion of the nervous centres. This opinion was grounded on the absence of pain in the wasting muscles. Now, the absence of pain in wasting muscles was no more a proof that their atrophy is independent of lesions of the nervous centres than absence of pain was a proof of the same independence in cases of motor paralysis. And as we had muscular paralysis without pain, but dependent on lesions of the nervous system, so he believed we might have muscular atrophy without pain, but dependent on the same cause. But whatever *a priori* opinions might be formed on the subject, the question could be decided only by the evidence of post-mortem examination. A few months back a very decisive case came under his notice; or, rather, he received from Mr. Paget the pons Varolii, medulla oblongata, and part of the spinal cord of a child who had died with muscular atrophy of the upper extremities and of other parts, but who had never, he (Mr. L. Clarke) believed, experienced any pain whatever. In the cervical enlargement a small area was discovered, in which the nerve-tissue of the central grey substance had undergone evident disintegration. The pons was healthy, as was every part of the medulla oblongata, except one, where some granular exudation was found extending through the spinal accessory nucleus from behind, and reaching forward into the nucleus of the hypoglossal nerve. At the same level the lateral parts of the medulla oblongata had undergone a certain amount of disintegration. As Mr. L. Clarke had not received any detailed history of the case, he wrote to ascertain whether the tongue was not in some way affected, and received an answer informing him that the tongue was the part in which the atrophy had commenced. Here, then, was satisfactory evidence of lesions of nerve-centres in a case of muscular atrophy in which there was no pain. This was the more important because pain was not experienced in more than about one-third of the cases of this malady. But when it did occur it was often very significant. Sometimes it took the course of particular nerves, either before or during the wasting of the muscles. Again, the nervous character of muscular atrophy was occasionally indicated by its beginning with an attack of temporary paralysis. Romberg had related a case which began with hemiplegia of the left side. The leg completely recovered, but the arm re-

mained weak, and its weakness corresponded with the wasting of its muscles. No pain was experienced.

Mr. HOLMES COOTE, in remarking on the interesting nature of the cases now before the Society, said that they were not so uncommon as some of the members supposed, but were "grouped together" in certain hospitals or under the care of special practitioners. He had seen, both in the adult and the infant, many cases of such progressive muscular paralysis—a disease which, in course of time, rendered even the bones light and easily broken. In the infant the functions of the sensorium were sometimes disturbed; sometimes not. So also in the adult. And no one had done better service in this department of pathology than Mr. Lockhart Clarke, who had succeeded in demonstrating morbid changes in the grey matter of the nervous centres. His investigations had paved the way to a better classification of these cases, by assigning to them in their varieties one common primary seat—namely, the grey matter of the nervous centres, from whatever cause such disease might arise.

Dr. FULLER said that it had fallen to his lot within the last few years to meet with seven well-marked examples of the disease, which, in their progress and in the mode of evolution of their symptoms, resembled precisely the cases related by Dr. Meryon. The cerebral functions remained unimpaired to the last, and the paralysis, which commenced very gradually, did not follow the course of particular nerves, but fixed upon particular bunches of muscles, first in one part of the body, and then in another, quite irrespectively of their nervous connexions. In some of the cases, pain in the limbs, and fibrillary twitching of the affected muscles were prominent symptoms; in others, pain was absent, but fibrillary twitching was well-marked; and, in two of them, there was no pain, and only the faintest twitching. In one respect Dr. Fuller's cases differed from those detailed by the author of the paper—they all occurred in adults, and in most of them the symptoms appeared to have originated in nervous exhaustion. In one instance, and in one only, the muscles of organic life appeared to be affected. In that case, which Dr. Fuller saw in consultation with Dr. C. J. B. Williams, the heart, about two months before the patient's death, became extremely feeble in its action, and the pulse fell to 26 in the minute. Dr. Fuller agreed entirely with Dr. Meryon in regarding this disease as quite distinct from ordinary paralysis; and he regarded it also as distinct from the creeping paralysis of the insane, which he believed to constitute the bulk of the cases referred to by Mr. Holmes Coote. As some confusion exists on the subject, Dr. Fuller thought it very desirable that a special title should be assigned to the disease, for at present the nomenclature is quite unsettled.

Dr. BARCLAY said that previous speakers seemed to him to have lost sight of the distinction which Dr. Meryon had sought to make between muscular degeneration as a cause of paralysis and those other forms which depend on disease of the nervous system. He (Dr. Barclay) believed that several different forms of paralysis had been referred to, and that when the correctness of some of the author's observations was impugned it was because other forms of paralysis presented symptoms different from those traceable in muscular palsy. The presence or absence of the symptoms referred to was the test by which the true character of the affection became known. This was particularly true of the so-called centrifugal direction in which the disease proceeded, in opposition to the ordinary course of gradually extending paralysis dependent on progressive disease of the nervous system.

Mr. LOCKHART CLARKE, in reply to Dr. Barclay, said that he had been asked whether the morbid changes in the nervous centres might not be the consequences of the muscular wasting. He was sure that the changes he had observed were not so; for they were not simple atrophy of the nerve-tissues, but disintegrations, arising either from softening or from morbid exudations. Moreover, he had lately examined the spinal cord (given him by Mr. Dickinson of St. George's Hospital) of an old pensioner

who had lost one of his legs a great many years ago; but he was scarcely able to perceive any difference between the two sides, and there was certainly nothing at all resembling the disintegrations that he had found in cases of muscular atrophy. For an account of these cases, which he had published, he would refer to recent volumes of the *British and Foreign Medico-Chirurgical Review*, and of Beale's *Archives of Medicine*, particularly to No. 13, vol. iv., which contains one of the most important and interesting cases of any disease on record. He did not, however, wish to be understood to mean that there was no such thing as muscular atrophy without lesion of the nervous system. Such a disease might exist, but the question could be determined only by a sufficient number of post-mortem examinations.

Mr. SKEY fully endorsed the truth of the observations of Dr. Barclay. They were discussing various forms of paralysis. He spoke only on that form described by the author of the paper, which is special, if not specific, and which consists microscopically of a deposit of oil or fat globules in the place of muscular tissue. He still believed the disease a very rare one.

Mr. SOLLY said he thought that Mr. Cooper's case was analogous to the scrivener's palsy, where a nervous centre was exhausted by overwork, and that it might be entitled the driver's palsy, adding another to the list, such as the musician's palsy (of which he had lately had a case under his care), the milker's, the shoemaker's, the nailer's, &c.; but there was no analogy between these cases and those of Dr. Meryon.

Dr. BARKER referred to a case of muscular atrophy which had been under his care in St. Thomas's Hospital. The patient was a gardener not over 40 years of age. The first symptoms of the disease were a tripping in his walk, and an inability to prune trees. These were followed by general loss of power. When he first came into hospital he was plump in appearance, but the muscles of the arms, legs, and thighs were wasted. With the exception of complete loss of muscular power the man was in every respect well.

Mr. HOLMES COOTE assured the last speakers that he had had very many opportunities of seeing such cases, not only in Bethlehem Hospital, but also at the Orthopædic and St. Bartholomew's; and that he was not at all likely to fall into the error assigned to him.

Dr. WEBSTER said, in reference to the author's statement regarding a recent speaker at the Paris Academy of Medicine, who had claimed the merit of being the first to notice the malady now under discussion, it should be remembered that French medical men rarely read English periodicals and seldom speak the language; hence no one ought to feel surprised if professional questions occupying attention in England do not always become immediately known beyond the Channel. In proof of this, he would mention that at the library of the learned body just named no English medical journal is accessible for perusal. At least, this was the case not long ago, when he visited the library of the Imperial Academy, where the only English periodical publication shown him by the courteous official of whom he made inquiry was the Registrar-General's Report of Marriages, Births, and Deaths, sent by the British Government. In fact, the tables of that institution are scantily supplied with foreign medical literature, and very unlike not only this Society, which receives numerous journals of various countries, but likewise dissimilar to several continental capitals, such as Stockholm, Lisbon, and others, which he might specify from his own personal observation. Therefore Dr. Meryon need not deem it strange whenever any French observer thinks himself an original discoverer, seeing the circumstances above related may perhaps furnish a satisfactory explanation of the assumption narrated.

The College of Physicians have approved of the Lord Provost's proposed plans for the sanitary improvements of Edinburgh.

Reviews.

ON FLOODING AFTER DELIVERY AND ITS SCIENTIFIC TREATMENT; with a Special Chapter on the Preventive Treatment. By LUMLEY EARLE, M.D., Obstetric Surgeon to the Queen's Hospital, Birmingham; Honorary Medical Officer to the Hospital for Sick Children, Birmingham, &c. Pp. 244. London: Hardwicke. 1865.

In this treatise Dr. Earle has brought together a great amount of useful and practical information upon a very common and very serious complication of the puerperal state, and one in which prompt and decisive conduct on the part of the obstetric practitioner may often save the patient from imminent death. Dr. Earle divides his book into eight chapters, the first being devoted to some preliminary observations; the second, to the signs and symptoms of post-partum hæmorrhage; the third, to the preventive treatment; the fourth, to the remedies which ought to be used to arrest the hæmorrhage; the fifth, to the causes of hæmorrhage occurring before the delivery of the placenta; the sixth, to the causes occurring after the expulsion of the placenta; the seventh, to the rare causes of flooding after delivery; and the eighth, to the after-treatment. In the chapter on preventive treatment, Dr. Earle strongly advocates the plan of applying the hand to the breast and using pressure, in preference to the application of the child to the nipple, and he also recommends the use of the binder as a most important precaution. In describing the various modes of treatment adopted during the period of the greatest peril, Dr. Earle lays especial stress upon the necessity of administering brandy, a supply of which, he justly observes, ought to be in readiness in all cases of difficult or dangerous labour, and which, he thinks, not only rallies the patient in cases of hæmorrhage, but also assists in arresting the bleeding, by inducing contraction of the uterus. In two or three lingering cases of labour, he observes, he has brought about a speedy termination of the case by giving a glass of hot brandy and water. Among some of the common, though often unsuspected, causes of hæmorrhage after delivery, Dr. Earle mentions distention of the bladder, and he states that he has met with some cases of flooding which were distinctly caused and kept up by the injurious influence of a distended bladder upon the recently unburdened uterus. In cases where the hæmorrhage is caused by a retained placenta, and the discharge has occurred rapidly and to an alarming extent, the hand should be at once introduced and the placenta removed; but when the discharge is more moderate a longer time may be allowed to intervene, and other remedies may be tried first, as cold and ergot; and in cases where there is no great loss of blood, half an hour may be allowed to elapse.

The foregoing brief abstract will show that Dr. Earle's treatise is thoroughly practical throughout, and we may add that most of his observations are founded upon extensive experience gained in actual practice. The book will be found very useful to the profession, many of the members of which are frequently called upon to treat the urgent symptoms described by Dr. Earle, and the readers will do well to store up in their minds the precepts he gives for their guidance in case of emergency.

THE HEALTH RESORTS OF THE SOUTH OF FRANCE. By EDWIN LEE, M.D. Second Edition, with alterations and additions. Pp. 213. London: Adams. 1865.

NICE AND ITS CLIMATE. Second Edition. By EDWIN LEE, M.D. Pp. 179. London: Adams. 1865.

SAN REMO AS A WINTER RESIDENCE. By AN INVALID. 1862-65. Pp. 128. London: Churchill. 1865.

Dr. EDWIN LEE's books on the Health Resorts of this country and of many parts of the Continent, are so well known, that

little more is necessary on our part than to announce the Second Edition respectively of his little book on the South of France and of its companion specially devoted to Nice and its Climate. Those who are seeking in those regions for the means of renovating their health will find Dr. Lee's pages a trustworthy guide, and instead of being confronted with technicalities in the perusal, will find a large amount of general and amusing information.

The little book on San Remo is written by Mr. Aspinall, who has himself derived signal benefit from a residence in that town, and he communicates the results of his own experience in a neat little volume, illustrated by several pretty views of the surrounding country. To those who may be unacquainted with the locality of San Remo, it may be stated that it is situated on the Italian shore of the Mediterranean, about thirty miles distant from Nice, and about fifteen from Mentone; and Mr. Aspinall states that it combines the advantages of both those towns as a health resort.

AN INTRODUCTION TO THE STUDY OF MEDICINE; to which is appended a Report of the Homœopathic Treatment of Acute Diseases in Dr. FLEISCHMANN'S Hospital, Vienna, during the Months of May, June, and July, 1846. By GEORGE WILLIAM BALFOUR, M.D. Pp. 307. Edinburgh: A. and C. BLACK. 1865.

THE author, in the preface to this little work, very justly observes that it is not intended to be exhaustive, but merely suggestive, for nothing else can be expected in a treatise on so wide a theme as the study of medicine, comprised in little more than three hundred pages. The subject-matter is divided into seven chapters, exclusive of the Appendix: the first chapter being introductory, the second being on medicine as an art, the third on life and death, the fourth on health and disease, the fifth on inflammation, the sixth on fever, and the seventh on chronic disease.

Dr. Balfour belongs to what is called the school of Young Physic, and he vigorously denounces the errors and mistakes of those who were or are attached to the old. He is in fact a disciple of the doctrines set forth by the late Sir John Forbes, and which procured so much approbation from some quarters and elicited so much opposition from others. We hardly know indeed whether it is more correct to say that Dr. Balfour is a disciple of Sir John Forbes, or that Sir John Forbes was a disciple of Dr. Balfour; for the Report on the Homœopathic Hospital at Vienna, printed as an appendix in the volume before us, was originally published in the pages of the *British and Foreign Medico-Chirurgical Review* while it was under Sir John's editorship; and the facts revealed in the Report appear to have made a great impression upon his mind, and to have contributed very materially to the formation of those opinions as to the relative part played by Nature and Art in the treatment of diseases which Sir John Forbes promulgated in the latter years of his life. Indeed the facts recorded by Dr. Balfour as the result of his sojourn in the hospitals at Vienna, both homœopathic and (the so-called) allopathic, are startling enough, and are quite sufficient to make the most devoted adherent of the old school of physic pause in his career and carefully review the grounds of his practice. Dr. Balfour was a pupil of the late distinguished physician, Dr. Alison, of Edinburgh, who, as is well known, advocated the utility, and indeed necessity of general bloodletting in the treatment of pneumonia; and we can imagine the surprise of the pupil who had been indoctrinated with such principles in 1844, and who in 1845 witnessed in the hospitals of the Austrian capital a practical refutation of their truth. In that city he attended the practice of Dr. Fleischmann, who presides over the large homœopathic hospital; and he also saw under the care of Dr. Skoda a great number of patients whose diseases were left to the unaided powers of nature.

While the former believed that he was curing diseases by the administration of infinitesimal globules, the latter "having reasoned himself into a thorough scepticism as to the utility of all medication, was giving all his patients an equal chance of attaining either of the only two possible methods of exit from their maladies—death or recovery—by withholding from them all such active medication as might influence the result."

We presume that this was only a temporary experiment on Skoda's part, because Dr. Balfour tells us in another portion of his book that Skoda treated his ague patients with quinine, and a comparison is drawn between the results of that treatment and the globulistic plan followed by Fleischmann. Dr. Balfour, it should be mentioned, is no homœopathist, and he attributes the cures which undoubtedly take place under that system to their true cause—namely, the abandonment of the disease to nature, and the withdrawal of all agencies which can interfere with her operations. But he is not so explicit in telling us whether Skoda remained convinced of the uselessness of all medication in all diseases, or only in acute diseases; but, for the reasons above stated, we conclude that Skoda admits that medicine may occasionally do good, as for instance in cutting short the duration of an intermittent fever.

As is usual with many of the followers of the School of Young Physic, Dr. Balfour ridicules the idea of any change having taken place in the type of disease, and he summarily disposes of that theory by alleging that Dr. Alison, Dr. Christison, Dr. Stokes, Dr. Watson, and many others who have entertained it, were all mistaken. They were quite honest in their belief, but they were misled by the influence of prevailing doctrines; and it is they who have changed their opinions and not disease which has changed its features. Bleeding and calomel were quite as unnecessary in the times of Armstrong, Cullen, Clutterbuck, Southwood Smith, and Marshall Hall, as they are now; and much mischief was done to the patients, who, although some may have survived the treatment, were really injured rather than benefited. Such is Dr. Balfour's reasoning, and he handles his arguments with great skill and considerable research.

Our space does not permit us to enter more fully into Dr. Balfour's work, which is, indeed, very suggestive, and is evidently the production of a thoughtful mind. Without endorsing all the conclusions he draws, we admit that his facts are most instructive; and we commend his pages to the careful study of the profession.

PAROCHIAL BOARDS AND MEDICAL OFFICERS.—At a recent meeting of the Committee of Works of St. George's Hanover-square, a member, Dr. Appleton, made some strong observations about the conduct of Dr. Aldis, a medical officer of health, in writing to *The Times* a letter recommending the abolition of dustbins and the substitution of wooden boxes for the reception of ashes, to be taken away by the dustcart twice a week. In reply to the attack made upon him Dr. Aldis wrote a letter to the Board stating that he had made a similar suggestion to the Sanitary Committee of St. George's in 1858. At a subsequent meeting Dr. Appleton renewed his complaints of Dr. Aldis's conduct in writing to *The Times* instead of communicating with the parochial committee, and expressed his surprise that if the suggestion made in 1858 was regarded as important it should have been allowed to rest until now. It was most indecent that officers appointed by vestries should attack them in the manner which was now becoming so common, as in the cases of Dr. Hillier in St. Pancras and Mr. Rendle in Southwark. Dr. Aldis repudiated any intention to cast discredit upon the Board, and said his only object in writing to *The Times* was the public good. Subsequently a motion was proposed that Dr. Aldis's proposition was impracticable, but after some discussion the motion was not pressed, and the subject was allowed to drop.

THE POOR-LAW BOARD AND THE MEDICAL PROFESSION IN ENGLAND.

THE Meeting of Noblemen, Members of Parliament, Members of the Medical and Clerical Professions, and of the general Public, which was lately held in Willis's Rooms, will do much towards bringing about a better system of attendance on the Sick Poor in Workhouses than that which at present exists. We are rejoiced to find Peers and Bishops uniting with persons of meaner estate in demanding justice for the sick pauper, and we hope that in their places in Parliament our Senators will always pursue the same benevolent course. The question of the nature and amount of Medical services rendered to the sick in Workhouses was necessarily introduced into the addresses made by several of the speakers, who, however, were but little informed as to the real relations existing between the Medical Officers and the Guardians, or as to the obstacles placed by the latter against the former in the discharge of their duties.

"With regard to the parish doctors," said the Chairman, the Earl of CARNARVON, "they no doubt were anxious to do all in their power; but they were only flesh and blood, and could not accomplish impossibilities. The doctor, in fact, ran through the wards as fast as he could, and his whole life was spent in a sort of confusion in endeavouring to keep things straight as between himself, the patients, and the board of guardians." The Chairman might have gone on to state that by the present system of electing the Medical Officers, and by the tyrannical conduct pursued towards them by the Guardians and encouraged by the Poor-law Board, the Medical Officers are deprived of all power of independent action; that they dare not, under pain of dismissal, remonstrate against any abuse, however flagrant; and that in matters strictly falling within their own department they are liable to be overruled by the other functionaries in the Workhouse, such as the master or the matron, or even the pauper nurses. The reports of the Medical Officers must be drawn up in accordance with the views of the Guardians, if any peace is to be secured; and can it be at all a matter of wonder that honourable men resign their appointments, or are dismissed, while those who remain at their posts continue to perform their duties in a perfunctory manner, knowing quite well that any attempt on their parts to ameliorate the condition of the sick poor would draw down upon themselves the displeasure of their taskmasters?

The position of Medical Officer in a metropolitan Workhouse is of the most anomalous character; and although he is supposed theoretically to be answerable for the care of the sick poor, it is impossible that he can

perform the duties imposed upon him while the present system continues to exist. We state only the bare truth when we assert that the Medical Officer of a Workhouse is looked upon only as a subordinate by the Guardians; and while the latter would never dream of contradicting their legal adviser on a point of law, they make no scruple of rejecting any proposition made by the Medical Officer, however much it may be sustained by the dictates of science or experience. In fact, as long as the "Doctor" goes through the wards and supplies sufficient "stuff," the Guardians are quite satisfied; but if he ventures to represent the existence of conditions unfavourable to health, or to suggest improvements in drainage, lighting, ventilation, or nursing, he is considered to be overstepping his province and to be guilty of an act of the greatest presumption.

Now such a position as this is held, so far as we are aware, by no other Medical Officer in charge of large bodies of persons nominally intrusted to his care. In Lunatic Asylums the Medical Officers have the supreme control over the management of the patients. Even in Prisons the sick prisoners are entirely under the direction of the Medical Officer; and in the Army and Navy these officers have always possessed the control of their own department. It may be said, and indeed it has been said, that the class of "Parish Doctors," as they are called, is of an inferior grade, compared with the other Medical functionaries to whom we have just alluded; but, in the first place, we do not admit that any such inferiority exists; and, in the second place, we assert that if the "Parish Doctors" rank too low in public estimation, it is entirely the fault of the operation of the present Poor Laws. In fact, on the principle of giving a dog a bad name and then kicking him, or hitting a man because he has no friends, the present Poor-law administration has degraded the Medical Officer, and then it abuses him because he has allowed himself to be degraded. We do not claim for the Workhouse Medical Officer any exemption from the faults and the failings of humanity, and we do not deny that there may be cases where the duties of the office may be unsatisfactorily performed; but in the first place, the Poor-law Executive is armed with the most ample powers to punish any dereliction in this respect, and in the second place we cannot criticise very closely the performance of duties so badly paid as are those of the average "parish doctor." He, like other human beings, must live; and as it is impossible he can live on the pittance doled out to him, he must either starve or eke out his income from some more profitable source than his parish duties.

While feeling every good wish towards the benevolent objects contemplated by the meeting at Willis's Rooms, we cannot help thinking that the machinery at present in operation is amply sufficient to remedy existing abuses if the administrators of the Poor-laws could be urged to perform their duties. The care of the Sick Poor is as much a charge upon the State as the care of

lunatics, or of prisoners, or even of our soldiers and sailors; and while the State has provided a Commission in Lunacy for one class, and a Home Secretary to take care of another class, and a War Department to provide for a third, so has the State provided a Poor-law Board to watch over the interests of the Poor. If the State has cruelly neglected the Sick Poor the fault is with the authorities at Whitehall in the first instance, and with the Boards of Guardians in the second instance; and the insolence, the arrogance, the ignorance, and the mismanagement of the latter might have been controlled by the former, if, instead of slavishly waiting upon public opinion, the Poor-law Board had gone in advance. As we have before remarked, we have no blame to cast upon the Board for its general administration of the Poor-law; but we unequivocally condemn its whole course of proceedings in reference to the sick, until very lately, when public indignation has been aroused by the record of individual sufferings and hardships. The Board now tries to avert the storm of indignation, which ought really to be directed against itself, by obliquely throwing the blame on the Local Boards, which have actually been encouraged in their misdoings by the ægis thrown around them by Government authority.

As to the expense of erecting suitable receptacles for the Sick Poor, and the difficulty anticipated in obtaining the funds, we utterly ridicule the idea. Within the last few years gigantic lunatic asylums and model prisons have sprung up in the very vicinity of the metropolis, and who has ever said a word against the cost of their erection? They have been built at the expense of the public, and without a murmur on the part of the tax-payers; and why, we ask, should there exist in a Christian country any difficulty in procuring funds for the comfort of the sick pauper, when they are readily granted for the lunatic and the criminal?

Notes on Current Topics.

THE MEETING OF THE MEDICAL COUNCIL.

WE understand that the annual general meeting of the Medical Council is fixed for Thursday, the 17th of May. Various objections have been urged against the period chosen, such as the facts that it will be in Whitsun week, that the Parliament will not then be sitting, and that the season will be so far advanced that there will be no chance of any success in legislative attempts. But it is to be hoped that the weather will be fine; and as two, if not three, opera houses will be open, and the white-bait will be in season, and many other attractions will, no doubt, present themselves, there is every reason to anticipate that the visitors to London will enjoy a pleasant holiday, the more pleasant as it will be at the expense of the Profession. As the week's sitting of the Council costs some fifteen hundred pounds, it might perhaps be asked what is likely to be the *quid pro quo* for this rather large expenditure, and the answer must be that no beneficial result can be expected. In fact, the Profession is utterly dissatisfied with the Act of 1858, which, instead of being a measure for the protection of the legitimate practitioner, is a mea-

sure for the protection of the quacks; and if any attempt were made to secure its real efficiency for the purpose which it pretends to aim at, the chief opponents to its amendment would be the quack fraternity, backed by the great mass of the members of the Legislature. There is not, we believe, the slightest chance that any improvement of the Act will be effected, at least while the present ministers remain in power, and our best wish to the Medical Council is that they may enjoy their holiday, and our hope is that they may spend as little time in talk as possible.

PARLIAMENT AND THE VACCINATION ACTS.

A BILL has just been introduced into the House of Commons, and has passed its second reading, having for its objects the consolidation and amendment of the statutes relating to vaccination in England. The bill contains some clauses which may, perhaps, be serviceable in promoting the practice of vaccination, but we are sorry to observe that the remuneration of the vaccinators is fixed at the former low rate, and that no payment is offered for certificates of vaccination granted by Medical men, whether public vaccinators or not. It is, of course, of little avail for the profession to interfere with the progress of this bill, as it is not very likely that their remonstrances will be successful; but we cannot help expressing our sense of the great impropriety and inexpediency of intrusting the superintendence of vaccination to the Poor-law Board and the local Poor-law Guardians. It is true that some of the Poor-law Medical Officers are also public vaccinators, but this is by no means necessarily the case, nor is it at all desirable that the practice of vaccination should be confounded or mixed up with the medical relief of the poor. A child who is vaccinated by a public vaccinator is not pauperised by the operation, and it is expressly stated that gratuitous vaccination is not a charity, but a necessary duty performed by the state. When we add to this very strong reason the still stronger argument that the Board of Guardians are wholly incompetent to superintend the performance of vaccination, and that the Poor-law Board is in no respect better qualified, we conceive that we have made out a strong case for the transference of the present power to other hands. Vaccination is a department of preventive medicine, and stands in no connexion with the administration of the Poor-law.

THE DISCOVERY OF THE TRICHINA.

THE question as to the discovery of the trichina in the human subject appears likely soon to be definitively settled, the paper of Dr. Cobbold, to which we alluded last week, having called forth some further explanations, all remarkable for their courteousness and their candour. But among the new claimants to the honour appears Mr. Thomas Nunneley of Leeds, who states that in April or May, 1832, he accidentally discovered what now appears to be the entozoon in question, in the muscles of the neck of a subject brought for dissection to the dissecting-room of Guy's Hospital. But Mr. Nunneley candidly admits that although he preserved the specimen of muscle for many years, he believed the parasite to be a species of *cysticercus*. Mr. Paget, who discovered the trichina in a subject at St. Bartholomew's in January, 1835, is equally modest and equally candid, and he gives a graphic and rather amusing account of carrying his specimen about in

search of a microscope to various great men of that period, but not finding the instrument in the possession of any of them except Robert Brown, the celebrated botanist, who, although no helminthologist, pulled the worm from its cyst. The trichina thus developed, but not yet described, was presented (in diagram) by Mr. Paget to the Abernethean Society, on February 6th, 1835, but it was nearly three weeks afterwards that Professor Owen, having received the specimen, detected its true nature, and described it at a meeting of the Zoological Society.

A MODEL WORKHOUSE INFIRMARY.

In a letter published in the *Times*, Mr. H. C. Tucker, C.B., announces himself as a Guardian of the parish of Marylebone, who was unable to obtain a hearing amidst the noise which prevailed at some period of the proceedings at the meeting for the improvement of Workhouse Infirmaries, and he states that he intended to show that, however true in general the denunciations against these establishments might be, the Marylebone Workhouse was an exception to the rule. The Infirmary of this Workhouse, we are told, is a light, cheerful building, looking upon a garden and a playground, and has as good a classification as any Hospital. There are male and female surgical wards, male and female medical wards, separate wards for admission of persons afflicted with insanity, rooms for permanent idiotics, imbeciles, and epileptics, lying-in wards and wards for children, with separate rooms for hooping-cough and measles. Three hundred and sixteen women were confined here in 1865, and only two died; and of two hundred and fourteen persons with mental afflictions, no less than one hundred and seven were cured. There is a paid head nurse, one midwife, four superintendents of idiots and lunatics (about one to fifty), and ten paid nurses. We do not question any of Mr. Tucker's statements, and we are further happy to record the great liberality of the Marylebone Guardians towards their Medical Officer, who, we are told, receives £950 a year—a rather handsome salary as times go. But what with the male and female surgical and medical wards, the three hundred and sixteen lying-in women, the two hundred and fourteen lunatics, besides the imbeciles, permanent idiots, and epileptics, and the children with hooping-cough and measles, the one Medical Officer must have his hands pretty full.

THE DEATH OF DR. CONOLLY.

THE death of Dr. Conolly, which took place on Monday week, although it will not surprise those who were aware that his health has lately been failing, will come like a shock upon the public and the profession, with whom his name has long been associated, especially in connexion with the treatment of the insane, whose present improved condition in asylums is in great measure due to Dr. Conolly's personal labours and to the influence of his writings. Dr. Conolly had arrived at the full age of three score years and ten, and lately presented the appearance of an invalid, looking even older than he actually was; but many now living can recollect him as a handsome and elegant man, with black glossy hair, when he first came to London in 1828, as the original Professor of the Principles and Practice of Medicine at the then University of London. This position, however, he did not long retain, and he returned to provincial practice, being

succeeded at the University by Dr. Elliotson; and Dr. Conolly having subsequently devoted himself to the special study of diseases of the mind, was appointed Medical Superintendent of the County Asylum, then newly established at Hanwell, where he acquired a large field of experience, and where he introduced and carried out many beneficial changes. After his retirement from that institution, he devoted himself to private practice, and became the proprietor or part-proprietor of more than one private asylum, with which he was connected at the time of his death. His decease, although not unlooked for as a probable contingency, was at last somewhat sudden, as he was seized with insensibility on Sunday, March 4th, and died on the following day.

THE WINES OF GREECE.

AMONG the light and cheap unadulterated wines which the policy of the present Chancellor of the Exchequer has introduced into common use in this country, some of the most promising are those of Greece, which Mr. Denman, of 20, Piccadilly, is now importing. It is well known to all who are familiar with the works of the classical writers that the wines produced on the continent of Greece and the adjacent islands have long been celebrated, not only for their pure and vinous flavour, but for their strength, which, so far from diminishing, increases with age. The public have now an opportunity of making themselves acquainted with these wines, and at a very cheap rate, the price of an excellent red wine, of a decided Burgundy flavour, being only about sixteen shillings a dozen. Those who expect to find in these wines the brandied flavour and the syrupy sweetness of the manufactured ports and sheries brought into the English market will of course be disappointed; but those who can appreciate a pure and unadulterated liquid obtained by the action of fermentation on the simple juice of the grape will obtain an article at once wholesome, invigorating, and refreshing, and at such a price as to bring it within the reach of all. The principal wines are those of Santorin, a volcanic island, almost entirely devoted to the cultivation of the grape; of Patras, on the isthmus of Corinth; and of Athens, which yields both the Mont Hymet, obtained, as its name implies, from the vicinity of the celebrated Hymettus, and the Kefesia, named from the no less celebrated river Cephissus. The St. Elie, or wine of night, so called because the vintage takes place during the night, and the grapes are hidden beneath the leaves of the vine, is an almost colourless wine, developing by time the flavour of Amontillado, while the Mont Hymet is a red and dry wine, of a Burgundy character. Mr. Denman has done good service by presenting these wines to British consumers, and the more they are known the better will they be appreciated, more especially as they improve by being kept. They are almost as cheap as beer, and form excellent dinner wines, being adapted either for sipping in wineglasses or for mixing with water and being used as beverages.

BRAGG'S CHARCOAL POWDER AND BISCUITS.

THE well-known chemical properties of charcoal as an absorbent, deodoriser, and disinfectant, have led to the use of this substance as a medicinal agent, taken internally in some disordered conditions of the stomach, especially those

characterised by flatulence and heartburn. Charcoal is quite tasteless, undergoes no change in the stomach, and produces no deleterious effects whatever. As an internal medicine it has been brought into notice chiefly by Mr. James Bird, who has written a useful monograph upon its application and the cases of illness for which it is adapted. In order to introduce it into the system in an agreeable form, Mr. Bragg, of Wigmore-street, Cavendish-square, has invented a biscuit, which contains the purest vegetable charcoal, so mixed with the ordinary ingredients of a biscuit, that, except for the colour, it would be impossible to know that there was any peculiarity in its composition. We consider this method of administering charcoal to be the most ingenious hitherto devised; but Mr. Bragg has also prepared a pure vegetable carbon in impalpable powder, which may be taken by itself in water, if this mode of administration should be preferred.

VACCINATION BILL, 1861.

The following is the epitome of the Vaccination Act referred to by Mr. Griffin in his letter, and about to be amended by Mr. Bruce's Bill:—

Clause 1.—Repeal of former Acts.

Clauses 2 and 3.—Guardians to have power to divide unions or parishes into districts, subject to the approval of the Poor-law Board.

Clause 4.—Qualification of public vaccinator to be prescribed by the Lords of Her Majesty's Council, who are to make regulations to secure efficient performance of vaccination, or the provision and supply of vaccine lymph by public vaccinator.

Clause 5.—For every successful vaccination at an appointed station, situated at or within two miles of the residence of the vaccinator, or in the workhouse of the union or parish, not less than 1s. 6d., and beyond that distance not less than 2s. 6d. [It should be altered to 2s. 6d. and 3s. 6d. for the first 300 cases in any one year, and above that number to 1s. 6d. and 2s. 6d.—R. G.]

Clause 6.—Conditions may be imposed in contracts to secure the fulfilment of the provisions of this Act on the part of the vaccinator, and guardians shall provide all stations at which the vaccination shall be appointed to be performed other than the surgery or residence of the public vaccinator.

Clause 7.—No payment for revaccination if previously successfully vaccinated unless Lords of Council issue regulations on the subject, and then only two-thirds of the fee allowed for primary vaccination.

Clause 8.—Contract not valid unless approved by the Poor-law Board, and even then may at any time be determined by them.

Clause 9.—No payment to be made unless contract approved by Poor-law Board.

Clause 10.—No public vaccinator to be paid for vaccination out of his district.

Clause 11.—In districts with scanty population guardians may provide for the attendance of public vaccinator after intervals exceeding three months. Between the periods parent of child exempt from penalties. [Under this provision, how is the inspection to be made or the supply of lymph to be kept up?—R. G.]

Clause 12.—Guardians to give notice of alteration of districts.

Clause 13.—Registrar-General to provide forms.

Clause 14.—Registrar of Births to give notice to parents or others, where and when a child may be vaccinated.

Clause 15.—Child to be vaccinated within three months after birth, unless death, &c., of parent, then four months allowed.

Clause 16.—Child to be taken on the seventh day fol-

lowing vaccination to public vaccinator for inspection, and if he sees fit he has power to take from such child lymph; if vaccination has been unsuccessful, vaccinator may direct child to be forthwith revaccinated.

Clauses 17 and 18 make provision if the child is not fit for vaccination, and the delivery of a certificate by the public vaccinator or medical practitioner, which shall remain in force for two months, and be renewable every two months. [No fee for this.—R. G.]

Clause 19 determines the continuance of the two months' certificate by saying if a child has been more than once unsuccessfully vaccinated, and the vaccinator shall find he is insusceptible of vaccination then a certificate to that effect shall be granted, and the parent shall thenceforth not be required to cause the child to be vaccinated. [No fee for this.—R. G.]

Clause 20 provides for the furnishing of a certificate to be forwarded to the registrar where the birth was registered (if known to him), or else to the registrar of the district where child was vaccinated, within twenty-one days of its successful vaccination, and duplicate certificate to the parent of the child. [No fee for this.—R. G.]

Clause 21 provides that no fee shall be paid the public vaccinator for these certificates. [This should be reversed. R. G.]

Clause 22 provides that the parent of the child shall transmit the certificate if the medical practitioner be not a public vaccinator.

Clause 23 provides that the registrar shall keep a book wherein to enter vaccinations, and for every search therein 1s. shall be paid and for every copy 6d.; but no fee shall be paid for a search by a public vaccinator, or any officer of the guardians authorized by them to make such search, or any inspector appointed by the Poor-law Board or Lords of her Majesty's Council; the registrar shall also receive a fee of 1d. for every notice to vaccinate when he registers a birth, and 3d. for every certificate of vaccination he shall have registered, and 1d. for every certificate of vaccination where he has not registered the birth.

Clause 24.—Registrar to make out in duplicate quarterly accounts and to be paid fees by boards of guardians.

Clause 25.—Vaccination declared to be not parochial relief.

Clause 26.—Guardians to be paid all reasonable expenses for notices to be printed and circulated, and compensate any officer appointed by them to prosecute persons charged with offences against this act, or otherwise to enforce its provisions.

Clause 27.—Parents or others neglecting to take child to be vaccinated, or after vaccination to be inspected or revaccinated and reinspected, shall be guilty of an offence, and be liable to be proceeded against summarily, and upon conviction to pay a penalty not exceeding 20s.

Clause 28.—Vaccinator and parent neglecting to transmit certificate liable to a penalty not exceeding 20s., and in the case of false certificates to be guilty of a misdemeanour, and punishable accordingly.

Clause 29.—Justices may make an order for the vaccination of any child under 13 years of age within a given time, and if at the expiration of the time the child has not been successfully vaccinated, or is unfit, &c., the parent or other person shall be liable to a penalty not exceeding 20s., and it shall be no answer to the making of such order that he shall have been previously convicted of an offence under this or any other act relating to vaccination.

Clause 30.—Penalties upon persons inoculating with small-pox.

Clause 31.—Penalty, not exceeding £5, for wilfully exposing small-pox patients, or carelessly conveying them in public conveyances.

Clauses 32, 33, 34, and 35, relate to the statutes now in force, notices and interpretation, clauses and titles, followed by forms A, B, C, and D, which will require altering, especially the medical titles, which are only M.D., L.A.C., or F.R.C.S.

Parliamentary Intelligence.

HOUSE OF LORDS.—MARCH 5.

THE CATTLE DISEASES PREVENTION ACT.

THE DUKE OF BUCKINGHAM called attention to the fact that the police were unable in certain districts to comprehend the provisions of the Cattle Plague Bill.

EARL GRANVILLE was understood to say that attention would be directed to the subject.

THE CATTLE PLAGUE BILL.

EARL GRANVILLE stated, as several alterations had been made in the Cattle Plague Bill, he wished to inform their Lordships that these would be printed before they went into committee of the whole House. But in order to avoid any further loss of time, he proposed that their Lordships should go into committee on Thursday, and that the standing orders should then be suspended, in order that the Bill might be carried through all its stages that day.

MARCH 6.

THE CATTLE DISEASE.

EARL GRANVILLE read a report from Professor Simonds of some experiments with Mr. Worms's mode of cure that had been made on Baron Rothschild's cattle, at Mentmore, and from which he said he was sorry it appeared that these experiments were comparatively a failure.

MARCH 8.

THE CATTLE PLAGUE BILL.

The House went into Committee upon the Cattle Plague Bill.

Considerable discussion took place upon various clauses, and several amendments were introduced, but the principal debate arose upon a clause giving to the Privy Council a discretionary power to discontinue the compulsory slaughter of cattle after the passing of the Act.

THE DUKE OF RICHMOND objected to the clause, and proposed to amend it by deferring the discretionary power until after the 15th of April, the date fixed by the 12th section of the Cattle Diseases Act.

LORD GRANVILLE supported the amendment, believing that it was desirable that the experiment of compulsory slaughter should be tried for a few weeks.

THE DUKE OF MARLBOROUGH believed that it would be impossible to get the local authorities to carry out a system of compulsory slaughter, which had originated in a moment of panic, and which would be more injurious than the disease which it was intended to meet. He should recommend that a discretionary power be given to the local authorities, to order compulsory slaughter or not, as they might deem advisable in the circumstances of their respective localities.

AFTER some remarks from the Duke of Argyll and Lord Kinnaid in support of the clause, and from support of Lord Spencer in the amendment, the Committee divided, when the amendment was carried by a majority of 57 to 24.

THE DUKE OF MARLBOROUGH then proposed a clause giving immediate discretion to local authorities to suspend the compulsory slaughter of cattle which were recovering, but, after a brief discussion, the clause was negatived by 50 to 24.

The only other clause which led to any debate was one proposed by Lord Lichfield, the effect of which was to close all markets and fairs for a considerable time to come.

LORD GRANVILLE objected to the clause, and pointed out the inconvenience that would arise from restraining the action of the Privy Council.

LORD SPENCER supported the clause, which, upon a division, was carried by 24 to 22.

The remaining clauses were agreed to, and, by a suspension of the Standing Orders, the Bill was read a third time and passed.

HOUSE OF COMMONS.—MARCH 1.

THE DWELLINGS OF THE WORKING CLASSES IN THE METROPOLIS.

MR. T. HUGHES postponed for a week his motion relative to the adoption by the House of certain standing orders with reference to the removal of the dwellings of the working classes in the metropolis in connexion with the construction of railways and public buildings.

MARCH 3.

THE CATTLE PLAGUE.

MR. WALDEGRAVE-LESLIE moved an address for a return

of the number of cattle slaughtered in each county and borough in England in obedience to the directions of cattle inspectors, acting under the order of the Privy Council of the 26th day of August, 1865, between that date and the 23rd day of November, 1865, when the said order was revoked; a similar return for each county and borough in Wales; and a similar return for each county and borough in Scotland.

Agreed to.

MARCH 6.

COMMONS NEAR THE METROPOLIS.

MR. COWPER gave notice of his intention to move for leave to bring in a bill with respect to the commons in the neighbourhood of the metropolis (hear, hear).

MR. HIBBERT moved for leave to bring in a Bill to permit capital punishment to be carried out in the interior of prisons.

Rather an interesting debate followed, in the course of which

SIR G. GREY, while declining to oppose the bill, suggested that it would be better to wait until the Government Bill on the subject was brought in. He intimated pretty distinctly that the Government Bill would contain provisions to carry into effect the proposals of Mr. Hibbert's Bill.

Leave was given to introduce the measure.

RETROSPECT OF MEDICAL JOURNALS.

10TH MARCH, 1866.

THE *Lancet* of the above date devotes an article to the consideration of compensation for railway accidents. There is no doubt but that swindling goes on to a great extent in cases of this nature; deception on the part of the fortunate plaintiff and personal feeling on the part of the jury often enable persons to mulet a railway company to no small amount. So much is this the case that there is an inclination on the part of the railway companies to settle these claims out of court. Such accidents as are accompanied by any visible or tangible symptom, as fracture or wound, are sure to be considered fairly. We consequently fail to observe in the cases reported in the newspapers any litigation about them, but where the symptoms are of a nervous type, and the nature of the accident depends on the statement of the individual, there is naturally some incredulity to be expected, and hence the merits of the case are laid before a jury with the usual concomitant phenomenon of conflicting medical testimony. More than ordinary attention is drawn to this subject now, in consequence of some of the leading metropolitan railways having applied for Acts of Parliament to limit the amount of liability, at least so far as parliamentary trains and the different classes of passengers are concerned. We believe opposition will be given to such a measure, on the ground that it would be desirable to consider the expediency of framing an act of Parliament which would refer to all companies, and not give to any individual company a preference. Dr. Buzzard is engaged in the very difficult task of collecting together instances of nervous affections produced by railway accidents. It is the first attempt at any such compilation, and we are sure that, when published, it will form a very valuable addition to the medico-legal library.

The value of statistics is beginning to be looked on as accessory and not *probative* of any particular object.

Reference is made to the case of the Guardians of the York Union and Dr. North. This gentleman seems to be more fortunate than others in his masters; they acknowledging his increasing services and usefulness, have gradually increased his pay within twelve years from £40 to £120 per annum. It is quite refreshing to find such rare case of magnanimity "cropping out" occasionally, hence it is a pity that the guardians should be balked by Dr. Smith, the new Poor-law Inspector.

Objection is made to Dr. Buchanan's views as regards the utilizing of the bodies of criminals for the purposes of scientific experiment before and after death. We should not forget that on the Continent some medical questions have been set at rest by the examination of criminals, who

did not think bad of bartering a chance of life for some temporary painful operation.

Dr. Grey has been elected Coroner for a division of Yorkshire.

It is worth bearing in mind on the part of those about competing for Indian appointments, that those surgeons who were gazetted on the 2nd inst. were hurried off on the 4th. This certainly indicates a want of men.

We find letters from Mr. J. Paget, Mr. Wilks, and two Presidents of the Abernethian Society, in reference to the first discovery of trichinæ in human muscle. It will be remembered that Mr. Paget (then a first year's student) was the first to lay them before the public.

Dr. Goolden gives some cases in which the inhalation of oxygen gas, in certain forms of disease resulting from debility, was attended by marked benefit.

Dr. Brown-Séquard's lectures on the diagnosis and treatment of functional nervous affections are continued.

We are sorry to see Dr. Forbes Winslow's paper on the subject of the Medical evidence given before the Royal Commission on Capital Punishment. At first sight he would appear to be jealous of Drs. Hood and Tuke, who gave evidence before that body. Every one knows that Dr. Winslow's opinions are extreme on the subject of moral insanity; but even admitting this, we were not prepared for the hairsplitting analysis of Dr. Tuke's evidence. He appears more in the light of a special pleader than a scientific man in search for the truth.

Mr. H. Power relates a case of death from spasmodic stricture of the œsophagus, in which no disease could be detected after death.

Dr. Williamson describes a case in which Dr. Tyler Smith attempted to perform ovariectomy, but was obliged to desist. A large abscess formed in the abdomen, and the patient completely recovered.

At St. George's Hospital a case of poisoning by two drachms of oil of almonds has occurred.

The *Medical Times and Gazette* for the 10th inst. draws attention to the daily life of a naval surgeon, which it must be allowed is sufficiently monotonous; the list of instruments to be furnished by the assistant-surgeon comprehends but two silver and two gum-elastic catheters, no aneurism needle, but twelve lancets and six pewter syringes.

In the French Senate Cardinal Archbishop Donnet has been reproducing instances of persons buried alive; it is clear that some such have happened from time to time, but not in the number that the vulgar would have us believe.

M. Alphonso Guérin's method of treating anthrax by subcutaneous incision, has been tried by M. Gosselin, who has given up the ordinary crucial incision, as indeed has almost every modern surgeon. Velpeau is still fond of extensive incisions, as is also Nelaton, although the latter at one time renounced them.

Mr. W. E. Porter describes a new method of reducing dislocation of the shoulder by manipulation.

One of the most practical and useful papers we have read for some time is that by Mr. J. Hutchinson, on injuries of the head and neck of the humerus. He alludes to the fact, that after fracture through the upper epiphyseal line we have a deformity resembling that attending unreduced dislocation. This is a very important point; he also divides fractures in this neighbourhood into those through the tuberosities and below them, thus very properly setting aside that absurd division which included fracture through the anatomical neck. We would recommend every hospital surgeon to peruse this paper.

Dr. Richardson makes some remarks on the new method of producing local anesthesia. As yet the only improvement made in the instrument is the substitution of a compound jet. We have heard that the sale of the instrument has been unprecedented.

In the *British Medical Journal* of the 10th inst., on the subject of village hospitals and the remuneration of the medical men so attending, we find the following:—

"It is very refreshing to find a man in Dr. Thompson's position who speaks out thus against the folly and wrong-

ness of medical men working without due remuneration. On this score, also, we may mention with pleasure that, at the annual meeting of the Royal Medical and Chirurgical Society, Dr. Alderson, in his excellent presidential address, spoke in no measured terms against the cruel system of gratuitous medical services. We sincerely hope that the eyes of the profession are becoming opened at last to this monster evil; that they are beginning to see the matter in its true light—in fact, to acknowledge that gratuitous medical services are only another term for medical competition."

We find another successful case of amputation at the hip-joint mentioned from the practice of Dr. Packard of Philadelphia. The operation was secondary to an original amputation through the lower third, followed by hæmorrhage and necrosis.

Dr. Althaus's lecture on hysteria is a very sensible *resumé* of the subject. He does not believe in the uterus as the origin of the disease, but that the affection is due to an excitable condition of the nervous system. We recollect when a student having been reproved by our professor of medicine for talking of hysteria in the male; we were told to call it hypochondriasis.

THE WORKING OF THE ENGLISH POOR-LAW SYSTEM.

THE Rev. Sir LOVELACE STAMER, Rector of Stoke-upon-Trent, in addressing the Guardians of that Union, made the following observations, which we extract from a local paper:—

"Under the present system the medical officers were paid by small fixed salaries, altogether out of proportion to the work they had to do, and extra medical and vaccination fees. The tendency of this was to make medical officers eager to secure as many extra fees as they could get. And this was quite natural; for they all knew very well that if an employer had clerks or others who had small pay, if there was some other allowance of payment for extra work, they would try to do that work. The present system of payment to the medical officers was, he considered, disadvantageous both to the parish and to the poor. In cases in which the medical officer had to decide between a long course of treatment to effect a cure and a capital operation, it was most likely that he would resort to the capital operation rather than have the trouble of the prolonged course of treatment. Then he did not know what check they had upon the medical officers, and he was not aware of any control they had over the expenses under the present mode of payment, and, on that ground, he thought the system was not satisfactory. From a consultation he had had with a gentleman well qualified to give an opinion on such a matter, he fully believed that it would be much better to pay the medical officers by a fixed salary, and not allow any extra fees only in cases of vaccination and midwifery; in the latter he thought it would be especially desirable to retain the present system of allowing an extra fee, as the poor would then be more likely to get good attention."

These remarks are, we think, perfectly uncalled for, and weigh with a special weight of injustice from a gentleman of the rank and profession of the Rev. Baronet. Unless the Union to which the speaker belongs be specially unfortunate in its Medical Officers, and we have no reason to think it is, the insinuation that they make their conscience and their duty subservient to their own interests is most uncalled-for and unworthy. It is a gross libel on the Poor-law Medical Officers of England to say that, "in cases where the Medical Officer had to decide between a long course of treatment and a capital operation, it was most likely that he would resort to the capital operation rather than have the trouble of the prolonged course of treatment." If the Reverend Gentleman does not think that Medical Officers should be trusted to adopt the most judicious treatment, he will not

be in a better position by placing them under a fixed salary. But this inuendo is especially discreditable, it being only the peg on which to hang a reform, the real reason for which is behind in the subsequent statement of the Rev. Baronet that if fixed salaries were given, "there would be a considerable return from the Consolidated Fund."

Let the Stoke Guardians, by all means, relieve themselves at the expense of the Consolidated Fund, but let them not look for an excuse for so doing in the practice of their Medical Officers.

THE CHARGE OF MANSLAUGHTER AGAINST AN ASSISTANT.

We are requested to publish the following extract from the *Newcastle Daily Chronicle*, leaving our readers to judge of their pertinence as regards the charge against Dr. Richardson. It will be remembered that a verdict of manslaughter was returned against Mr. Richardson's assistant for omitting to catheterise a patient who died in consequence:—

TO THE EDITOR OF THE DAILY CHRONICLE.

SIR,—In your report of the inquest at Middlesbro' yesterday, in to-day's publication, I am said to have made to the coroner the remark that "It appeared to me that people could be poisoned at South Stockton, but it was manslaughter at Middlesbro'." What I really said to the coroner was "That a child could be poisoned at South Stockton by the gross ignorance of a young medical man, and a South Stockton jury acquitted him of having committed any crime; whilst a Middlesbro' jury had convicted a talented and experienced medical man of manslaughter, who had faithfully performed his duty to his patient." I may add my only fear is that no judge will allow such a paltry contemptible case to go to a jury, as if he does, the most shameful conspiracy to destroy the character of an excellent practitioner will be fully exposed.—I am, Sir, yours faithfully,

WILLIAM RICHARDSON.

Stockton-on-Tees, Jan. 23, 1866.

THE SERIOUS CHARGES AGAINST THE MIDDLESBRO' PARISH AUTHORITIES.—The usual fortnightly meeting of the Stockton Guardians was held in their offices, High-street—the Chairman (Mr. Marshall Fowler) presiding.—The Chairman said a report had reached him that morning that an unfortunate affair had occurred at Middlesbro'. There had been an inquest held, and a verdict of manslaughter returned against one of their medical officer's (Mr. Richardson) assistants.—Mr. Fallows said he had not had time to make himself fully acquainted with the matter, but he understood that a question as to the mode of treatment to the man used by Mr. Richardson's assistant had arisen, and a verdict of manslaughter had been returned. He was desirous that the matter should be referred to the Middlesbro' Committee of Guardians, in order that they might make themselves fully acquainted with the circumstances of the case, and report to the Board at their next meeting. The medical officer of the Guardians was involved in the matter, and it was a question which fairly called upon the Board for investigation.—Mr. Wm. Richardson, of Stockton, would be glad to second that motion. He was present at the inquest, and was satisfied that there was nothing at all in the matter; there was not a tittle of evidence against the medical officer.—Mr. Fowler: What did they give their verdict upon, then?—Mr. Richardson: It shows the absurdity of appointing an attorney instead of a medical man as coroner.—Mr. Fowler: But what was the cause of death?—Mr. Richardson: He died, sir, of retention of urine and extravasation of blood from the urethra. I have no hesitation in saying that Mr. Simpson simply did his duty.—Mr. Richardson: No, sir; but I should like the matter inquired into.—Mr. Fowler: Well, we should stop the assistant from attending any other patient.—Mr. Richardson: That has already been done, sir. Mr. Simpson was a pupil of mine for seven years.—Mr. Fowler: Well, the matter had better be referred to the committee,

Correspondence.

POOR-LAW MEDICAL RELIEF AND VACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall feel obliged by your allowing me space to inform the Poor-law Medical Officers that a Bill has been introduced into the House of Commons by Mr. Bruce and Mr. Baring, entitled "A Bill to Consolidate and Amend the Statutes relating to Vaccination in England." I wrote to Mr. Bruce a few days since, enclosing a copy of the plan proposed by us in 1861, which will be found in the pamphlet entitled, "Evidence on Poor-law Medical Relief, 1861," page cxii. A few copies of this pamphlet I have still in hand, and shall be happy to send one to any gentleman on receipt of twelve postage stamps. Mr. Bruce's Bill is a great improvement upon the Acts now in existence, and contains penalties in sufficient abundance; but the rewards to the Medical Officers stand as they are in the present Acts. The 1s. 6d. and 2s. 6d. ought to be altered to 2s. 6d. and 3s. 6d. for the first 300 cases vaccinated by an individual Medical Officer in any one year, and for all above that number the 1s. 6d. and 2s. 6d. may remain. The Act expressly provides for the granting of certificates by medical men, whether public vaccinators or not, but there is to be no payment. Thus a medical man may vaccinate a child half a dozen times unsuccessfully, and be compelled to give as many certificates, but he is to have no payment either for vaccination or certificates. I recommend that certificates should be paid for at 6d. each, which would give the profession about £13,000 per annum. The Act should be perused by the Poor-law Medical Officers, who are for the most part public vaccinators; it can be procured through the medium of a bookseller or an M.P. In order, however, to save time, I have drawn up an epitome,* which is at your service should you be able to find space for it. I should strongly recommend every public vaccinator to write to his M.P., and endeavour to get some of the clauses amended, particularly those relating to payment, for as they now stand it is not worth a District Medical Officer in a small and thinly-populated district taking the trouble to carry out the provisions of the Act, and as a consequence small-pox in this kingdom will never be eradicated.—I am,

RICHARD GRIFFIN.

12, Royal-terrace, Weymouth, March 3, 1866.

List of subscriptions received during the last week for the Poor-law Medical Reform Association by Mr. Griffin:—

Burrows, S., South Molton, 5s.; Hinton, J., Bath, 10s.; Boyle, T. St. Columbe Major, 5s.; Carter, C. H., Pewsey, 10s. 6d.; Moreton, J. E., Gt. Boughton, 10s.; Ransome, R., Cambridge, 10s. 6d.; Cordwint, G., Taunton, 5s.; Brown, G. D., Ealing, 5s.; Goold, H. B., Portsea Island, 5s.; Simpson, T. B., Portsea Island, 5s.; Fowler, R., London, East, 5s.; Hurst, A. D., Islington, 5s.

By Mr. Prowse, Amersham:—

Jay, F. F., Depwade, £1; Hovell, D. de Berds, Hackney, £1 1s.; Hewitt, T. S., East Hampstead, 10s.; Hill, W. R., Lymington, 5s.; Chinery, E., Lymington, 5s.; Barrett, A., Freebridge, Lynn, 5s.; Hutchinson, J., Prestwich, 10s. 6d.; Hitchins, C. V. Axbridge, 5s.

THE LATE PROFESSOR SCHREDER VAN DER KOLK.

The following letter, addressed to the Editor of the *Reader*, appears in that journal for February 3rd:—

"7, South Anne-street, Dublin, January 16, 1866.

"Sir,—My attention has been called to the following passage, which appears in your impression of the 23rd December, 1865, p. 714:—

"C. Schroeder van der Kolk, son of the great anatomist, has just published a work entitled "Soul and Body" (Seele und Leib), in which the endeavours to prove that what is called soul is simply the manifestation of brain, just as digestion is the function of stomach. He says, memory, imagination, reason, and even volition, are but the result of physical actions, or electro-molecular, excited by the operation of perception—the contact with the outer world."

* See page 260.

"It is true that Dr. H. W. Schröder van der Kolk, son of the late distinguished anatomist and physiologist, and now Professor of Physics at Zutphen, in Holland, has edited essays entitled 'Ziel en Ligchaam' (Soul and Body), and that a German version of this work has recently been brought out by Vreweg, but the essays are from the pen, not of the son, but of the late Professor himself. I am assured that these essays, however, contain no theory of the action of the brain; what is stated in the paragraph I have quoted from your pages refers clearly to the 'Handboek van de Pathologie en Therapie der Krankzinnigheid' (Manual of the Pathology and Treatment of Insanity), a fragment published after the author's death, and subsequently translated by Theile into German. But neither are the views contained in this work correctly stated in the above paragraph. The words 'just as digestion is the function of the stomach,' strongly recall expressions of Vogt, but are not to be found in the writings of van der Kolk. As it fell to my lot to translate some of the works of the late distinguished Professor, and as I was privileged during the editing of my translations to enjoy a lengthened correspondence with him, I am enabled to say that he held opinions the very opposite of those implied in the passage just brought forward. I hope it will not occupy too much of your space to allow me to quote, in support of this statement the following passage from my translation of S. van der Kolk's work on 'The Minute Structure and Functions of the Spinal Cord,' a translation (published by the New Sydenham Society, London, 1859) which was carefully revised and corrected by the Professor himself. The author, speaking of the harmonization of movements, says, at p. 74:—

"Some, as E. Pflüger, observing such phenomena, have been misled into assuming a sort of voluntary power of mind in the spinal cord, an error attributable solely to want of examination of the ingenious arrangement of the tissue and of the structure of the cord, in which all these harmonized movements appear to lie hidden, pre-arranged in the several combinations of the groups of ganglionic cells, and ready to be excited by any stimulus, whether voluntary or reflex, so that they are produced just as the harmonic tones of a piano under the fingers of the player. Such a view is sufficient to excite amazement at the ingenious nature of all these arrangements and wonderful combinations, but, it is conceivable, and in my opinion not so difficult to imagine; while the idea of volition in the spinal cord, without consciousness, with the entire rejection of the existence of a soul, as Pflüger suggests, is an absurdity not to be thought of. On the contrary, the deeper we penetrate into the knowledge of the mechanism of our body, the more we shall be convinced that the whole is arranged as a perfect minister of our spirit and of our will, in which both the amazingly correct insertion, size, and combination of the muscles, and certainly not less the combination of the ganglionic groups, whereby these muscles are harmoniously and suitably moved, are calculated with incomprehensible wisdom and fulness of purpose."

"The sentiments expressed in the foregoing quotation will, I trust, be sufficient to defend their author from the imputation of any leaning towards materialism. I trust, therefore, Sir, you will allow me, as the friend and constant correspondent, during many years, of the late Professor Schröder van der Kolk, to show by an example what the real tendency of his writings and teaching was, as it is possible that a contrary inference might be drawn from the paragraph which found its way into your number of the 23rd December last.

"I have the honour to be, Sir, your obedient servant,

"WILLIAM D. MOORE, M.D. Dub., M.R.I.A."

MEDICAL DEPARTMENT OF THE UNITED STATES

THE Surgeon-General has just published a circular for the information of the medical officers of the army. The circular comprises reports from Brevet-Lieutenant-Colonel Otis, having charge of the surgical, and Brevet-Major Woodward, having charge of the medical history of the rebellion. From the surgical reports it appears that complete registers of the number of wounded were in course of preparation, in which over 87,000 cases of wounds and 17,000 surgical operations have been recorded up to September, 1865, the work of registration being still far from complete. The number of wounds received cannot practically be now determined with accuracy, though data for an approximate estimate are accessible. In the British army in the Crimea during the entire war there were 12,094 wounded and 2755 killed, or a total of 14,849. In the French army in the Crimea, of a total effective force of 309,268, according to the report recently made by M. Chenu, there were 39,868 wounded and 8250 killed, or a total of 48,118, although in his report of injuries of different regions M. Chenu records but 26,681 cases. In our late war the monthly reports from a little more than half the regiments in the field give for the year ending June 30, 1862, an aggregate of 17,496 gunshot wounds. The reports from rather more than three-fourths of the regiments for the year ending June 30, 1863, give a total of 55,974 gunshot wounds. The battle-field lists of wounded for the years 1864-65 include over 114,000 names. But these returns are to be completed by collating with them the reports of general hospitals where many wounded were received, whose names the recorders of field hospitals or regimental medical officers failed to obtain, and by adding the names of those killed in battle. In comparing the numbers of cases of some important injury, as, for example, gunshot fractures of the femur, it is found that in the French Crimean army there were 459 such injuries, and in the English army 194, while over 5000 such cases have been reported to this office. Or if one of the major operations is selected for comparison, as excision of the head of the humerus, the

Crimean returns give 16 of these excisions in the British and 38 in the French army, but the registers of this office contain the detailed histories of 575 such operations. The medical staff that served in the late war was composed of a surgeon-general, one assistant-surgeon-general and medical inspector-general, 16 medical inspectors, 170 surgeons and assistant-surgeons of the regular army, 362 volunteer staff surgeons and assistant-surgeons, 3000 regimental-surgeons and assistant-surgeons of volunteers, 2500 acting-assistants-surgeons and physicians serving under contract, and six medical storekeepers. The second report, by Major Woodward, contains an outline of the material collected for the medical branch of the history. The mortality from disease alone was 48 and 7-10ths per 1,000 of mean strength for the first year of the war, and 65 and 2-10ths for the second. Total number of deaths from disease reported for first year, 14,183, and 42,010 for the second. These figures do not include those who died while absent as prisoners of war or after having been discharged the service for disability. The number constantly sick was about 10 per cent. of the strength. The total number of cases treated by the medical department, including wounds and injuries, was 878,918 during the first year, and 1,711,803 during the second. The most fatal disease was camp fever, of which there were 213,260 cases, and 19,459 deaths during the two years; next comes diarrhoea and dysentery, 725,675 cases and 11,560 deaths; then inflammation of the respiratory organs, 304,284 cases and 8090 deaths. Venereal diseases were much less frequent than the experience of other armies would have led us to expect. Still, 84 men in every thousand suffered during the first year, and 65 during the second, the total number of cases being over 39,000. Twenty-eight thousand six hundred and twenty discharges for disability were reported during the first year, or about nine per cent. of the strength of the army. The report concludes with a sketch of the hospital system. It appears that at the *maximum* there were 202 general hospitals with 136,894 beds for patients. During the war over a million patients were treated in these, of whom but one in 12 died. Dr. Woodward says never before in the history of the world has the mortality in military hospitals been so small, and never have such establishments so completely escaped from diseases generated within their walls. Incomplete reports for the first year of the war from troops in the field and in garrison represent an average strength constantly present during the year of 281,117 men; in hospital, constantly present, 9759 men; total, 290,936, among whom were 14,183 deaths from disease. The number of deaths recorded is much less than the real number, and does not include prisoners of war and other absentees. For the second year, in field or garrison, 598,821; in hospitals, 45,687; total, 644,508, of whom there were 42,010 deaths from disease.—*New York Times*.

THE ADMINISTRATION OF THE POOR LAW.—Mr. H. B. Farnall, C.B., the Commissioner of the Poor-law Board for the inspection of the metropolitan district, attended the meeting of the guardians of the Greenwich Union, for the purpose of conferring with them as to their mode of administering the poor law. Mr. Carter occupied the chair. The Commissioner said the average rates in that union, comprising Greenwich, Woolwich, and Deptford, amounted to 2s. 2½d., while an average rate which would cover all the expenses for the poor of the metropolis would only amount to 1s. 2d. 9-10ths. He felt it his duty to suggest that there were means by which they might lower the rating in the union. Their workhouse, in his opinion, was overflowing. In it there slept on their previous night 938 persons, and of these 938 as many as 810 belonged to the temporarily disabled, old, and infirm classes. He did not think it was a fit place for them. Would not the great majority of them be happier and less costly in their own homes? The relieving officer and the medical man no doubt got rid of cases easily by sending them to the workhouse, and were tempted to do so; but this was a course which he should like to see stopped. It must be remembered that the average cost of a person in the house was 3s. 6d. a week, and this taking the baby at the breast with the others, while in a sick case the cost was not less than 6s. a week. There were 40 pauper nurses to look after the sick and infirm, and not a single paid nurse; and this, doubtless, was looked upon by the guardians as a great advantage, but it was not, as he could prove to them.

Scientific Societies.

ROYAL SOCIETY OF LITERATURE.—Feb. 21.—Sir Patrick Colquhoun, LL.D., in the chair.—Mr. Vaux read a paper, communicated by Col. Alexander, C.B., 'On the Character Life, and Opinions of Confucius,' wherein the history of this remarkable sage was traced out with great care from the original Chinese documents.—The Rev. M. E. C. Walcott gave an interesting account of the Chartulary of Lanercost Abbey, in Cumberland, now in the possession of the Dean and Chapter of Carlisle. This Chartulary is stated to be a transcript of the original manuscripts formerly at Naworth Castle, and was presented to the Library of the Cathedral Church, in 1777, by J. Hawksdale, Esq. The monastery of Lanercost was founded in A.D. 1116, by Robert de Vallibus (or Vaux), who held the Barony of Gillesland during the reign of Stephen.

ETHNOLOGICAL.—Feb. 27.—J. Crawford, Esq., President, in the chair.—The papers read were:—'On the Origin and Progress of Written Language,' by Mr. J. Crawford. The author made an elaborate outline of the origin and spread of languages over various parts of the earth, attributing the numerous existing languages to the separate inventions of distinct races. Of the ancient Europeans, he remarked that while Asiatics had early designed many alphabets, it was a most remarkable case that no European race, from the Euxine to the Atlantic, or from Greece to Scandinavia, had ever invented one. It might be presumed that no European race had reached that point of civilization at which written languages are invented, before the time when a foreign phonetic writing was presented to them and adopted.—'On the Somali Race,' by Col. Rigby. The Somali inhabit the north-eastern portion of Africa between the Straits of Babelmandeb and Cape Guardafui, and thence as far south as the Equator. They differ from all other African races in feature, language and customs. Up to this day the greater part of their country remains unvisited. They are a pastoral race, having large herds of cattle and flocks of the doomba, or fat-tailed sheep. In person, they are tall and well made, with very dark, smooth skins, and features expressing great intelligence and animation. They have none of the characteristics of the negro race, whom they despise.

SOCIETY OF ARTS.—Feb. 19.—'On Submarine Telegraphy' (Cantor Lecture), by Mr. Fleeming Jenkin.—Feb. 21.—Prof. Huxley in the chair.—The paper read was, 'On Modern Legislation in regard to the Construction and Equipment of Steam Ships,' by Mr. T. Gray.

ROYAL INSTITUTION.—Jan. 26.—Sir H. Holland, Bart. President, in the chair.—'On the Sources of the Nile,' by Mr. S. W. Baker.

SOCIETY OF ARTS.—Feb. 5.—'On Submarine Telegraphy' (Cantor Lecture), by Mr. Fleeming Jenkin. Feb. 7.—J. Hawkshaw, Esq., in the chair.—The adjourned discussion on Mr. W. Hawes's paper, 'On the Proposal that the Railways should be purchased by the Government,' occupied the entire evening.

Medical News.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise:—

Lloyd, Thomas Franklin, Finsbury-circus.
Owens, Edward Matthew, Sutton, Surrey,
Smith, Christopher, Paris.
Smith, Walter, Bognor, Sussex.
Tarlton, John Haigh, Birmingham.
Wylie, Robert, Robin Hood's Bay, near Whitby.
Laslett, Alfred Kent, Canterbury.
Body, Henry, M., Cheriton-Fitzpaine, Devon.
Dalley, Charles Thomas, Leicester.
Fennings, Allen, St. Ann's-road, Notting-hill.
Rogers, George Arthur, Queen-square.
Smith, William, Gorton, near Manchester.
Verity, Abraham Robert, Bridgend, Glamorganshire.

The following gentlemen passed their first examination on the 1st inst. :—

Adams, George E. D'Arcy, King's College.
Wilkins, John Canning, University College.

DR. DEMPSTER, Inspector-General of Hospitals, has been granted the good service pension of £100 a year for his meritorious services.

MEDICAL MAYOR.—William Peter Nichols, Esq., senior surgeon of the Norfolk and Norwich Hospital, has been elected Mayor of Norwich.

CAMBRIDGE, MARCH 1.—Dr. Humphrey was this day elected Professor of Anatomy in the room of the Rev. Dr. Clarke, who has resigned. Mr. Alfred Newton, M.A., of Magdalen College, has been elected Professor of Zoology and Comparative Anatomy. Dr. Drosier received the support of a considerable minority of the electors, the votes being for Mr. Newton 110, and Dr. Drosier 82.

The Minister of Agriculture has sent M. Delpech, professor of médecine, M. Raynal, veterinarian, and M. Alfort, to Germany, to examine and report upon the trichina disease prevalent in pork.

FATAL MISTAKE.—An inquest was lately held on the body of Mrs. Anne Woodham, whose death was occasioned by a large dose of laudanum administered to her by her attendant in mistake for tincture of rhubarb.

THOMAS JAMES WOODHOUSE, M.D., London, F.R.C.S., has been appointed Physician to the Royal Hospital for Incurables, West-hill, Wandsworth.

The memorial stone of a new dispensary at Callian has been laid by the Governor of Bombay. The cost of the building, about 60,000 rupees (£6,000), will be defrayed by Mr. Munguldass Nathabhoy, an influential and wealthy Hindoo, resident in Bombay. The dispensary is to be endowed by the same charitable gentleman.

BENJAMIN GUY BABINGTON, M.D., F.R.S., has been appointed Consulting Physician to the Hospital for Diseases of the Throat, 32, Golden-square, London, W.

The *Portage (Wisconsin) Register* announces the death of Joseph Crele, supposed to have been the oldest man in the world. His baptism is stated to be on the register of the Roman Catholic Church of Detroit for the year 1725, so that he was in his 141st year. He died in Caledonia, about four miles from Portage. His great age had for some time made him notorious.

The Central Hall for Art and Science which the late Prince Consort projected is likely to be begun. The site will be to the north of the Horticultural Gardens, and the cost will be £200,000.

THE POLYTECHNIC INSTITUTION.—At the general meeting of the shareholders held at the Institution, Professor Pepper stated the laboratory had been further utilized by the delivery of regular courses of lectures on electricity, geology, and chemistry.

The Metropolitan Board of Works lately held a meeting to consider how they were to discharge that portion of their duties which the Cattle Diseases Bill cast upon them. On the suggestion of the chairman, it was agreed that Committees of the Board should be appointed, one for each metropolitan borough, who would superintend the carrying out of the provisions of the Act within their respective departments.

THE SURREY COUNTY HOSPITAL.—Her Majesty has been graciously pleased to present a bust of the late Prince Consort to this Hospital. The bust, which is of life size, and of the purest Sicilian marble used for statuary purposes, is two feet six inches in height, and is mounted on an elegant coloured marble pedestal four feet high, making the total height six feet six inches.

TESTIMONIAL TO DR. LOBB.—A valuable Testimonial, consisting of a silver salver, and a tea and coffee service, accompanied by a handsomely illuminated volume, containing the names of the subscribers, was presented at the Albion Tavern, on the 3rd instant, to Dr. Lobb, of Aldersgate-street, by several of his friends and patients, on his retirement from practice, in which he had been actively engaged for upwards of 40 years. After the presentation Dr. Lobb was entertained at dinner—Dr. C. Brodie Sewell, the Treasurer of the Testimonial Fund, presiding.

HEALTHY HOMES FOR THE ARTISAN.—At the proposed Exposition Universelle at Paris in 1867, a section will be

devoted to model habitations, combining the cheapness of construction with sanitary arrangements calculated to ensure the highest degree of health and comfort. The Emperor will exhibit in this section houses constructed on the plan of those he has had erected.

NEW CITY LUNATIC ASYLUM.—Last week the Lord Mayor and the members of the Court of Common Council, with the principal officers of the Corporation, paid a visit to the new lunatic asylum for the city of London, which has been erected at the cost of the Corporation at Stone, near Dartford, and is now ready for the reception of patients. They were accompanied by the chairman and deputy chairman, with six of the guardians of each of the three Poor-law Unions in the city, and travelled by a special train on the London and South-Eastern Railway. The asylum has been erected at a cost of about £65,000, from designs by Mr. Bunning, the late city architect, and is intended to accommodate 250 patient. It is pleasantly situated on an elevated piece of ground about a mile and a half from Dartford, overlooking the Thames, and commanding a view of the surrounding country for miles. It is fitted up with baths and lavatories, laundries and workshops, and surrounded by spacious grounds tastefully laid out. Bagatelle boards and other games and means of recreation are provided for the inmates; and, in short, all the appliances for comfort and convenience which have been adopted of late years in the best regulated establishments for the treatment of persons afflicted with insanity in all its varied forms. In the first instance the plans and designs, after certain alterations had been made, were approved by the Home Secretary and the Commissioners in Lunacy, and while the building has been in progress the Commissioners have paid repeated visits to it, and seen that the conditions required by them were being fulfilled. The asylum has been erected under the superintendence of a special committee of the Court of Common Council, of which Mr. Alderman Dakin is chairman, and nearly five years have been spent in its construction.

MR. LAWRENCE ON THE COURT OF EXAMINERS OF THE COLLEGE OF SURGEONS OF ENGLAND.—Mr. Lawrence, in 1826, speaking of the Court of Examiners, says that "admission into this body, with subsequent promotion, depends on seniority; and as the appointment is for life, it must often happen, as it frequently has, that the duties of that court, which if properly performed would require men in the active period of life and the full vigour of their faculties, have been executed by persons nearly approaching or actually arrived at the extreme verge of existence. In an imperfect and progressive science like surgery, such individuals must be far behind the actual state of knowledge; consequently unable to estimate the acquirements of those recently educated, and not the best qualified to represent the surgical profession. Hence we cannot be surprised that, although the Council and Court of Examiners have always numbered amongst their members individuals of justly-earned and acknowledged eminence, their acts as public bodies have not commanded the respect of the profession at large." Mr. Lawrence, now in the year 1866, and himself at the age of 83, is still a member of the Court of Examiners of the College, being the only life-member on the Court.

FEVER IN WHITECHAPEL.—The Medical Officer of Health for Whitechapel, Mr. Liddle, has made a report to the local Board of Works, in which he states that during the past year the number of deaths in the district from fever has been 167, exclusive of those which occurred in the Fever Hospital of those belonging to the district. During the past year the medical officers of the union attended 573 cases of fever, and in the preceding year 395 cases. In the work-house during the past year there have been 535 cases of fever. These facts, Mr. Liddle remarks, indicate that our sanitary arrangements are very imperfect, and that much greater exertion must be made, and further scientific inquiries must be instituted, if this plague is to be checked.

SCURVY.—Last week an inquiry was held by Mr. Humphreys, coroner, relative to the death of one of the crew of the *St. Andrew's Castle*, a ship now lying in the St. Katharine's Dock. The ship *St. Andrew's Castle*, of Glasgow, left Shanghai for London on the 22d of October last. She had a crew of thirteen men, and a lady with two children, the eldest five years and the youngest then only three months old, on board. The lady had no servant, and

was unaccompanied by any other passenger. On the voyage seven of the crew were disabled by scurvy. The deceased man was seized with the same dreadful disease. He had been attacked with intermittent fever and dysentery in China, and he was consequently very feeble; however, the captain treated him out of the "medicine book," and he lived till the ship was being towed up to the St. Katharine's Dock on Friday last. The disability of so large a proportion of the crew from scurvy was, of course, a serious embarrassment to the captain, but his misfortunes had not yet reached a climax. A fortnight before sighting land the lady passenger went mad. The unlucky captain and his mate had thus thrown on their hands, not only the task of minding the unfortunate passenger but the more difficult task of nursing the infant of six months, and of looking after the child of five years of age. Witnesses were called to prove that everything possible was done for the man, and the coroner having summed up, the jury returned a verdict "That the deceased died on board the *St. Andrew's Castle* from exhaustion, scurvy, and dysentery; and the jury wish to express their opinion that the captain of that vessel did his duty well, and with great humanity."

SCIENTIFIC REPORT ON THE TRICHINA.—The Prussian Government had entrusted investigations on the nature and mode of propagation of the trichina to Professor Kühne, of Halle, and zealously were they pursued from 1863 to 1865. The report has been sent in, and states, among other things, the following particulars:—Pigs affected with trichina do not present symptoms sufficiently obvious to be recognised by breeders. It was therefore incumbent on the reporter to elucidate facts connected with diagnosis. Animals were for that purpose fed with meat full of trichina, and daily watched by veterinarians. The latter could hardly detect any change in the health of the animals, nor did slight indispositions present anything which could be construed into a pathognomonic symptom of the disease, yet it was proved by post-mortem examination that trichina had formed in large masses in the muscles of the animals. Hence the breeder cannot be expected to recognize the existence of the malady, nor should he be punished as having sold diseased meat. No difference of race, sex or age, creates a greater or less aptitude to be invaded by the trichina. It is not true, as has been asserted, that trichinian disease is produced by feeding pigs with beetroot, by the ingestion of earthworms, or of moles containing trichina. The investigators have found that the parasites of the beetroot and the moles are not identical with the trichina which infest the pig. Not so, however, with rats and mice, which are sometimes devoured by pigs. Cats also may be thus contaminated: the latter are especially susceptible. It is therefore important to prevent pigs from eating dead animals. It is very likely that foxes and weasels may be very dangerous in this respect, but it is plain that pigs can but seldom feed upon them. Dogs are also very liable to breed trichina, but birds are quite insusceptible. Trichina, which have passed into the stomach of pigs with their food, are therein completely destroyed; hence it may be inferred that the fecal matter of diseased animals is not obnoxious. The culinary precautions to be held in view when cooking pork are the following:—The process of boiling or roasting should be carried on with the greatest care. People should not partake of any meat that has not been sufficiently cooked, and avoid such roast pork the centre of which still presents traces of blood. By salting and smoking ham for about ten days, the trichina are quite destroyed.

VACCINATED COWS IN CONTACT WITH DISEASED CATTLE.—M. H. Bouley stated, February 13th, from his place at the meeting of the Academy of Paris, that all the vaccinated cows which had been sent to England, in order to be placed in contact with diseased cattle, so as to test the amount of immunity acquired by vaccination, had taken the complaint.

ROYAL FREE HOSPITAL, GRAY'S-INN-ROAD.—The thirty-eighth annual general meeting of the governors of this institution was held on the 1st inst. in the board-room of the hospital. The report showed that the year 1865 had been a most prosperous one, the receipts having reached the sum of no less than £1507 7s. 6d. in annual subscriptions; and £3011 2s. in donations, which sums, including £569 7s. 8d., the profit on the anniversary festival last May, presented over by the treasurer, Edward Masterman, Esq., with £6804 14s. 2d. in legacies, made altogether a sum of £11,323 2s.

8d.; thus enabling the committee to clear off all the loans and debts of 1863 and 1864, leaving the hospital in debt only for the balance of the expenditure of 1865. The number of patients admitted during the year was 75,506 out-patients and 1415 in-patients, of whom 414 were cases of severe accident, making a total of 76,921 individuals who received the benefits of this charity in 1865. The expenditure stood—for the year 1865, £6831 4s. 10d.; paid loans incurred in 1863 and 1864, £2538 7s. 3d.; paid old debts of 1864, £1886 16s. 3d.; ditto of 1863, £595 19s. 10d.; making a total of £11,602 8s. 2d.

THE SICK POOR OF LONDON.—The mal-administration of the Poor Law in London, as evidenced by the cases from time to time reported in the press, has induced a number of noblemen and gentlemen to form themselves into a committee for the purpose of concerting measures to improve the condition of perhaps the most dependent, helpless, and ill-used of those under the management of the London guardians—namely, the sick poor. Among those on this committee are Earl Fortescue, the Earl of Airlie, Lord Burghley, Lord Charles Bruce, Mr. Neate, M.P., Mr. H. D. Seymour, M.P., Mr. J. Oliphant, M.P., Mr. Thomas Hughes, M.P., Mr. Charles Dickens, Mr. J. C. Parkinson, Mr. Hans Friswell, the Rev. Dr. Mortimer, the Rev. Mr. Hansard, the Rev. Llewellyn Davis, the Rev. F. D. Maurice, the Rev. S. Martin, Dr. Anstie, Dr. Carr, Dr. C. B. Radcliffe, Dr. J. Rogers, Dr. J. Stallard, Mr. Ernest Hart, Mr. J. Neate, Mr. J. Sharpe, LL.D., Dr. Lankester, Mr. J. S. Storr, Mr. W. H. Smith, and many other gentlemen who have paid attention to the condition of the London poor. A meeting was held the other evening, when many of the above gentlemen were present, and letters were received from the Archbishop of York, Lord Lyttelton, Mr. John Abel Smith, and others, promising to attend a public meeting.

A PHYSICIAN CHARGED WITH POISONING HIS PATIENT.—A Greek physician has been taken before the authorities at Guinwrdgina, Salonica, on the charge of having administered poison to a merchant in the shape of pills.

KING'S COLLEGE HOSPITAL.—The annual court of this corporation was held last week. The report stated that the number of patients admitted into the hospital during 1865 was 1900, and the number of out-patients amounted to 35,792; the number of women confined was 168, and the number of midwifery cases attended at their own homes was 133. The total ordinary receipts for the year amounted to £7834 13s. 3d., and the total expenses to £9145 19s. 3d. The amount of outstanding tradesmen's bills up to December last was £3196 8s. 9d., the total liabilities at the end of the year being £5196 1s. 9d. Legacies amounting altogether to £2190 had been bequeathed to the hospital during the year, and the sum of £1837 8s. 4d. had been received, being the share of the residue of his estate bequeathed by the late Lord Bishop of Ely, besides £19 19s. bequeathed by the late Mr. John Wright. The amount of stock standing in the name of the corporation was £5742 10s. 1d., and the balance of the annual income of the Craven Charity was £354 10s. The Board had also received a donation of £504 from an old friend of the hospital who had constituted 16 members of his family life governors. Donations had also been received from several of the city companies. The committee acknowledge the great value of the connexion of the hospital with St. John's House. They, however, expressed their great regret that notwithstanding all their efforts the expenditure of the past year had amounted to more than £9000.

ASPHYXIA IN INFANTS.—On Monday week, Mr. Carter, Coroner for Surrey, held four inquests upon infants who had died of asphyxia from being overlaid by their mothers.

UNQUALIFIED MIDWIVES.—Mr. Humphreys, Middlesex coroner, lately held an inquest on the body of a poor woman, who had lost her life through the carelessness and incompetence of two midwives. The evidence showed that the women had engaged to attend the deceased in her confinement for 6s.; that they regularly practised as midwives, but had gone through no course of instruction or preparation for the office. They left the deceased in the midst of her trouble, though she called out to them pitifully that "she

knew she was going to die." Finding the deceased was getting low, one of them gave her a powder, though she confessed she did not know what was in it. The husband considered both his wife and newborn child had been sacrificed through the neglect of the midwives, and medical evidence showed that with proper skill and attendance both might have lived. The coroner severely commented on the case, and said the stupidity of the midwives had caused the deceased to lose her life. He wished he had the power to send them to the treadmill for their conduct. The jury returned a special verdict, echoing this opinion, and regretting that the law did not allow them to send the women to trial for manslaughter.—*Globe*.

NEW CITY LUNATIC ASYLUM.—A new asylum for the City of London has been erected at Stone, near Dartford. It is fitted up in every way suitable and convenient for patients, of which it is intended to accommodate 250. Its erection cost £65,000.

FEVER IN NEWCASTLE-ON-TYNE.—Typhus fever, which has been fatal in some of the more neglected parts of the east-end of Newcastle-on-Tyne during the winter, seems to be travelling into the more wealthy quarters of that town. Last week Dr. Watson, a highly respectable medical practitioner, was carried off by it, and on Monday Dr. Hawthorn, a gentleman in large practice, fell a victim to the same disease. On Monday, also, Mr. John Benson, a town councillor, and a gentleman taking a very prominent part in the public movements of the town, died of typhus fever, after a very few days' illness.

THE SURREY COUNTY HOSPITAL.—Some months since Her Majesty the Queen graciously informed the committee of the Surrey County Hospital that she had instructed Mr. Theed, the eminent sculptor, to prepare a bust of the late Prince Consort, to be presented by Her Majesty to the hospital. We understand that the bust arrived at the hospital on Tuesday morning, in charge of Mr. Smith, foreman to Mr. Theed, who was instructed to place the statue in the position selected by the committee, in the vestibule or chief entrance hall, directly opposite the door. The bust, which is of life size and of the purest Sicilian marble used for statuary purposes, is 2ft. 6in. in height, and is mounted on an elegant coloured marble pedestal of 4ft. high, which makes the total height 6ft. 6in. The original from which the bust is taken is in Windsor Castle, but it is said that this last production is by far the more successful of the two, and that it is unrivalled as a work of art. On the pedestal is the following inscription:—"This bust of his Royal Highness Prince Albert was graciously presented to the Surrey County Hospital by Her Majesty Queen Victoria, 1866." The bust will not be exposed to public view until the hospital is opened for the reception of patients. Mr. Theed has at the same time kindly presented to the hospital a tinted plaster cast of his "Good Samaritan," which is considered by competent judges to be one of the finest pieces of sculpture of the day. The original of this work was executed for Mr. Cresswell, of Huddersfield, as a monument to his sister's memory. The cast, which is about 2ft. 6in. by 2ft., is mounted on a pedestal of coloured marble, on which is the following selection from Scripture:—"Inasmuch as ye have done it unto one of these my brethren, ye have done it unto me."—Matthew xxv., 40. This mural piece is placed in a niche near the chief entrance to the hospital, and doubtless it will be an object of interest to every visitor. As the name indicates, it is an illustration of the beautiful parable of the Good Samaritan. Nearly the whole of the foreground is occupied by the prostrate figure of the unfortunate traveller, with the Good Samaritan bending over him, while in the background may be seen the haughty Levite hastening away from the spot.—*West Surrey Times*.

MR. FARNALL, C.B., made an official inspection of Paddington Workhouse on Tuesday week. He was satisfied with all the arrangements. One good feature of the Paddington management is that it has paid-nurses, and only makes use of the best of its paupers to act under these nurses. This is found to be more economical than employing all pauper nurses, as some parishes insist on doing—Greenwich, for instance, where the cost for extras alone for the pauper nurses amounts to upwards of £315 a year.

SCARLATINA and diphtheria are prevalent just now in the suburbs of Edinburgh, and several deaths have occurred during the last fortnight.

ENGLISH WORKHOUSE INFIRMARIES.

THE Association for the Improvement of the Infirmaries of Workhouses held a public meeting at Willis's rooms—the Earl of CARNARVON in the chair. There was a very full attendance of noblemen, members of Parliament, gentlemen of the medical and clerical professions, guardians of the poor, and the general public.

The Archbishop of YORK proposed the first resolution:—“That the present management of the sick in the metropolitan workhouse infirmaries is highly unsatisfactory; that the buildings are inadequate and unhealthy, the medical attendance insufficient, the nursing merely nominal, and the general system of administration radically defective.

Mr. T. HUGHES, M.P., seconded the resolution, and expressed his hearty concurrence in all that had been said by his Grace the Archbishop of York. A grievous and cruel wrong had been suffered to grow up among them, and he rejoiced at meeting so many who, like himself, were resolved to put an end to it.

Mr. G. BROOKE, one of the Guardians of the City of London Union, supported the views of the Association, and wished that the whole Poor-law system might be revolutionised.

The resolution was then carried.

Mr. ERNEST HART moved—“That, with a view to the humane and efficient treatment of the sick paupers, it is desirable to consolidate the infirmaries of the metropolitan workhouses, to support them by a general metropolitan rate, and to place them under uniform management in connexion with the Poor-law Board.” He mentioned several cases showing the inefficient management of workhouse infirmaries, and said the best way of meeting the difficulty was by establishing six district hospitals, each capable of accommodating 1000 patients, to be supported by a general rate, and that the guardians of each district should nominate among themselves two representatives to constitute the government of the hospital, and a certain number of paid inspectors should be nominated by the Poor-law Board to assist the governing body in their deliberations.

Mr. W. H. SMITH seconded the resolution, and stated that apart from all higher considerations of humanity and Christian duty, it was incumbent upon the meeting, on the mere ground of economy, to give every support to a movement so well calculated to promote the comfort and happiness of the poor.

Mr. DAVENPORT BROMLEY, M.P., then moved:—“That, in order to give effect to the foregoing resolutions, it is necessary that immediate steps should be taken to introduce a fitting measure in the House of Commons, and that a deputation be appointed to wait on the President of the Poor-law Board to ascertain whether he will be willing to bring in a Bill for the purpose.” And, “That, in the event of the President of the Poor-law Board declining to take charge of this question, the committee of this association is requested to take independent means to bring forward an appropriate measure in Parliament during the present session.”

Sir J. KAY SHUTTLEWORTH seconded the resolution, and said he had much experience from his former official connexion with the administration of the Poor-law in the city of London, and his conviction was that the guardians were not wholly responsible for the evils which existed.

The resolution was agreed to, and a vote of thanks to the chairman brought the proceedings to a close.

HYPOSULPHITE OF SODA IN CATTLE PLAGUE.—Mr. J. T. Noakes, of Brockley Hall, Lewisham, states that his herdsman has successfully used hyposulphite of soda as a preventive of cattle disease. He recommends that a solution of the strength of five pounds dissolved in 100 gallons of water be given as an ordinary drink to cattle. Those of his herd thus treated escaped the infection, although not isolated. The remainder died.

THE MORTALITY AT HONGKONG.

We have received the following information from a source which we can trust as to the recent mortality in the garrison at Hongkong:—The strength of the 9th Regiment on its arrival at Hongkong in February, 1865, was 839 non-commissioned officers and men, 47 women, and 77 children. Of these 48 non-commissioned officers and men, 6 women, and 28 children have died; 139 non-commissioned officers and men, 27 women, and 31 children have been sent home sick, with several orderlies in attendance on them. There remained at the station in January, 1866, only 636 non-commissioned officers and men, 14 women, and 18 children. The 9th also lost two officers, and one was invalided. On the 31st of May, 1865, the Tamar brought from the Cape 25 officers, 702 non-commissioned officers and men of the 11th, with 54 women and 92 children. On their arrival at Hongkong there was actually no accommodation ready for them. Two companies had to be lodged on board the condemned three-decker *Hereules*, and a few on board the *Princess Charlotte* hulk. The rest were put into sheds at a swampy place called Kawloon, on the mainland, just opposite Hongkong. Disease and death soon began to appear in their midst. Between the 5th of June and the end of last year two officers, 58 non-commissioned officers, five women, and 27 children died. Four officers, 189 non-commissioned officers and men, 22 women, and 35 children have been invalided. There are still in hospital 53 non-commissioned officers and men. Besides this, the 11th has lost all its surgeons; one has died, one is sick, and one is on leave at home. The excuse given by the authorities at Hongkong for not having made proper preparations for the reception of the 11th is that they did not expect them till two months later. They were warned, however, by the Horse Guards long before that the Tamar had been sent to convey the regiment from the Cape to Hongkong. In any case there are plenty of buildings to let which might have been hired for the occasion, or a ship might have been got to take the men out to sea. General Guy was absent in Japan, and Captain Roberts, the Quartermaster-General, would do nothing without his sanction. Two companies were put into wretched “go-downs,” where rice had been stored—places little better than kennels, but the men were more healthy there than at Kawloon. Two companies which were sent to Japan lost only four men, who were, in fact, diseased before they embarked. The causes of this sad mortality are not far to seek. Proper accommodation should have been ready for the 11th Regiment on its arrival. If the General chose to go to Japan he ought to have left proper instructions with the Quartermaster-General, and not have trusted to giving orders through a post which takes twenty days each way. Another undoubted error was the withdrawal of the native Indian regiment and the substitution of unacclimatized European soldiers. Even if men had been brought from India they would not have suffered so much; but those from the Cape were exposed to all the worst effects of the new climate to which they were transported. The excessive nightwork tells very severely on the European troops, who, in addition to other hardships, are deprived of their fair share of sleep. The object of removing the Indian regiment is well known. It was in order that the pay of the rest of the forces in Hongkong, which, while an Indian regiment was there, was maintained at the Indian scale, might be reduced to the colonial standard. But, putting humanity out of the question, the arrangement has proved, in a pecuniary point of view, a very costly one. The heavy expense of sending home sick troops has more than outbalanced any saving which has otherwise been effected; and the loss of so many good soldiers must also be taken into account. Altogether, it is calculated that the shortsighted economy of the authorities has entailed a loss of at least £30,000. The excessive work thrown on the diminished numbers of the garrison will doubtless add to the sickness and mortality. There are still, we understand, in the 11th Regiment, exclusive of one to only 36 non-commissioned officers, 103 privates, and 12 drummers fit for duty.—*Pall-mall Gazette*.

At the meeting of the Academy of Paris, on the 11th of February, M. Auzias-Turenne read a paper, in which he advocated the regeneration of vaccine by inoculating horses. Arm-to-arm vaccination should, however, be continued as before among children.

THE COUNTY INFIRMARIES (IRELAND) BILL.

MR. POLLARD URQUHART'S Bill is set down for a second reading on the 14th inst. It is, however, improbable that it will come before the House on that day, as the attention of the House will probably be engrossed by the Reform debate and by other questions of more general importance. We printed Mr. Urquhart's Bill in full in our number for February 21st. It is the same as was brought in last year, and withdrawn on account of the great press of public business at the termination of the Session. The principal clause in the measure is that which provides that Grand Juries shall present at all future Sessions a specific sum for the maintenance of the County Infirmaries of Ireland, a proviso which has been rendered necessary by the attempts made to withdraw public support from these most valuable institutions and to merge them in the Union Workhouses. This movement manifested itself in only a couple of the counties of Ireland, and it was received with so little favour by the great majority of the grand jurors, who had the best reason to appreciate the value and efficiency of the infirmaries, that it has since died out. The attempt to withdraw these County Grants would never have been heard of at all but for the very needless enactment of Sir Robert Peel's Poor Relief Bill a few years since. It seems to have been a pet project of the Right Hon. Baronet when he held office as Chief Secretary for Ireland, and he hoped to carry the abolition of the Infirmaries by admitting to Workhouses the class of persons from whom the Infirmary patients came. These were defined by the Act as "poor persons," and included the Constabulary, who did not legally come within the operation of the Irish Poor-law. Our analysis of the last report of the Poor-law Commissioners showed that the expectations of the Right Hon. Baronet had proved completely delusive, and that an absolutely insignificant number of the patients had availed themselves of its provisions. The County Infirmaries are now liable at any time to the attacks of a parsimonious juror, and Mr. Urquhart has our best wishes in his effort to obtain legislative protection for them.

THE LATE DR. WEBER.

DR. WYBER was the son of a Glasgow citizen, and was educated at the High School and University of Glasgow. After a few months spent in two voyages to America, and in a short tour on the Continent of Europe, he was strongly attracted by the desire of hospital work in London, and most earnestly endeavoured to obtain an appointment in the London Fever Hospital; and after a short delay, Dr. Wyber was appointed to the office he so much desired, and in performing the duties of which he met his premature death. Up to the very last moment of health, his letters bore the same cheerful happy tone of cordial satisfaction with his work and his new friends that had been his habitual characteristic at home. Dr. Wyber died at the age of twenty-six years, leaving a gap in the affections of his many friends in Glasgow that cannot easily be filled up. He was buried in St. Mungo's churchyard, and was attended to the grave by several of his teachers, and a numerous array of students, who had come to appreciate his worth both as a fellow-student and as, in his turn, one of their instructors. The *Lancet* states, that of upwards of thirty medical officers who have been engaged in the dangerous service of the London Fever Hospital during the last thirty-four years, Dr. Wyber is the first who has died of typhus fever. He has fallen a victim to his earnest devotion to the public service, and to his zeal for the practice of a noble and generous profession. His death is another instance of the risk at which medical skill and experience are obtained.

REPRINTS OF CONTRIBUTIONS.

CONTRIBUTORS to "THE MEDICAL PRESS AND CIRCULAR" are informed that their communications can be reprinted in book form at a very moderate cost immediately after they have appeared in the Journal. It being assumed that the contributions have been properly corrected and revised before publication in the Journal, and great delay and no little expense having been incurred in consequence of alterations made subsequently to publication, it is notified no proofs can in future be sent out, or alterations made in the matter, before reprinting. The rates of charges for reprinting will be forwarded on application at the office.

BIRTHS and DEATHS Registered and METEOROLOGY during the Week ending Saturday, March 3, 1866, in the following large Towns:—

Boroughs, &c.	Estimated Population in middle of the Year 1866.	Persons to an Acre. (1866.)	Births registered during the week ending March 3.	Corrected Average Weekly Number.	Deaths.	Temperature of Air (Fahr).		Rain Fall. In Inches.	In Tons per Acre.	
						Highest during the Week.	Lowest during the Week.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29.331 in. The barometric pressure was 29.71 in. on Sunday, and it fell to 29.01 in. on Wednesday.

The general direction of the wind was N.E. & S.W.
 * The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the 10 years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in workhouses situated outside the municipal boundaries.

§ The mean temperature at Greenwich during the same week was 32.6 deg.

NEW WORKS IN MEDICINE AND SCIENCE.

(From the Publishers' Circular.)

- Bennett (John Hughes)—The Restorative Treatment of Pneumonia 3rd edit. Svo. (Edinburgh, Black) pp. 110, cloth, 4s. (Longmans.)

ADVANCED PAYMENTS.

SUBSCRIBERS are reminded that their subscriptions in all cases must be paid within two months of the date of the order to secure the advantage of the lower rate of £1 1s. 8d. per annum, and that any subscription delayed beyond that period will be charged on the credit scale of £1 2s. 6d. per annum.

Contributors are requested in all cases to forward their communications direct addressed to the Editor of the special department of the Journal in which they reside. Considerable delays have arisen in consequence of matter from England being forwarded to the Editor of the Irish or Scotch Departments, it being necessary to reforward them to London, for revision before publication.

NOTICES TO CORRESPONDENTS.

The Obstetrical Society of London.—The card has been received. M. M.—The subject shall receive attention. *Juvenis.*—The case is published in the last volume of the society's transactions. J. S. Stafford.—We have not yet received the communication referred to. Dr. T.—The *suggestio falsi* was pointed out in our columns long before the subject was noticed by our contemporary. *An Approaching Voice.*—We feel grateful for the kind expression used by our correspondent.

Dr. Eben. Watson's Reply to Dr. Morell Mackenzie is not of sufficient scientific interest to justify its insertion as a leading article. We think the controversy has gone far enough, but will in justice to Dr. Watson insert a short letter of reply to any observations of Dr. Mackenzie's which he considers may require it.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having accidentally "dropped" on a rather quaint puff in the "pill" interest within Saint Saviour's Church here, I copied it *ver. de lib.*, and enclose copy for the "contemplation" of the curious in such matters.—Faithfully yours, BARTLE O'BARRY. London, February 12, 1866.

On a couch, and in a semi-reclining position, with right hand under chin and left hand holding a book, there is a full-sized carved figure of a man, with very large mouth and "ferocious" wig. Carved on front of the couch I read, "*Deceast* April ye 26th Anno Do 1672 aged 72." Then, on a tablet posterior to the figure, I read as follows:—

"Here Lockyer lies intere'd enough his name
Speaks one hath few Competitors in fame
A name Soe great Soe Generall may Soerne
Inscriptions weh doe Vulgar tombis adorn
A diminution 'tis to write in Verse
His Biologies weh most mens mouths release
His Virtues & his Pills are Soe well known
That Envy can't confine them Under Stone
But they'll survive his dust and not expire
Till all things Else at th' Unversall fire
This Verse is lost his Pill embalms him Safe
To future times without an Epitaph."
"Restored October 1711."

LIST OF PAPERS (NOT) READ AT THE MEETING OF THE BRITISH MUTUAL ADMIRATION SOCIETY.

1. On the Vegetable formation of the Baldwin Islands, as suggesting a new theory of capillary attraction, by Dr. Wigsby and Mr. Beardmore.
2. On the theory and practice of ovisuction, based on the minute anatomy of the *chabaza* under high powers of the microscope; being a lecture specially dedicated to the grandmothers of England, by Dr. Bleareye, F.R.S.
3. On shirt-collars as an archetypal relie of the exoskeleton and on the gills of the tuniata, by Dr. Shelly.
4. On the composition of the milk among the Asiatic nomads as explaining the formation of cream of tartar by their revolutions on the Steppes, by Professor Darinann, of Pumpernickel.
5. Professor Wrigley on the veruiform process.
6. On the strata of native hippuric acid recently discovered at Bayswater, under the auspices of the Geological Society.
7. On the successful treatment of homicidal mania by the external application of the *Cannabis sativa*, by Dr. John Bull.
8. On nidification in the *Equus caballus*, by G. P. R. M. D.
9. On the paralysis producible in birds by the application of chloride of sodium to the feathers covering the posterior termination of the vertebral column, by Dr. Handy Fowler.
10. On the arrest of tubes in the horse by a general granulous discharge, by Professor Andreus Hercules, of the N. V. C.
11. On a new species of mouse, the *Mus venulosus* (or farm-'ouse'), discovered in the country round London, by Tittlebat Titmouse, Esq.

BOOKS RECEIVED.

Clinical Surgery: on Diseases of the Testicle, Vesico and Recto-Vaginal Fistula, and Ruptured Perineum. By Thomas Bryant. Part VI. Churchill and Sons.

Photographs (Coloured from Life) of the Diseases of the Skin. By Alex. Balzanno Squire, M.B. Lond. Churchill and Sons.

ERRATUM.

In Dr. Greenway's paper on "Cholera and Choleraic Diarrhoea," page 193, 2nd column, line 44, for "curly stage" read "advanced stage."

APPOINTMENTS.

BAILEY, Mr. I., has been elected Dispenser to the Radcliffe Infirmary, Oxford.
BRADLEY, JOHN, M.R.C.S. Eng., has been appointed House-Surgeon to the Northern Hospital, Liverpool.
FARRELL, WILLIAM K., L.R.C.P. Edin., has been elected House-Surgeon to the Belfast Union Infirmary.
HICKS, Dr. J. BRAXTON, F.R.S., has been elected Honorary Fellow of the Berlin Obstetrical Society.
NICHOLS, WILLIAM P., F.R.C.S. Eng., has been elected Mayor of Norwich.
PEIRCE, W., M.D., has been appointed Second Assistant Medical Officer to the Dorset County Lunatic Asylum, Dorchester.
SMITH, ALBERT R., M.D. Edin., has been elected one of the Physicians to the General Infirmary, Hereford.
SPEARING, ANDREW, M.D. Glasg., has been elected Medical Officer to the Antrium Union Workhouse.

POOR-LAW VACANCIES—RESIGNATIONS.

Bradford (Yorkshire) Union.—Horton East District. Remuneration by case.
Bridley Union.—Third District; area, 4248; population 2400. Remuneration by case.
Hastings Union.—Third District; area, 8144; population, 1552; salary, £40 per annum.
Louth Union.—Grimoldby District; area, 17,217; population, 2854; salary, £40 per annum.
Poplar Union.—Western District; population, 26,108; salary, £75 per annum.
Wem Union.—Wem District; area, 12,196; population, 3526; salary, £70 per annum, including the workhouse.

Medical Diary of the Week.

WEDNESDAY, MARCH 14.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Prof. Huxley, "On the Classification and Structure of the Mammalia."
MICROSCOPICAL SOCIETY.—8 p.m. Papers by Dr. Maddox, Mr. Tuffen West, Dr. Greville, and others.

THURSDAY, MARCH 15.

ROYAL INSTITUTION.—3 p.m. Professor Frankland, "On the Non-Metallic Elements."
HARVEIAN SOCIETY OF LONDON.—8 p.m. Dr. Meredith, "On the Duality of Venereal Ulcers."

FRIDAY, MARCH 16.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Prof Huxley, "On the Classification and Structure of the Mammalia."
ROYAL INSTITUTION.—8 p.m. Mr. Balfour Stewart, "On the Evidence of the Existence of an Etherial Medium pervading Space."

SATURDAY, MARCH 17.

ROYAL INSTITUTION.—3 p.m. Rev. G. Henslow, "On Structural and Systematic Botany."
METROPOLITAN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—7½ p.m.

Births, Deaths, and Marriages.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

ANNESLEY.—At Devonport, the wife of Francis C. Annesley, M.R.C.S., Deputy Inspector-General of Hospitals, of a son.
BENNE.—At Lymington, Exeter, the wife of A. Benne, L.R.C.P. Edin., of a daughter.
BLADEN.—At Stroud, the wife of Robert Bladen, L.R.C.P. Lond., of a son.
CADDY.—At Watcombe, Torquay, the wife of Dr. Caddy, R.N., H.M.S. *Ganges*, of a son.
CRESSWELL.—At Dowlish, Glamorgan-shire, the wife of Pearson R. Cresswell, M.R.C.S.E., of a daughter.
PUDDICOMBE.—At Silvertown, Devon, the wife of E. M. Puddicombe, M.R.C.S. Eng., of a son.
SANDERS.—At Chiswell, Essex, the wife of Dr. Charles Sanders, of a son.
SARRELL.—At Pera, Constantinople, the wife of Richard Sarrell, M.D., of a son.
SOMERVILLE.—At Gosforth, Whitehaven, the wife of W. Somerville, M.D., of a daughter.
THOMAS.—At St. Clair's Carmarthenshire, the wife of J. L. Thomas, M.R.C.S. Eng., of a son.
HOLMES-ARROW.—On March 3, at Manchester, Frank Holmes, M.R.C.S., to Annie Elizabeth, daughter of the late Henry Arrow, Esq.
WALLER.—AUSTEN.—At Trinity Church, Rathmines, by the Rev. Lotus Shire, Frederick Waller, Esq., to Jane, daughter of Richard Austen, Esq., M.D.
MORTON-LORD.—On November 23, 1865, at St. Mark's Church, Darling Point, Australia, by the Rev. Thomas Kennis, Selby Mars Morton, Esq., M.R.C.S.E., L.S.A., late of Haverstock Hill, London, son of John Morton, Esq., Brighton Park, late Superintendent Surgeon, H.F. U.S.A., to Anne Isabel, youngest daughter of the late James Lord, Esq., Woodhouse Grove, Leeds.

BOYD, HENRY, M.D. Glasg., at Argyle-street, Glasgow, on February 18, aged 54.

TAYLOR, JAMES, M.D. Glasg., at Barnhill, Glasgow, on February 16, aged 22.

HUSBAND.—At 28 Clarence-street, Edinburgh, on the 25th inst., Helen Frances Macneill, wife of William Husband, M.D.

HUSBAND.—At 28, Clarence-street, Edinburgh, on the 26th inst., the infant son of William Husband, M.D.

LECTURES

ON THE
NATURE, CAUSES, AND TREATMENT OF
DYSPEPSIA.

Delivered at the Queen's Hospital, Birmingham,

By BALTHAZAR W. FOSTER, M.D., F.L.S.,

MEMBER OF THE ROYAL COLLEGE OF PHYSICIANS, LONDON; LICENTIATE OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND; PHYSICIAN TO THE QUEEN'S HOSPITAL, AND PROFESSOR OF CLINICAL MEDICINE IN QUEEN'S COLLEGE, AND OF THERAPEUTICS AND MATERIA MEDICA IN SYDENHAM COLLEGE, BIRMINGHAM; PHYSICIAN TO THE GENERAL DISPENSARY, BIRMINGHAM.

LECTURE IV.

GENTLEMEN,—In the investigation of diseased action there can be no more fatal mistake than the supposition that we have to deal with forces other than those which exist in the body in health. The phenomena of the pathological state are merely the manifestation of a disturbed action of physiological laws. In reference to our subject the application of this truth is important. The various errors of the digestive process I would have you consider as modifications only in the phenomena which precede or attend on healthy digestion. Do not suppose that fresh forces meet you in these diseases, but seek rather by a careful analysis of the action of the laws which preside over the function, to discover in what way the abnormal results have been produced.

We have already reviewed many influences, more or less removed from the act of digestion, which may excite the maladies under notice, and it now remains for us to inquire into the pathogenic circumstances connected with the act itself. This part of our task will entail a consideration, necessarily limited, of the many conditions essential to the normal course of the assimilating process. Practical medicine can here, as elsewhere, gain much from a well-directed study of physiology. Her greatest successes have ever been closely connected with the correct interpretation of physiological laws. The more complete our knowledge of a function, the more certain our diagnosis, and generally the more successful our treatment of its maladies. The organs which coöperate in the reduction and absorption of our food, have received much attention at the hands of physiologists, and their elucidation of the phenomena of the process will greatly assist us in our task. We may divide for our purpose digestion into three stages—viz., 1st, oral; 2nd, gastric; and 3rd, intestinal. The actions to which the food is submitted in each of these will disclose to us the manner in which many of the troubles of digestion arise. Throughout the alimentary tract we find the food submitted to two kinds of action—viz., mechanical and chemical. These vary in their development in the different stages of digestion. In the mouth the purely mechanical action is most marked, while the chemical change produced is comparatively slight. In the stomach and intestines the chemical metamorphosis of the food is the special part of the function; the purely physical part is much less marked.

1. In the oral stage of digestion, the process of mastication plays the most prominent part; indeed for long it was supposed that only mechanical changes were produced in the food while in the mouth. We now know that the minute division of the food which is obtained by the masticatory action of the teeth, aided by the free secretion of saliva, is also associated with chemical changes in certain constituents of the alimentary mass. These changes will be

considered hereafter. We have first to notice the trituration of the materials submitted to the action of the teeth. By mastication properly performed the food is thoroughly moistened with the saliva (insalivated), and formed into a bolus apt for deglutition and capable of being easily permeated by the juices of the stomach. Comparative anatomy testifies to the necessity of this operation by the varied means Nature has provided to insure its accomplishment in the animal kingdom. The minute division of matter which the chemist calls to his aid in order to procure sometimes a simple solution, at others chemical change, equally witnesses to the essential character of the process. And the fact that neglect or inability to perform this preparation of our food is one of the most fruitful sources of dyspepsia, is a further proof of the importance of mastication. The free secretion of saliva and the healthy condition of the muscles of mastication and of the teeth, as well as a careful exercise of them, are all necessary to insure the proper division of the food. In the young, the habit of swallowing food not sufficiently masticated, and in the old (and sometimes the middle-aged) the inability from loss of teeth to perform the operation properly, are conditions frequently connected with dyspepsia. Under these circumstances the food enters the stomach without having undergone the full chemical action of the saliva, and also in a state unfavourable to the rapid action of the gastric juice. The thorough breaking-up of the food can only be obtained by the combination of the conditions above mentioned, and, we may further add, that under such conditions we obtain also the chemical change which should take place in the food while in the mouth. The mechanical function of the saliva is less striking, though not less important, than its chemical properties.

By the term saliva you must not understand the secretion of any one gland or of the larger glands alone, but you must include in the term all the fluids secreted in the buccal cavity. This mixed secretion not only facilitates mastication and deglutition, and by rendering soluble many portions of our food, thus administers to the sense of taste, but it also chemically transforms the starchy aliments by changing them, first into dextrine and then into grape-sugar. This converting property of the saliva, which it owes to a peculiar ferment called ptyaline or salivary diastase, acts chiefly on the starchy particles when in the mouth, but the conversion continues also in the stomach under favourable conditions. In order that this change should proceed in the gastric cavity, the azotised portions of the food should engage thoroughly the action of the acid gastric juice, for the saliva alkaline in its reaction works but imperfectly in the presence of an acid. We must remember, also, that the continual arrival of saliva in the stomach, even after the food is ingested, assists in the transforming process. Some authors* have attributed in addition to the saliva a power of acting upon the fatty constituents of our food, but the evidence in favour of this view is scanty at present. From the importance of the changes produced in the buccal fluids we can readily understand that alterations in these secretions may give rise to digestive trouble. We find accordingly that the quantity or the quality of the saliva may be in fault. The quantity of saliva secreted daily has been estimated by Bidder and Schmidt at about three and a half pounds. Harley values it at from one to two pounds. This latter estimate nearly agrees with that of Beclard†, and we may assume that about two pounds of saliva are formed daily, bearing in mind that the quantity may vary within very wide limits according to the character of the food. Dry substances demanding a greater flow, moist a smaller quantity of saliva. When this secretion falls short of the required amount, not only is the process of mastication rendered unusually difficult, but the amylaceous food passes into the stomach chemi-

* Longet "Physiologie." 1861.—Harley. Vide "Carpenter's Principles of Human Physiology." 1864.

† Physiologie, 1856, p. 95. Guipon, op. cit., p. 57.

cally unchanged and there impedes the gastric digestion, and further taxes other secretions to perform the unfinished office of the buccal fluid. Clinical experience supports this view, for we find often in smokers, in the salivation of pregnancy, and in infants, that the excessive loss of saliva renders the first stage of the digestive process imperfect, and that it reacts upon the others. When very little saliva is secreted the acid mucus which lubricates the mucous membrane of the mouth may neutralize the alkalinity of the other secretions of the mouth, and thus impede their chemical action. An excessive flow of saliva also assists in the production of dyspepsia. Under these circumstances the continued action of the saliva on the starchy matters in the stomach passes its ordinary limits, and, unchecked by the relatively less active gastric juice, it ceases not when dextrine and glucose are formed, but, by virtue of its ferment, produces further transformation of these substances into lactic or butyric acids.* In this way frequently arise many of the unpleasant symptoms of acid dyspepsia. From what has already been said, you can easily suppose that the quality of the saliva errs chiefly in respect to its alkaline reaction and its ferment. When the secretion has lost its alkaline reaction, the ptyaline loses its transforming power, and the starchy food passes into the stomach unconverted, and acts as an impediment to gastric digestion. The same condition obtains, when the ferment from any cause is deficient in quantity or altered in quality, or when any acid fluid has checked the changes in the mouth. In all these cases laborious and painful digestion may result. In cases of chronic dyspepsias, there are often found many symptoms referable to faults in the transformation of the starchy constituents of food. In such cases valuable indications can often be obtained by testing the reaction of the saliva. In doing so we should be careful to test the mixed buccal fluid, and to avoid the error of merely placing the test-paper on the mucous membrane, where the mucus normally slightly acid may mislead. Before passing away from the consideration of this part of the subject, I would add that the form of dyspepsia, which, in my opinion, most frequently arises from error in the salivary secretion, is the acid form above mentioned. The importance of the converting power of the diastase of the saliva has, I am inclined to believe with Bernard, been somewhat over-estimated,† and while difficulties of digestion may arise in the way indicated above from a defect in the transforming action, I am convinced that they seldom occur, as compared with errors in the opposite direction, which produce some of the forms of acidity. Any deficiency in the action of the salivary diastase may be always supplemented by increased activity in the pancreatic secretion.

(To be continued.)

NOTICE OF A CASE OF

SUCCESSFUL AMPUTATION OF THE THIGH FOR ELEPHANTIASIS OF THE LEG, IN WHICH ACUPRESSURE WAS EMPLOYED.

By P. K. VARTAN, L.R.C.S.E., Nazareth.

(Read before the Edinburgh Medico-Chirurgical Society)

By Dr. HANDYSIDE.

ON the 4th December, 1865, a Moslem, Mahommed by name, aged 35, a native of Jeddah, near Mecca, applied at the Medical Missionary Dispensary, Nazareth. His complaint was hypertrophy of the right leg, from the toes upwards to above the knee, and this swelling—at one part two feet in circumference—was very painful. It had increased gradually in size and painfulness during a period extending to more than four years.

* Vide Cl. Bernard, "Leçons de Physiologie Experimentale," vol. i., p. 164.

† Vide Bernard, op. cit., p. 167, where we find these words; "En résumé le rôle chimique de la salive, dans la digestion paraît donc être insignifiant, sinon complètement nul."

The poor man informed Mr. Vartan that he had been advised to bathe, as a cure, in the Lake of Tiberias. This he had accordingly done during the preceding fifty days, but had thereby, he said, endured a great increase in his sufferings. He was now in such a pitiable state, and begged with such importunity that his leg might be amputated, that Mr. Vartan could not refuse him the benefit hoped for from the operation.

On the 9th of December, at three o'clock p.m., amputation was performed through the lower third of the thigh, acupressure, as in former instances, being employed to close the main vessels divided. At seven p.m. profuse hæmorrhage of florid blood took place. All the sutures, with the exception of one at each extremity of the wound, were then withdrawn, when it was found that the bleeding had not proceeded from any distinct vessel, but proved to be a general oozing from the entire surface of the wound. This was at once checked by the usual styptics, and the wound was then left open.

On the 11th December, at nine o'clock a.m., being the forty-second hour after the application of acupressure, all the needles were removed and the wound closed. These needles, Mr. Vartan remarks, might have been taken off the vessels sooner perhaps with perfect safety.

Subsequently the wound has gone on satisfactorily, healing, of course, by granulation; for its having been disturbed and left open during nearly thirty-eight hours had disappointed this surgeon's hopes of seeing it healed by the first intention, although he adds that his best hopes in him, he trusts, may not be disappointed, and that his connexion with the Medical Mission there under such favourable circumstances may prove a blessing to him.

DECLINE OF THE RINDERPEST.

THERE really seems to be reason to believe that a solid and tangible decline has occurred in the rinderpest. During the sixteen weeks ending March 3 the whole number of attacks reported to the Veterinary Department of the Privy Council has been as follows:—

Week ending.	Current cases.	Back cases.	Total.
Nov. 13, 1865	2669	676	3345
" 25 "	3610	2941	6551
Dec. 2 "	3828	1908	5731
" 9 "	3556	2129	7485
" 16 "	6054	2133	8187
" 23 "	6256	1951	8207
" 30 "	7693	2263	9956
Jan. 6, 1866	7106	1402	8508
" 13 "	9243	2956	12,299
" 20 "	10,041	2801	12,842
" 27 "	11,745	1893	13,638
Feb. 3 "	9153	2290	11,443
" 10 "	11,590	4305	15,895
" 17 "	13,001	5355	18,356
" 24 "	10,167	1143	11,310
March 3 "	7310	2060	9370

The public has, perhaps, been led to form erroneous conclusions on the subject, as the abstracts published weekly have taken no account of the "back cases"—that is, the cases not reported in sufficient time to be included in the weekly returns, and carried forward in consequence to the next week. At the same time, the totals referring to these back cases are too considerable to be overlooked. It will be seen that the aggregate number of attacks in the week ending March 3 was less than in any previous seven days since January 6, while, comparing the number of attacks in the week ending March 3 with the total for the week ending February 17, we see a decline of nearly 50 per cent. The next two or three weekly returns will be of great importance, as they will show whether the measures recently attempted by the Government have really been attended with the good results which they appear to have produced. Another point of great importance in connexion with this question is that the general proportion of recoveries to attacks at the close of the week ending March 3 was 13.949 per cent., while at the close of the first week of November it was only 5.235 per cent.

CLINICAL LECTURE

ON

DEEP-SEATED ABSCESS OF THE THIGH.

By JOHN K. BARTON, M.D., F.R.C.S.I.

SURGEON TO THE ADELAIDE HOSPITAL, AND LECTURER ON SURGERY IN THE LEDWICH SCHOOL OF MEDICINE.

(Continued from page 244.)

HAVING considered the diagnosis of deep-seated abscess of the thigh, we will now turn to the treatment best suited to such cases. The purulent matter being pent up beneath strong unyielding structures, gives rise to great constitutional disturbance, so that an early opening of the abscess is urgently called for, besides there is the danger of the burrowing of the matter along the vessels, which should be avoided if possible. The surgeon should therefore open the abscess as soon as he is satisfied that such a collection really exists. The question whether this should be done by one free opening or by two, an opening or counter opening, or finally by the drainage tube, will have to some extent be decided by the position of the abscess, and also by its acute or chronic character. But I am inclined to think that the latter mode of opening—viz., by the drainage tube—is applicable to nearly all, and is the best in the great majority of cases. I must now relate the mode of treatment and result in Purdon's case, whose symptoms I have already detailed.

Case 1 (continued).—Three days after his admission a free incision was made into the swelling, three inches above the inner side of the knee-joint, fully three inches in depth, before the matter was reached,* the limb was then carefully supported from the toes up with a bandage, and pads were placed round the seat of the abscess, a poultice over the opening, and the many-tailed bandage over all. He went on as well as possible for two or three days, when he had a shivering, the discharge became scanty and thin, mixed with a shreddy substance, and the lips of the wound were everted and gaping; his pulse rose to 120 per minute, and was weak and compressible; the bandage was removed, a large poultice laid over the lower part of the thigh, and he was ordered wine freely, and decoction of bark with carbonate of ammonia. The patient's condition, however, became no better; there was a copious very fetid discharge from the abscess of a thin pus, with masses of shreddy substance mixed through it; the opening, which had been a clean cut of about two inches in length, had in a few days become an oval deep ulcer, about four inches in diameter, from the bottom of which the pus came freely when pressure was made either in the middle of the thigh or in the popliteal space. A free counter opening was now made in the popliteal space, from which but little matter escaped at the time, but next day the edges of the ulcerated wound looked more healthy, and soon a copious discharge of dead cellular tissue came from both openings, and the constitutional symptoms began to improve. That a considerable quantity of the fascia lata perished and came away was not doubted by those who were present, while the layers of dead tissue were removed from the wound. During this process of separation of dead tissue from the inter-muscular space, pledgets of lint soaked in a weak solution of chloride of lime were inserted deep into the wound twice a day with very good effect. In place of this a solution of citric acid, as it has been recently recommended for such cases, was substituted for a few days to try its effect. We found the fœtor very much controlled by it, and the wound looked better after its use, but certainly the patient seemed to suffer more pain from it than from the use of the other solution. The constitutional treatment consisted of wine, bark with carbonate of ammonia, and afterwards the perchloride of iron, with opium to procure sleep and allay pain. The pain at this time—i.e., when the sloughs were coming away from the interior of the large cavity which the abscess had formed—was intense, the

* Nearly a pint of healthy pus was discharged, no pressure being made upon any part to force it out.

patient, a young man, crying bitterly and declaring it was intolerable. I have no doubt that the internal branch of the popliteal nerve was laid bare. I did not see it, but from the position of the abscess, and from the character of the pain as described by the patient, this appeared certain. As was to be expected, considerable contraction of the hamstring muscles took place, so that the leg was nearly quite flexed on the thigh, the patient being unable to do more than move it to a right angle. Passive motion continued steadily for several weeks succeeded in overcoming this, and he left the hospital with a straight and sound limb.

What occurred in this case appears to have been an erysipelatous inflammation of the cellular membrane in the vicinity of the abscess, with consequent sloughing; this followed almost immediately upon the opening being made for the evacuation of the pus, being ushered in by shivering, and accompanied by great depression of the vital nerves. In all such cases something of this kind is to be apprehended when the abscess is acute, and no distinct sac has been formed as in this case, we see what may occur; and when the abscess is chronic and walled in by a well-marked sac, this sac is likely to become inflamed, and when it does so is accompanied by the most serious constitutional depression. In abscesses where a free incision is sufficient not only to evacuate the pus, but also to afford it a constant and ready discharge afterwards, as quickly as it is formed, this does not occur, nor in cases where the drainage tube being employed the pus is discharged gradually and no air is admitted into the abscess. It appears to me that the cause of this low form of inflammation is not the action of the air upon the interior of the abscess, but the action of the mixture of air with the pus which is retained, we have all the conditions for decomposition—heat, moisture and air. The pus under these conditions readily decomposes, and at once becomes the cause of gangrenous inflammation of the sac of the abscess, or of the cellular tissue in the neighbourhood.

If this view be correct, our treatment should be directed to obtaining such an evacuation of the abscess that its contents could not decompose. This may be accomplished in either of two ways—1st, by laying open the abscess in such a manner that no pus can collect in it, but must run out as it is formed; 2nd, by the use of the drainage tube, so that the pus may be gradually evacuated without the admission of any air into the abscess. In cases where the abscess is small, or where it is so placed that it admits of a free opening or two free openings being made into it, the first plan will succeed, and the patient's relief be immediate, while his recovery will be rapid; but most cases of abscess in the thigh cannot be treated in this manner successfully. In the case just related this was attempted, but without success. After a very free opening was made the sides of the abscess and the whole of the neighbouring part of the limb was carefully supported by pads of cotton wadding, surrounded by the many-tailed bandage, with the view of giving such support as would prevent the collection of pus in the space between the muscles, but it was not until a very free counter opening in the ham was made that this was accomplished. The reason I made a free opening in this case instead of using the tube was that the constitutional symptoms from the retained pus were very severe, and a free opening was sure to relieve them at once. So it did; but from the subsequent progress of the case, I think my patient would have done better had I taken the more cautious plan of inserting a drainage tube.

The following case illustrates its beneficial action:—

Case 3.—James Stafford, a porter, 20 years of age, a strumous-looking young man, was admitted into the Adelaide Hospital upon the 11th of last February on account of a tumour which occupied the upper and anterior part of the left thigh. He had latterly been addicted to drink. About seven weeks previous to his admission, while carrying a heavy load, he gave his left leg a twist, from which he felt considerable pain at the time, but he observed no swelling until a week afterwards,

when he found there was a tumour in the upper part of the left thigh, which has gone on gradually but steadily increasing in size. For the last week he has been confined to bed, being unable to straighten his leg, and suffering excessive pain. Upon examination we found the whole of the upper part of the left thigh very much swollen, the foot and leg being œdematous. A tumour the size of half a cricket ball occupied Scarpa's triangle. It was clearly divided from Poupart's ligament by a distinct space; three or four enlarged and tender glands were to be felt in the groin; the whole limb was œdematous, but still the tumour could be distinctly isolated from the surrounding swelling; an indistinct deep-seated fluctuation could be felt in it; there was no bruit audible, nor any pulsation to be felt; the femoral artery beat strongly above it, and the arteries of the leg could also be distinctly felt pulsating; there was considerable constitutional disturbance; countenance pale and anxious; pulse over 100; scarcely any sleep from the pain. Upon the 15th of February a drainage tube was passed through the tumour; this was accomplished simply by making an opening with a long straight bistoury, through which a probe, having the tube firmly and neatly attached to it, was introduced, this prevented the escape of the contents completely. A similar opening was then made in the opposite side of the tumour, and the probe pushed out at this and quickly drawn through, leaving the tube projecting from both openings. Not more than an ounce of matter escaped until the tube was in, when from both ends it flowed out freely; it was whey-like strumous pus, with flakes of lymph floating in it. No pressure whatever was made in the sac, but a warm poultice was laid over tube and all. Upon the following day (16th) the discharge was slight; the constitutional disturbance much relieved. 17th: He had slept well, but there was no discharge, and there was a red blush over the outside of the thigh; tumour very tender upon the slightest pressure. Next day these signs of inflammation had subsided, and he rapidly regained his appetite, when all tenderness had disappeared; there being a very slight discharge from the abscess, the tube being low in the openings, it was withdrawn; it was in the abscess about a week. Shortly after this the patient left the hospital.

You observe that some inflammation did take place in this case, but it was trivial, and quickly disappeared. The patient was of a strumous habit, and a drinking man besides; yet he escaped all severe inflammation of the sac, and left the hospital in about a fortnight from the time of his admission quite well. While urging upon you the advantages of the drainage tube in such cases, let me caution you against the commission of two mistakes, either of which would be fatal to its success—1st., take care your tube does not slip out—to avoid this you had better always use a long tube, the ends of which will pass out beyond the poultice, the purulent matter being received upon cotton wadding or tow. If you do not attend to this, the end of the tube becomes fixed in the poultice, and when this is taken off it will be pushed out. If you try to replace the tube you will often find it very difficult to do so, and the poking and working to get it into its place again will be the worst thing possible for the interior of the sac, and if you do not replace it the abscess is in a worse state than if you had treated it at first by a free incision, for there could be nothing worse than two little openings sufficient to admit the air, but insufficient for the discharge of the pus. The second caution is, to take care not to remove the tube too soon. If inflammatory symptoms come on, don't imagine your tube is the cause. I have shown you their cause is much more surely when it is not employed. Leave the tube alone until all symptoms of pain and swelling of the part has entirely subsided. When this has taken place you will observe the tube becoming low in the openings; you may then withdraw it with safety.

MR. BAKER BROWN has just been elected a member of the Medical Society of Christiania, in recognition of his services in operative surgery.

Proceedings of Societies.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, FEBRUARY 7TH, 1866.

Dr. BARNES, President.

THE following gentlemen were elected Fellows:—Messrs. J. C. Burrows, Brighton; Robert Jones, Manchester; J. J. Phillips, Guy's Hospital; Samuel Tilley, Rotherhithe.

THE PRESIDENT announced that several important responses had been received in answer to the invitation to aid the approaching exhibition of instruments. Dr. Radford of Manchester had forwarded a very large and valuable collection. Dr. Hugenberger of St. Petersburg, promised contributions from St. Petersburg and Moscow; Prof. Ninon, from Denmark; Drs. Laggati and Casati, from Italy; and Dr. E. A. Meissner, secretary of the Obstetrical Society of Leipzig, offered the cordial aid of that Society.

Dr. MEADOWS related two cases of

AMPUTATION OF THE CERVIX UTERI.

In both the operation was performed for *allongement* of the uterus, with more or less complete procidentia. In one case the patient was 23 years of age, single, and had suffered from procidentia three years. Treatment of various kinds, by pessaries and otherwise, had been tried without any benefit. The uterus measured four inches and three-quarters in length, the length of the cervical cavity being fully two inches and a half. The *allongement* was limited to the infra-vaginal portion of the cervix. There was no rectocele or cystocele. About an inch and a half was removed by means of the *écraseur*, the patient making an excellent recovery. In the second case the patient was 28 years of age, married, and had had two children and two abortions. She first suffered from procidentia after the birth of the second child, and for several years the uterus has been outside the vulva. On examination, it was found to measure no less than five inches and a half, the uterus being also much thickened and indurated. There was neither rectocele nor cystocele. About two inches of the cervix was amputated with the *écraseur*, but so difficult was it to cut through the thick indurated cervix that no less than two wire ropes and three chains were broken before the operation was accomplished. The uterine wall at the seat of amputation measured fully an inch in thickness. The patient has since made an excellent recovery, and in both these cases the uterus has continued so high up that there is every reason to hope that a cure will be effected.

Dr. BARNES related two cases of

SUDDEN DEATH DURING LABOUR.

In one case, that of a primipara, maniacal excitement came on during the dilatation of the cervix. Chloroform was given to induce moderate anaesthesia, so as to facilitate the application of the forceps. Gentle traction, aided by uterine contraction, effected delivery in half an hour. The placenta was cast. The patient maintained a good pulse; she spoke deliriously at times, but also rationally afterwards. Death occurred almost suddenly ten hours after delivery. No post-mortem examination was held. He (Dr. Barnes) did not think death was owing to the chloroform, but was disposed to attribute it to the nervous shock which was manifested before the chloroform was given. The other case was more clear. The woman was in her seventh labour. Convulsion, stertor, and syncope set in before the expulsion of the child. The child was expelled alive. The mother died in twenty minutes afterwards. A small clot, quite recent, was found in the left thalamus opticus; and another, larger and of a dissecting

character, in the left crus cerebri. The abdominal and pectoral organs were healthy. The record of such cases Dr. Barnes considered to be exceedingly important, as supplying illustrations of the fact that death during labour might occur independently of any fault on the part of the practitioner.

Mr. BENSON BAKER read a paper on

ABORTION AND MENORRHAGIA DEPENDENT UPON
LEAD-POISONING (WITH CASES).

The author observed that this subject had received little attention in this country. In Dr. Graily Hewitt's work "On the Diseases of Women" there was an allusion to it, and reference to a paper in the *Archiv. Gén. de Méd.* This was all the author had been able to learn from the obstetric literature of this country; consequently he had availed himself of M. Paul's paper, of which he had made an abstract. The author's cases and observations afforded concurrent testimony of the effect of lead-poisoning in the woman. The lead poison killed the fetus in utero, and then abortion took place. Not that abortion was dependent upon the action of lead on the muscular structure of the uterus. After abortion took place, persistent menorrhagia was often found to exist, and which would not yield to ordinary treatment, but was cured by treating the patient for lead-poisoning. With respect to the mortal effects on the spermatozoa, the woman being free from lead-taint, cases had not come under his observation, although M. Paul affirms that the mortality to the fetus is equally great whether the father or the mother be permeated with lead poison.

Dr. SANSON read a paper

ON THE ANÆSTHETIC PROPERTIES OF THE BICHLORIDE
OF CARBON.

The author considered that this new anæsthetic would be of great value to the practitioners of obstetrics. Very much as to its constitution and properties had yet to be determined, and more could not be attempted at present than the presenting to the Society a few scattered hints and observations. Dr. Sanson claimed to be the first to describe this body as an anæsthetic in his book on "Chloroform," published in May, 1865. It was then called tetrachloride of carbon; it has since been determined to be a bichloride, and Sir James Simpson has suggested for it the convenient term chlorocarbon. The fluid possesses many of the characteristics of chloroform; its odour, however, is more pleasant and less pungent; its density is slightly greater, and its volatility less. It takes a longer time to induce anæsthesia. On the 4th of July, 1864, the author, in conjunction with Dr. John Harley, tried the effect of the inhalation of the new anæsthetic upon a frog. The circulation in the web of the foot was observed by the microscope throughout the process. It was seen to cause a considerable amount of irregular muscular action, and a very decided contraction of the capillary arteries. A state of torpor was then induced for three-quarters of an hour, but reflex action was not wholly abolished. Experiments were made upon dogs and guinea-pigs. In these there was considerable muscular agitation at the outset. Deep anæsthesia was slowly produced, but, once induced, continued very profound until death. The post-mortem signs were, complete collapse of the lungs and distension of the right side of the heart, so that the organ assumed a globular form. The sensations produced by the inhalation of the bichloride of carbon are at first very agreeable; there is a pleasant sensation of warmth, and, as the author thought, a freedom from the vertigo such as is produced by chloroform. Dr. Sanson has employed it in cases of midwifery. It was readily inhaled; it mitigated the pains, and in one case almost completely abolished them; it did not interfere with consciousness. In reviewing the relative merits of the two anæsthetics, the author considered (1) that chlorocarbon has the advantage over chloroform in its being inhaled with greater

comfort; it is not susceptible of decomposition with the formation of deleterious chlorine compounds; and its cost will probably be considerably less. Being much less volatile than chloroform, it will probably be best administered by pouring it upon a sponge wrung out in hot water. (2) It is, during its early stage of action, a powerful stimulant to the circulatory system. It will probably be especially valuable in midwifery, for it abolishes pain without affecting consciousness, and its tendency is certainly to increase muscular action. (3) It is not advisable to induce deep narcotism by means of this agent. Its profound effects are very persistent, and it is eliminated from the system slowly.

Dr. GREENHALGH stated that two and a half months ago he requested Dr. Sanson to administer chloroform to a lady during the removal of a large polypus from the uterus. She was extremely anæmic and feeble, from large and frequent losses of blood occurring over a period of two years and a half. She had a damaged heart, and a profuse sanious and offensive discharge from the vagina. Shortly after the administration of the chloroform, and before complete anæsthesia was induced, her pulse began to falter, her breathing became embarrassed, and her countenance livid. Dr. Sanson, without delaying the inhalation, substituted ether with the best results. Dr. Greenhalgh begged to ask that gentleman if he had adopted a similar practice in other cases with good effects; and if so, whether he considered that the vapour of ether could be regarded as an antidote to the evil consequences of chloroform, and whether he could offer any physiological explanation of how such beneficial effects are brought about.

Dr. SANSON replied that it was his constant practice to administer ether if in any case chloroform seemed to produce a depressing effect. Indeed usually, in prolonged operations, he thus maintained the anæsthesia. The substitution, or rather addition, was never attended by any return of sensation. He always found that the plan answered admirably: it certainly restored the force of the circulation. It was perhaps premature to explain the rationale of the procedure; but he would remark on the singular circumstance that whereas chloroform tended to empty the blood-corpuscles, ether tended to distend them—chloroform reddened the blood, and ether darkened it. There thus existed, as it were, a natural antagonism amongst agents of the anæsthetic class. Again, they influenced differently the sympathetic system. Ether would cause contraction of the heart and arteries even during the period of the influence of chloroform, and the bichloride of carbon did the same in a marked degree.

Dr. SNOW BECK read a paper

ON ENLARGEMENTS OF THE UTERUS WHICH FOLLOW
ABORTIONS, PREMATURE OR NATURAL CONFINEMENTS;
WITH CASES.

The author remarked that these enlargements had been long recognized by pathological anatomists, and quoted some microscopical observations by himself, and communicated to the Medical Society of London in 1851, which showed that the pathological condition essentially consisted in an enlargement of the muscular tissue of the uterus, without the presence of any inflammatory or heterologous deposits. The causes were considered to depend chiefly upon—(1) a want of complete and persistent contraction of the uterus, which permitted an increased circulation of blood in the gravid organ, and interfered with the changes which took place after parturition; and (2) on the partially developed state of the uterine tissue in abortion, which appeared to be unfavourable to the development of those changes necessary to its complete reduction in size. The enlargement of itself gave rise to few and comparatively slight symptoms, unless it existed to such an extent as to be felt as a tumour in the hypogastrium; but it rendered the patient liable to profuse hæmorrhages, coming on suddenly and without appreciable cause. These en-

largements might exist for many months, or even for some years, without any symptoms of importance; but from the recurrence of the catamenia, or other causes, congestion of the enlarged organ was gradually induced; or congestive inflammation, which may be either of the whole or of any portion of the uterus, might take place, the usual symptoms of uterine affection being then present. Amongst the subsequent changes which took place were anteversion and retroversion, with more or less bending of the organ, which lesions interfered with subsequent impregnation. But a more important change was a gradual hardening of the organ, which reduced it to an indolent state, and rendered it very rebellious to treatment. The modification of the symptoms thus produced was shown by the cases recorded, and the physical examination of the organ detailed. The author found that in these cases the uterus was equally enlarged, smooth, pyriform, the cavity enlarged, and the orifice open. The sound readily passed to an extent varying from three to five or six inches. When inflammation was added the organ became tender, the arteries were felt to beat with more or less force, and the anterior became very sensitive. Subsequent and various alterations were made: the lips became enlarged, often lobulated, projecting into the vagina, red and raw in appearance, and bounded by a distinct line, which marked the division between the mucous membrane of the vagina and that of the uterus. It was this condition of the organ which had been so frequently described as ulceration, although no such morbid change actually existed. With respect to the treatment, various cases were recorded showing the importance of injecting the cavity of the uterus with astringent lotions, and the safety with which it could be done, provided the actions of the uterus were perfectly quiescent. The cavity of the uterus being enlarged, and the orifice open, impregnation readily took place; and the physiological changes which followed were decidedly the best means of restoring the organ to the healthy state. Congestion or inflammation, when present, would have to be met by the usual means; and when the uterus was in the hardened, modified condition, in addition to the ordinary means of treatment, it would require some local stimulant to rouse the local action, and enable the other remedies to act. For this purpose cauterizing the lips with potassa cum calce had been generally employed.

The PRESIDENT observed that he continued the practice of injecting a solution of perchloride of iron into the uterus to arrest hæmorrhage after abortion and labour, and with excellent effect. He no longer dreaded flooding as of old. So far he could illustrate by experience the safety of intra-uterine injections. But he thought a more desirable method of applying fluid styptics or caustics to the inner surface of the uterus would be by swabbing; that is, soaking a bit of sponge or cotton-wool in the liquid, and passing it into the cavity. He had contrived an apparatus for this purpose. An excellent plan of applying solid nitrate of silver was one he had learned from Sir Benjamin Brodie. That eminent surgeon dipped a silver probe in fused nitrate of silver, thus obtaining a thin stratum, which could be passed freely and safely into a sinus. This was the safest way of cauterizing the inner surface of the cervix or body of the uterus.

Dr. GREENHALGH said that Sir J. Y. Simpson had described these enlargements under the terms of subinvolution or incomplete involution of the uterus. He (Dr. Greenhalgh) quite agreed with the author as to their frequency and the obscurity of the local symptoms. He regarded it as a common cause of sterility, but that where impregnation resulted it was always curative, except where abortion ensued. In this disease he had found the uterus enlarged, flabby, and ill-defined, the sound entering an enlarged cavity four inches, and even seven inches and a half. He considered that hæmorrhage was not a frequent symptom in this disease, and, where it did exist, was mainly attributable to some affection of the lining membrane of the uterus. He advised, where hæmorrhage was frequent or profuse, so as to affect the general powers

and resist the ordinary treatment, the injection of the compound tincture of iodine into the uterus; but laid great stress upon the importance of first freely dilating the internal os uteri, which dilatation in itself was more or less curative. He had found resolvent and sedative pessaries of value, as also douches of tepid and cold water with a Kennedy's syringe, and medicated fluids. He likewise advocated the administration of tonics, with the iodide of potassium and liquor of the ergot of rye, and alterative doses of the bichloride of mercury. He relied greatly for success upon improvement of the general health, out of some impairment of which this affection frequently originated and persisted.

Dr. WYNN WILLIAMS agreed with much that had been stated, but, remarking on that portion of the paper alluding to ulceration of the os uteri, he considered there were various degrees of ulceration in mucous membranes as well as in the skin, according to the strength and nature of the irritant. Fortunately the mucous membrane covering the os and cervix uteri is not ordinarily exposed to an irritant powerful enough to produce the amount of ulceration which we so often see in prolapsus uteri. He found that superficial ulceration, or excoriation, happens when perverted or irritating secretions remained in contact with the mucous membrane of the os and cervix uteri. For treatment he relied on constitutional and local remedies, and found nothing answer so well as the injection of weak solutions of iodine. As before stated to the Fellows of the Society, he considered iodine as perhaps the most powerful disinfectant or decomposer of the products of animal decomposition we possess.

Dr. RASCH said he saw a great number of cases of subinvolution of the uterus, in some of which the sound would pass six or seven inches. Careful bi-manual examination left no doubt that there were no tumours in the uterus, the walls being in some cases quite thin and flaccid, like a bladder. He had often practised intra-uterine injections. He had mostly used acet. pyrolignos, recommended by Carl Mayer, though not for this purpose. Diluted with equal parts of water it had often checked obstinate flooding, and not produced untoward symptoms. The patient should stand or walk after the injection, to allow the fluid to gravitate out of the uterus. He thought, before injecting, if any flexion of the uterus existed, it should be known, as this prevented the ready outflow of the fluid. To distinguish between broken and merely reddened mucous membrane on the os uteri, he used, with a brush, a solution of nitrate of silver. The parts denuded of membrane presented an appearance strikingly different from those which were covered.

At the annual meeting on Jan. 3rd, the following by-law was passed:—"That a limited number of medical students, bringing a recommendation from his lecturer in midwifery, be admitted to the ordinary meetings of the Society, without privilege of participating in the discussions." Applications to be made to the honorary secretaries.

SURGICAL SOCIETY OF IRELAND.

MARCH 2ND, 1866.

Professor HARGRAVE in the Chair.

TWO PULMONARY VEINS OPENING INTO THE RIGHT AURICLE—OPEN FORAMEN OVALE.—DR MAYNE'S CASE.

Mr. B. W. RICHARDSON observed that Dr. Macalister having alluded on the last night of meeting to a case which occurred in the practice of the late Dr. Mayne, and of which he (Mr. R.) had from memory informed Mr. Macalister, he thought it better, that there might be no misunderstanding regarding the particulars of the case, to mention its leading features. He (Mr. R.) had since looked at the drawing which he made of the anomaly many years ago, and found that instead of one, two pul-

monary veins opened into the right auricle, and likewise that the foramen ovale was open. The right auricle and ventricle were enormously dilated, and the walls of the latter were extremely thin. The pulmonary artery was of large calibre, the aorta, on the other hand, being much below its normal size. In this case, then, arterialized blood mixed with the blood brought into the right auricle by the two cavæ. This mixed blood partly passed into the right ventricle, thence to the lungs, and partly into the left auricle, where more decarbonized blood was added, and finally passed through the system. The full particulars regarding the case he (Mr. R.) believed are to be found in the Transactions of the Dublin Pathological Society.

EXTENSIVE DISEASE OF THE MITRAL VALVE, WITHOUT THE USUAL MURMUR.

Dr. BENSON said there was a morbid appearance of the heart which, although not very uncommon, he thought it might be interesting to exhibit before it was put into the Museum. A female, 26 years of age, was admitted into the City of Dublin Hospital about ten days ago, labouring under an affection of the heart, and on examining her he found a very feeble impulse indeed, and the sounds of the heart scarcely discernible. The pulse at the wrist was very rapid and irregular, so much so that it could not be counted, and so weak that, taking it in connexion with the feebleness of the heart's action, and a certain degree of lividity of the countenance and some œdema, he was led to the conclusion that it was a softened condition of the heart with which he had to deal. On the most careful examination he could not discover the slightest murmur. After a week in hospital, gastritis set in with great violence, and in her weakened condition this complication proved fatal in two or three days. On making a post-mortem examination he found the following appearances:—In the left ventricle there was an altered condition of the mitral valve. The valve projected in a funnel shape into the cavity of the ventricle, the edges of the curtains uniting, and leaving an opening for the passage of the blood so contracted that the little finger could not be got into it. The edges of this opening were thickened; it presented the appearance which Dr. Bellingham compared to a button-hole, and which Mr. Adams said was like the opening into the rima glottidis. What was particularly remarkable was, that in this instance there was no murmur whatever to be heard during the patient's stay in hospital, and this fact led him into supposing that there was no valvular disease. The heart itself was considerably hypertrophied, but very little softened. There was no possibility of regurgitation taking place from the auricle into the ventricle. There was therefore no murmur accompanying the first sound which so generally occurred in disease of the valve. This was one of those cases that led medical men at first to undervalue the stethoscope and to think it was of no use in diagnosing disease in the valves, because, in some cases, great disorganization of structure was found after death where there had been no murmur. But Mr. O'Ferrall, in the *Dublin Quarterly Journal*, brought forward some facts to show how that this, instead of throwing any doubt on the usefulness of the stethoscope, rather confirmed it. He found that in two or three cases where there was a loud bellows and even a rasping murmur, this was afterwards lost, and on making a post-mortem he found the appearance presented here—viz., the little slit or button-hole opening at the extremity where the edges of the mitral valves meet. He attributed this very properly to the fact that regurgitation took place at first, and then they had the murmur; but as the disease progressed, and the valves closed up more and more, the murmur was totally stopped; and, so far from this showing the uselessness of the stethoscope, it actually confirmed all the observations made by it. Dr. Hope, in his great work on "Diseases of the Heart," marked the distinction between disease of the valves and softening of the heart, by saying that in disease of the valves there will always be a murmur. In softened heart

there was very much the same kind of symptoms; but the differential diagnosis between the two depended on the murmur being heard in the case of valvular disease, whereas there was no murmur in the case of softening of the heart. It is plainly shown by this specimen that such a diagnostic sign cannot be relied on. The first account of this disease was in the first volume of the *Medico-Chirurgical Transactions* by Mr. Abernethy, and then a very valuable paper on the subject by Mr. Adams was published in the *Dublin Hospital Reports*, where he compared this slit-like opening to the opening of the rima glottidis. This disease, as it progresses, appears to change its character. In the early stage of the disease the murmur is found; in the latter period of the disease the murmur may be lost, and a person not acquainted with the circumstances as detailed by Mr. O'Ferrall might suppose this arose from some improvement in the condition of the organ. Mr. O'Ferrall was soon prevented from holding such an idea by finding the symptoms not relieved, and a post-mortem examination fully accounted for the phenomena.

INJURY OF THE SPINE.—FRACTURE OF FIFTH DORSAL VERTEBRA, ETC.

Dr. GEOGHEGAN presented for inspection, the morbid parts taken from the body of a man who had suffered fatal injury of the spine, and who survived about three months.

The subject, a person 38 years of age, and of intemperate habits, was admitted in January last into the City of Dublin Hospital, having sustained, about two months previously, a fall from a height of a few feet into an area, striking upon his head, and somewhat on the left shoulder. The symptoms observed immediately afterwards were those of concussion of the brain, and were quite transitory. On recovering consciousness, the patient found himself completely paralyzed in sensation and motion of both lower limbs, the sensorial functions being now intact. There was complete retention of the urine for the first week; there were neither reflex movements (on tickling, pinching, &c.), nor priapism; the temperature of the limbs was natural.

On his admission (under the care of Dr. Croly, to whom I am indebted for the earlier history), large bed-sores on the sacrum and beneath the left scapula were visible; the lower limbs and the prepuce were œdematous, and the latter inflamed; urine and stools were discharged involuntarily, and the former appeared constantly to dribble away.*

* The condition which is ordinarily designated as "dribbling of urine" (conveying, as it does, the notion of a passive mechanical action) should, I conceive, be abandoned. Close observation of the phenomenon has long since satisfied me that the discharge, like that of the fœces, is not continuous, but in jets, the result of involuntary contractions of the muscular coat of the bladder, repeated at first at short intervals, and is perhaps of a reflex nature. It is quite distinct from the dribbling which results in a bladder distended to its maximum, as in retention, and is due to the same cause which, in certain cases of stricture of the urethra, causes incontinence of urine during sleep. In the observation of several cases of spinal injury with incontinence, and in analogous cases of disease of the vertebræ or cord, I have never found the bladder in a state at all even approaching to distention. In the case now recorded, the involuntary contractions of the organ (should they be viewed as of a truly reflex character) are interesting in respect of the absence of similar movements in the lower limbs. Their properly reflex character under all circumstances is subject to doubt. In fact, the whole question of the reflex character of ordinary micturition, as laid down by physiologists, and more especially since the late interesting and important observations of Budge of Philadelphia, respecting the production of contractions of the bladder by excitation of the crura cerebri, and the existence of voluntary motor filaments supplying the organ through the third and fourth sacral nerves, appears to me, for reasons which I may possibly hereafter assign, to require reconsideration and revision. To any one who will take the trouble to observe his own act of *unforced* urination, it will be clear that the view which includes the diaphragm,

and is reported to have been ammoniacal, and charged with earthy phosphates and "viscid mucus." The anæsthesia was found to extend as high as the middle of the chest. No irregularity of the vertebræ or of their spinous processes was to be discovered.

When placed under my charge I found respiration to be almost completely diaphragmatic, but tranquil. The general aspect was cachectic; the strength pretty good, and the circulation but little depressed. The urine was charged with carbonate of ammonia, and deposited a peculiar microscopic modification of the earthy phosphates, but at that time contained scarcely any pus. When the bladder had been washed out, the urine regained its normal acidity. Notwithstanding assiduous attention, the patient sank, and rather rapidly towards the close. For the last twenty-four or thirty-six hours the urinary secretion was almost completely suppressed, yet without cerebral symptoms. On dissection, a few hours after death, no *rigor mortis* existed in the lower extremities, but was noticed in the upper, though feeble in character. A marked angular curvature was observed opposite the fifth dorsal vertebra, which seemed to have sustained a fracture; the vertical depth of the body of the bone being diminished by fully one-third in front, and considerably throughout its whole antero-posterior diameter. The compact investing layer, where it forms the anterior boundary of the spinal canal, had been disrupted and carried downwards and backwards, thus narrowing the canal and compressing the spinal cord. In the anterior third of the body (as well seen in the vertical section transmitted to the museum) there is a somewhat obscure and irregular line passing downwards and backwards, as if the track of a fracture of considerable standing (the patient having survived three months). It was probably a fracture *avec engrêlure*—a crushing with mutual interpenetration of the fragments. Whether during the progress of the case there was in addition an absorption of the osseous texture to any extent is doubtful. The cancellous structure was of natural closeness, firmness, and colour. Corresponding to the seat of the vertebral mischief the spinal cord showed unmistakable signs of much compression, its texture being flattened and translucent, the membranes at that point being unaltered; the cord below the seat of injury was apparently healthy; the membranes were normal, except the arachnoid of the cauda equina, which showed some diffuse redness. A little bloody serum occupied the lower part of the spinal canal.

The anatomical conditions revealed by the autopsy indicate pretty clearly the trivial prospect of advantage to be expected from operative interference in cases of spinal injuries, even where the external local signs might, *prima facie*, be held to justify the attempt at rectification of displaced bone.

The primary injury in such cases (as emphatically in the present one), is usually not restricted to a local compression of the cord, but involves also such a molecular disturbance of its structure as appears to be propagated throughout the entire segment of the organ inferior to the seat of direct mischief. This view is clearly signified, as it appears to me, in the present case, by the total absence of reflex movements in the lower limb, and also of *rigor mortis* in the same quarter. Mere local circumscribed injury on the contrary, should, on analogical grounds derived from experimental physiology, have involved an opposite state of things.

The symptomatic results of simple concussion of the &c., in "an excito-motory circle" is erroneous—that the act is that of the bladder alone, and that it is purely voluntary. This view at once simplifies the theory both of retention and of incontinence after spinal injuries. In spinal diseases where the patient survives for months (and the same obtains in disease of the vertebræ followed by permanent incontinence, the local disease having meanwhile undergone cure) the involuntary discharge is observed to take place at progressively longer intervals, until it finally assumes a truly periodic character, though still maintaining its involuntary nature. Inconvenience is averted in such cases by the preliminary warnings of sensation.

cord, unattended by changes visible on dissection, are also wholly in conformity with the above hypothesis.

In the case now presented, the condition of the urinary organs was of interest. The kidney structure showed nothing remarkable; the moisture which smeared the calyces possessed an *acid reaction*, whilst the mucous membrane of the bladder was neutral. The bladder was empty and quite contracted—its muscular coat perhaps a little thicker than natural; the interior of the organ was highly fasciculated; the mucous coat lining the prominences being of a dark purple colour; a couple of small circular ulcers were visible, and a smooth greyish white tract, of the size of a shilling, appeared to be the result of a cicatrized ulceration. No "viscid mucus" was to be seen, but a narrow rope of curdy pus lay on the membrane. The prostatic urethra was reddened.

The ulcerated condition of the mucous membrane in this and similar cases, generally but I think very erroneously referred to a different source, seems simply due to the morbid condition of the urine which obtains in such cases. The cause of the alkaline condition of the urine in spinal injury I believe to be wholly misunderstood, and to be traceable, for reasons which I hope shortly to assign, to a catalytic agency exercised by the mucous membrane itself, unaided by the (fabulous) "alcaline mucus," which is not secreted, and which (in the shape of ammoniated viscid pus) is the consequence and not the cause of the altered quality of the urine.

ABSORPTION OF THE CRANIUM BY A SMALL SEBACEOUS KYST.

Dr. FLEMING said that since the commencement of the session the subject of encysted tumours of the scalp had been brought under the notice of the Society, and particularly as to the situation of the tumour and its possible effect on the skull. He had an opportunity of removing one of those tumours that morning from a man advanced in life, who had had the tumour more than twenty years. He was in hospital for another complaint, and, seeing the tumour, he removed it. He would be happy to show the patient to any gentleman who wanted to satisfy himself as to whether tumours of this kind ever caused an indentation of the skull. They would find in this case a distinct cavity in the skull, corresponding to that portion of the tumour which was bound down *in situ*. He had not opened the cyst yet, but had no doubt its contents would be found to be those of an ordinary atheromatous tumour. He merely brought the specimen before them, and begged to repeat that there were cases in which these tumours, distinctly atheromatous, caused, from the length of time they existed, an indentation of the skull. There could be no doubt but that this tumour was quite superficial to the periosteum and pericranium.

CASE OF SEPARATION OF THE SYMPHYSIS PUBIS, WITH RUPTURE OF THE BLADDER.

Mr. SYMES said that on Monday, the 12th of February, a man, aged 45 years, fell from the roof of a new chapel, which was being built at Monkstown, a height of forty or fifty feet, and in falling he tumbled across some timber—scaffolding poles, which were projecting from the walls. He (Mr. Symes) did not see the man until eight days after the accident, as he was not brought into hospital until the 20th. His condition was then most lamentable. He was suffering from great desire and inability to pass water, and on examining him he found a large tumour occupying the hypogastrium, and reaching up towards the umbilicus. It was something like a distended bladder, differing, however, from a distended bladder in not being symmetrical, there being more of it on the right side than on the left. On examining the tumour, he could trace it into the pelvis on the left side, and on the right as far forwards as Poupert's ligament. There was extensive ecchymosis, extending from the right ilial spine down to the pubis; there was also an ecchymosis in the perinæum, but he experienced no uneasiness in this situation, and made no complaint when pressure was made there. He kept his

thigh semiflexed on the abdomen, and looked with horror on any movement of the limb, so much so, that he was induced to examine him for dislocation of the hip-joint, but found that there was no such lesion; some of his ribs were injured. Just before he (Mr. Symes) saw him the resident pupil had passed a catheter and drawn off three or four ounces of urine. He (Mr. Symes) then passed the instrument, and succeeded, after a great deal of trouble, in drawing off about two ounces of very fetid urine—a mixture of blood, pus, and urine. The operation occupied about three-quarters of an hour, as he had frequently to clean the eye of the catheter from the clots which filled it and obstructed the passage of the fluid. The urine came out dribbling, at uncertain times, and generally when least expected. This was followed by no sign of diminution of the tumour. The patient got a large allowance of wine, the usual opiates were administered, and he experienced some slight relief. He would not allow the catheter to remain in the bladder, so it had to be introduced every four hours. He died on Saturday, the 24th, exactly twelve days after the injury. On the day before his death he could trace a distinctly fluctuating tumour over the right side of the pubis. At the post-mortem examination, on cutting through the abdominal muscles above the pubis there was found a mass of putrescence. On getting into the abdominal cavity a great quantity of fetid urine and blood was met with, enclosed, as it were, in a sort of cyst formed of exuded lymph. This fluid had dissected its way between the peritoneum and the bones. It did not descend into the recto-vesical cul de sac. The amount of fluid was considerable, being over a quart. The intestines were matted together in the immediate neighbourhood, and a portion lay in front of the collection of matter, but the small extent of local peritonitis which was caused under these circumstances was remarkable. On examining the bones of the pelvis there was found a wide separation, even to the extent of three-quarters of an inch. At the symphysis pubis the inter-articular cartilage had all gone with the left side, the bone being quite bare on the right side. The right os pubis was about half an inch below the level of the left; the sub-pubic ligament and attachment of the triangular fascia had been torn through—this evidently accounted for the great ease with which the catheter could be passed into the bladder. On examining the right sacro-iliac synchondrosis, a patch of effused blood was found beneath the muscles in the neighbourhood; the joint was very movable, a great portion of the anterior ligament having been ruptured. On next directing attention to the bladder, two small rents were found in front, just above the level of the pubis, where the bladder is not covered by peritoneum. Mr. Symes said that a good deal of attention had been lately drawn to the subject of separation of the symphysis pubis with rupture of the bladder. Mr. Fleming, Mr. Hutchinson of London, and Mr. Hamilton, in his splendid work on fractures, had collected several instances. This case was remarkable for the small amount of local peritonitis, and for the length of time he lived (twelve days) after receipt of the injury.

ASCARIS LUMBRICOIDES IN THE TRACHEA.

Mr. SMYLY said the specimen which he was about to show to the Society was a very rare one. On that day three weeks a child, three years old, was admitted to the Meath Hospital suffering from great difficulty of breathing. It had been playing about the room while its parents and other members of the family were at dinner. The mother left the room for a few minutes, and when she came back the child was choking. Some one in the room said it had been eating cake, and that a portion of it had stuck in the throat. It was brought to some medical man in the neighbourhood, who endeavoured to push down the piece of cake with a probang. Failing in this the child was brought into the Meath Hospital, and the resident pupil sent for. When he (Mr. Smyly) came he found the child almost breathing its last, gasping, with scarcely any pulse at the wrist, and the heart very feeble indeed. He at once forced

the mouth open and introduced his finger. The first thing he discovered was a large mass of something which he took to be œdema. It was very soft, and by pressing his finger through it, it went down, as one would expect it to do were œdema present, and he felt the epiglottis and the vocal cords. He at once sent for his colleagues and went to get an instrument to perform tracheotomy. When he came back the child had ceased to breathe. There was no pulse whatever at the wrist, and the heart was only beating occasionally. He then got one of the late Dr. Hutton's catheters (No. 12), and introduced it into the larynx, and forced it between the vocal cords. The catheter probably went down to the bifurcation. He then put his mouth to the catheter and his hands to the child's breast, and began to perform artificial respiration by expanding the chest with his mouth and then pressing out the air. In twenty minutes the child gave a gasp. This encouraged him to go on, and after performing artificial respiration in this way from three-quarters of an hour to an hour the child breathed freely through the catheter. The pulse returned as soon as the child began to breathe, and the heart's action became very strong. Professor Macnamara examined the chest several times during this operation with the stethoscope, and discovered that respiration gradually returned in the upper portions of the thorax. He then had a consultation with his colleagues, and it was determined to perform the operation of laryngotomy. The tube was introduced and respiration fully established through it. The child went on for three hours very well. The operation was performed at ten o'clock, and at three in the morning it was breathing through the tube, very tranquil, reaction fully set in, and doing well in every way. Half an hour or so after he left convulsions set in. These increased in number and violence till eight o'clock on the following morning, when the periods gradually became longer, and the violence of the convulsions greatly decreased until five or six in the afternoon, when an interval of an hour elapsed between each attack of convulsion. The convulsions entirely ceased at four o'clock, the pulse began to fail, and about six o'clock in the morning the child breathed its last. On next morning (Monday) the post-mortem examination was performed. They were very much astonished to find a mass of worms which completely filled the pharynx. There were fourteen pieces. Dr. Barker examined them, and said they were the *ascaris lumbricoides*.

There were six complete worms, which were cut in the process of removal. The trachea and œsophagus were removed together. On laying open the œsophagus he found the head of a worm protruding through the larynx, and on making an incision from the opening where the operation was performed, he found a large worm doubled on itself, the loop lying exactly at the bifurcation. The two drawings which he exhibited, made by Mr. Lewis's artist, Mr. Burnside, gave an accurate idea of the appearances presented. The idea of tubing the larynx was suggested to him a year and a half ago by his friend, Dr. O'Flaherty, Deputy Inspector General. The description of tubing the larynx would be found in the volume of the *Journal of Practical Medicine* for 1858, in which a case was recorded where Mr. Buchert tubed the larynx very successfully. Dr. Barker, Dr. Wright, and some others of his friends had examined the authorities on the subject, and he believed there was only one case on record of a lumbricus being found in this situation. This would be found in the *Boston Medical Journal*, vol. lxvi., page 392.

FOREIGN BODY ON THE CORNEA.

Mr. COLLIS said that on Wednesday last, as he was leaving the Hospital, a boy came in stating that he had been using solder, and that from some cause or the other, this jumped into his face in a state of fusion. His whole face was marked with it. He complained that it struck him in the eye, and on opening the lids he (Mr. Collis) found that not only was there a good deal of solder impacted in the hair of the eyelids, but there was a small

portion lying in the cornea, and moulded to the form of the cornea, which had been thrown into the eye in a state of fusion. He thought the specimen presented sufficient interest to justify him in bringing it before the Society. The boy refused to remain in hospital, so that he was unable to speak as to the present condition of the eye, but when he saw it the eye was merely suffused; the conjunctiva of the lids were very much injected, but there did not appear to be any actual injury to the cornea.

LARYNGEAL POLYPI.

Mr. SMYLY showed a number of polypi which he had removed from the larynx of a patient at several sittings, and also the forceps (Dr. Mackenzie's) with which they had been taken away. He also showed a new mode of fixing the larynx and holding the laryngeal mirror with the same hand so as to leave the other free to operate with.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY,

Dr. MOIR in the Chair.

The sixth meeting of the 45th series of the Medico-Chirurgical Society was held in their Hall, 117, George-street, at eight p.m.

Dr. HANDSIDE read a communication from Dr. Vartan, of Nazareth, detailing an account of an amputation performed by him on account of elephantiasis of the leg, and in which acropressure had been successfully employed. The President, Dr. Watson, Dr. A. Wood, Mr. Annandale, and Mr. Benjamin Bell, took part in the discussion which followed, and which turned chiefly upon the merits of acropressure.

Dr. JOHN DUNCAN then read a paper upon the Galvano Puncture of Aneurisms. Two cases were related, one of which was completely successful, while in the other—an aneurism of the aorta—death was at all events delayed, and the result, so far as the coagulation of the blood was concerned, was all that could be desired. Dr. Duncan mentioned that 60 cases of aneurism had been treated by this method, and of these 27 were cured.

Dr. MATHEWS DUNCAN then read a paper upon Pelvic Serous Cysts following Puerperal Inflammation. Dr. Duncan gave the details of four cases which he had met with, all of which had been treated successfully. No similar cases, so far as he knew, had been hitherto recorded; he therefore believed them to be of great rarity and interest.

Hospital Reports.

CITY OF DUBLIN HOSPITAL.

Reported by Dr. BELCHER.

(Under the care of Mr. TUFNELL).

FRACTURE OF FEMUR TREATED WITH STRAW SPLINTS, IN A CHILD PREVIOUSLY THE SUBJECT OF DISEASED KNEE-JOINT WITH ANGULAR ANCHYLOSIS.

Case 1.—Anne Carroll, ætatis 10, resident in Dublin, was admitted into the City of Dublin Hospital on the 3rd of February, 1866.

Previous to admission she had suffered from general scrofula, as evidenced by various signs of the strumous diathesis; she had anchylosis, with effusion into the left knee-joint; displacement of the patella outwards, and eversion of the foot. The left limb was three inches shorter than the right. The immediate object of her reception to hospital was the occurrence of an oblique fracture of the femur three inches above the condyle at the date of her admission.

The limb was temporarily set and put upon the ordinary wooden splints; but on the following day Mr. Tufnell

had them removed, and straw splints substituted for them, and their use continued.

On the 3rd of March I saw her after a month's treatment by this method. At the time of this visit the union had taken place.

The apparatus employed by Mr. Tufnell commends itself by its extreme simplicity of construction, as well as by the facility with which it may be adapted to fractures, and little liability to shifting when once applied to the limb. The splints may be readily constructed of any length and breadth required in practice. Some good wheaten straw is selected of the kind used for thatching. A linen or calico bag of the size of the proposed splint is filled with the straws, which are packed sufficiently close to give due support to the limb, and yet so loose as to enable the splint to be moulded to any shape, and to prevent undue pressure on any particular spot. The bag thus filled is sewed up, and the splints so made are bound to the affected part by three web straps, one end of each strap terminating in a buckle, the other in a zinc tongue, so as to make the passing through the buckle easy; no padding is required.

FRACTURE OF HUMERUS TREATED WITH STRAW SPLINTS.

Case 2.—A. B., ætatis 52, a native of Kildare, but for the last thirty-three years resident in Dublin, married, by occupation a lawyer's clerk, and a man of intemperate habits, fell down some steps on the evening of the 13th of February, 1866. At the time of his fall he was "after dinner," and had his left hand in his trousers pocket. In this position he missed a step and fell on the left shoulder, causing a transverse fracture of the humerus at its surgical neck. Almost immediately he was admitted to the City of Dublin Hospital, where he presented appearances of the fracture above noted. Slight shortening of the limb and great swelling were prominent signs in his case, with immense extravasation of blood. The limb was put up in the straw splints.

Two days after admission he had an attack of delirium tremens which was treated by the exhibition of the solution of hydrochlorate of morphia in alcoholic liquors, with good result.

During this attack he broke loose the apparatus and slashed about the broken limb in a violent manner, causing extensive extravasation all over his side, chest, and back.

From this, however, he recovered. When I saw him on the 3rd of March, Mr. Tufnell, in demonstrating the fact of union having taken place, pointed out to me the extensive injuries the man had inflicted on himself during the paroxysms of delirium tremens, and at the same time he remarked that the remains of the extravasation were complicated with the remains of what had been aggravated and extended psoriasis. He was then doing very well.

I saw him a second time on the 15th of March, when I was informed that he was about to be discharged, so well has this case progressed under this plan of treatment.

FRACTURE OF BOTH BONES OF LEG TREATED WITH EGG AND FLOUR FIXED APPARATUS.

Case 3.—Joseph Thomas, ætatis 40, married, by occupation a cabdriver, a man of temperate habits, and in other respects healthy, was admitted to the City of Dublin Hospital on the 3rd of February, 1866, with a transverse fracture of both bones of the left leg, about two inches above the ankle-joint. This accident was caused on the day of his admission by the fall of a cart-wheel on his leg.

On admission the limb was set, and put up with McIntyre's splints. On the 5th of February, Mr. Tufnell removed these, and put the leg up in Gibbs' splints. Again, on the 13th, the latter were removed, and the limb was put up in the "egg and flour" fixed apparatus, three or four days after which change the patient was able to put his leg to ground.

I saw him on the 3rd of March, when Mr. Tufnell fully described this mode of treatment, and strongly argued its superiority to any other in cases of this kind. At this time the man could use his leg to some extent, of course with support; but the freedom from confinement, and the consequent advantage to the patient's health and spirits, were evident to all who saw him, as constituting some, but by no means all, the advantages of this plan of treatment. This plan, which I shall here term, "Tufnell's Plan for the Immediate Treatment of Fractures by Fixed Apparatus," was fully described by that gentleman in a lengthened essay in the *Dublin Quarterly Journal* for February, 1865, so that it would be out of place to repeat here what he has published at a former time. I may, however, remark that to make the splint itself, the practitioner only requires the white of eight eggs, and half a pound of flour for the fixing substance. "The main feature of difference between this mode of setting fractures and every other kind of fixed apparatus (writes Mr. Tufnell) is the construction of the splint in two halves, and the applying of the bandage which is to form the same, lengthwise, instead of circularly, thus avoiding all possible sources of constriction of the limb."

On the 15th March I again saw this case, which is as successful as any surgeon could wish a case to be.

Foreign Medical Literature.

DR. STOKES ON THE GENERAL TYPE OF DISEASE.

(Read at the Meeting of the Præstø Medical Society, on the 15th October, 1865.)

By G I E R S I N G.

Translated from the *Ugeskrift for Læger*, 20th Jan., 1866, (Copenhagen, 3rd series, 1, Nos. 4 and 5,) for
THE MEDICAL PRESS AND CIRCULAR.

By WILLIAM DANIEL MOORE, M.D. Dub., M.R.I.A.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS, OF THE NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

WHEN we last met at our respected President's, at Vemmetofte, I read before you a short essay, chiefly after Chauffard, upon the Stationary Fever, or the prevailing type of disease, which essay subsequently appeared in the "Ugeskrift for Læger," of the 2nd September. It was there shown how Sydenham, and subsequently Stoll, contended for the proposition, that the acute diseases, fevers in the wider sense, which in the main preserve their type unaltered for long periods, are nevertheless subject to unknown influences and operations, which produce a variation in their general character, for example, with respect to the strength or want of strength, with which all the morbid phenomena, all the morbid action, both local and general, proceed in the system. When I, for example, speak of strength and want of strength in the morbid development, I do so for this reason, that this is the only direction in which we have in some measure distinctly recognized this vibration or change, while with Dr. Chauffard we certainly have good reason to assume that there are other respects in which this change proceeds, that it is not only, if I may so speak, quantitative, but also qualitative, and that in the course of time there will consequently be other characters to discover for the prevailing type of disease than the sthenic or asthenic.

Much as there is, at least in my opinion, in favour of the correctness of this doctrine of such an alternation between sthenia and asthenia, there are many medical men who regard it all as an illusion, and so long as these have such leaders as, for example, Prof. Bennett, Dr. Markham, &c., we must of necessity look upon the question as doubtful and open. I therefore believe that I have good reason

again, to-day, to request your attention to a fresh contribution in respect to this matter—a contribution which must have equal weight, whether we look to the personality of the witness, or to his testimony itself.

At the annual meeting of the British Medical Association, held in the month of August last, the well-known Dublin professor, Wm. Stokes, delivered an address, which treated chiefly of the general type of disease, or as Sydenham called it, the "constitutio morborum stationaria," and the change which this has undergone during the last thirty or forty years. The part of his address which relates to this question I shall now take the liberty of communicating.

[The author then translates, with some omissions, Dr. Stokes' address from the words:—"Medicine, in its great quality as a practical art, advances in many directions;" to the end of the quotation from Dr. Watson, closing with the words, "and that we are at present living in one of its adynamic phases."]

The foregoing is, gentlemen, in the main, what Stokes in his address stated in defence of the opinion, that there really is a varying predominant morbid type, which impresses its stamp upon all acute diseases, and which is therefore of the greatest importance to us practical physicians, if we will treat our patients aright. According to the testimony advanced, it is evident that the change or revolution does not occur in all places at the same time, just as the period which elapses in the different localities, before the revolution is very well marked or attains its acme, is also certainly very different. There can thus be no doubt that the change in our days began earlier in Ireland than in Scotland and in England, and in the latter countries earlier than on the European continent, at all events than in France and here in Denmark. As to fevers, whether continued, remittent, or intermittent; or exanthematous or rheumatic; I do not remember that they, with the exception of the rheumatic, have for the last thirty years been treated strictly antiphlogistically, with copious evacuations of blood, &c. Fevers I may therefore leave out of the question; but with respect to inflammations, it is not, in my opinion, more than about ten years since we have seen the revolution very evidently take place; although it may be about twenty years since it began, while it is forty years since it was traced in Ireland, where it seems to have proceeded more rapidly than with us, so that the date has there been capable of more definite demonstration.

If we take pneumonia as our starting point, because of the local inflammations, it was in the treatment of this disease that the dispensability of antiphlogosis or evacuations of blood was first observed; it is not more than fifteen years since practitioners began in this country to employ such means more sparingly, and from this date we may therefore reckon that the type of the disease here began to pass from sthenia into asthenia. The change, however, did not proceed so very rapidly, and the asthenia has not as yet reached so great a pitch; that there can be reason to suppose that it has attained its acme, so that it will probably be long before the pendulum will again begin to vibrate backwards.

But with all this the change is not quite unmixed or universal. What we lately heard from Stokes, that in the epidemic of 1826-28 in Ireland cases occasionally occurred among the asthenic forms of pneumonia, where the inflammatory development proceeded so briskly that the old antiphlogistic means in their whole extent were fully indicated, is repeated here also among us, and we should therefore be very careful not to let the recognition of the prevailing asthenia make us too secure, or render our treatment too mechanical. To wish, for example, to fix a certain limit of age, beyond which venesection in pneumonia is absolutely to be rejected; to despise him who bleeds a sexagenarian pneumonist, evinces but little practical sense.

It is, however, certain that the development among us

still proceeds steadily in the direction of asthenia, and that the cases of pneumonia in which there is reason to take blood are becoming rarer and rarer; but it cannot be sufficiently insisted on, that the reason of this is not to be sought in the hypothesis, that one well-known physician or another has made a new, unparalleled discovery; that we have hitherto treated inflammations quite erroneously; that evacuations of blood are, and always have been, bad and unsuitable means, which will never find reasonable employment in the treatment of this disease; but simply in the fact that pneumonia, like other inflammations, presents, under the influence of an altered general type of disease, another character than formerly, and therefore requires for its cure other remedies than it did when the type of disease was different.

When Stokes and Christison inform us that they observed, before the revolution took place, that the pulse in fever was hard and incompressible, this appears to me not to have been with us so completely the case. Where the inflammation, for example, in pneumonia was violent and the dyspnoea was great, the pulse was often felt to be small, and for intelligible reasons it did not rise until after sufficient evacuation of blood, when improvement set in. The pulse consequently need not always be tense and hard to justify venesection.

But that the asthenia has not here as yet attained the height it has reached in England may be inferred from the fact that, so far as I am aware, it has not been found necessary to use such strong stimulants as brandy, &c., to maintain the sinking powers—means which seem in the English hospitals to find frequent employment. Even should we yet come so far, we have still much to go through.

As I have already said, it is probable that it is not only the quantity of the diseases, but also their quality, which is modified by the general morbid type; not merely the strength of the reaction, but also its species and external form, which change under its influence. If this be so, the frequency or rarity with which the several forms of disease occur at different times, as also the seat and nature of the morbid localisations, will find their cause and explanation in the peculiarity of the predominant morbid type.

Thus, since the present type of disease has fairly taken root here, it seems to me that it is rare to meet with inflammations in the serous membranes, and still rarer to find such inflammations develop themselves with any internal strength. A pure pleuritis, which formerly occurred, comparatively speaking, rather frequently, has for the last six or eight years been a great rarity, and even where it occurs in combination with pneumonia, it is of minor importance. I speak of course of my own experience. Now, how far the stationary fever has an actual influence upon the more frequent or rarer occurrence of this or other diseases may appear differently, accordingly as we have our attention directed to the point; but it is unlikely that it is without such an influence. Thus it seems to me probable that diphtheria must thrive best during the prevalence of asthenia, while croupy laryngitis must at the same time be rarer; that phlegmonous erysipelas is now among the rarities, and so with many other diseases. In this direction there is certainly still much obscurity, which waits to be cleared up by future observations and investigations; but it would undoubtedly be both interesting and instructive, if some practically educated physician, who was not attached to any preconceived opinion, and who had access to the hospital archives, would go through these and give a sketch of the changes and variations which have occurred in the treatment of acute disease in the last five decennial periods. In this way much, which now depends more or less on individual views, would assume a vastly more definite form, at least so far as the metropolis is concerned; and when this should be supplemented by the definite experience of individual physicians—and such might be obtained,—from the different districts of the country, it would be possible to get a somewhat correct picture of the development of the general type of disease in this kingdom, which is at present entirely wanting.

ABSTRACT OF
METEOROLOGICAL AND MEDICAL OBSERVATIONS
TAKEN AT THE MILITARY
HOSPITAL, NICE,

FROM THE 20TH FEBRUARY TO 2ND MARCH, 1866.

By Dr. CABROL,

CHIEF PHYSICIAN TO THE HOSPITAL.

Translated by R. CROTHERS, M.D., Nice.

THE atmospheric pressure which was at 0.758, with slight showers, at the beginning of this decade, rose to 0.763 on some fine days in the midst, and again fell to 0.748 at the commencement of the rain, which has now continued for some days. The rainfall amounted to 15 millimetres on the 27th February, and 20 millimetres on the 1st March; total to the present 49 millimetres. Under its influence the waters of the Paillon and other streams* have been disturbed without being sensibly increased. The soil is soft and the air humid. The temperature has risen to 86 in the sun, but only on the fine days in the midst of this decade; to-day it is only 50. The lowest temperature has been 37 in the night.

The winds which blew with some force from the east during the first days, have become almost insensible; nevertheless, since the advent of the rains the sea has been rough, sometimes even stormy; snow is visible on the distant summits of the Alps, but there is not a trace of it in the lower grounds, neither in the air nor upon the soil. The appearance of snow coincides with last year, for the papers of the 22nd February, 1865, mention it as covering the ground in the neighbourhood of Lyons and other parts of France as at present.

In diseases there is not anything to be remarked attributable to the action of the climate, except some trifling ailments. Chronic diseases are favourably modified and progressing without any unusual complications, the sanitary state being very satisfactory.

FROM 1ST TO 10TH MARCH, 1866.

The rain (as noticed in our last bulletin) continued and even increased during the first days of the month, so that whilst the rain-gauge marked only 15 millimetres of rain on the 27th February, it indicated 20 on the 1st March, 36 millimetres on the 2nd, and 25 millimetres on the 3rd March. There has fallen upon Nice more than 1 decimetre (4 inches) of water in almost continuous rain.

On the 1st March the waters of the Paillon were slightly increased and discoloured. This volume and discoloration rapidly augmented, and on the 3rd its bed (so often dry) was entirely covered by its yellowish turbid waters. This rapid torrent running out to sea, coloured the latter to a considerable distance in the direction of Villa-Franca. At the same time a similar discoloration was visible in the south-west, caused by the waters of the Var. The sudden transformation of the Paillon into a rapid torrent is accounted for by the height and steepness of the mountains amongst which it rises. The waters falling upon them soon penetrates the slight covering of earth, and comes immediately into contact with strata of impermeable rock, upon which it quickly flows down into the bed of the river.

During these heavy rains the barometer fell to 0.743 (29 3-10ths); it then rose a little, and has oscillated between 0.749 and 0.755 (29 5-10ths and 29 8-10ths), indicating changeable weather. The temperature has been generally low, the mean being only 50. The lowest during the night 38; during the day it has several times risen to 77 in the sun. The sea has been constantly agitated, although at times there has been scarcely any wind. This agitation was very great on the nights of the

* The Paillon is a stream which rises in the mountains a few miles north of Nice, divides the Old and New Town, and empties itself into the sea between the Boulevard du Midi and Promenade des Anglais.—R. C.

5th and 8th, also on the day of the 9th, when the waves rolled in with great violence, dashing over the rocks, even upon the road, under the Castle hill. *En resume*, this period of the first ten days of March has been characterised by the variations and sudden changes of the atmosphere. This variability constitutes one of the characters of the season, and is not infrequent at this period of the year. These changes have been rather disagreeable than hurtful; the most irritating and injurious has been the period of north-west wind (the mistral*), which blew most unpleasantly on the night of the 7th. At the same time, this wind, fortunately not very frequent here, is very considerably modified in its passage from Provence by the chain of the Etrilli mountains.

In noticing these various atmospheric changes, it should be observed that they have not been so violent in Nice as in other places.

The vegetation here has not suffered. Persons in good health have only experienced slight inconvenience, and invalids themselves, although feeling these changes, have not suffered any serious attacks of illness from them.

They have experienced only slight irritations of various kinds—neuralgias, returns of preëxisting rheumatic pains, sleeplessness, feeling of painful weariness, and nervous symptoms differing with the different diseases. This unsettled weather (always of short duration at Nice) has not given rise to any new forms of disease, neither has it left anything serious as the result. In some diseases their serious symptoms should not be imputed to the climate, and in many it has produced very decided amelioration. The sanitary state of Nice is satisfactory.

THE GUTTA-PERCHA SHOE IN THE TREATMENT OF TALIPES.

By ALFRED C. POST, M.D.,

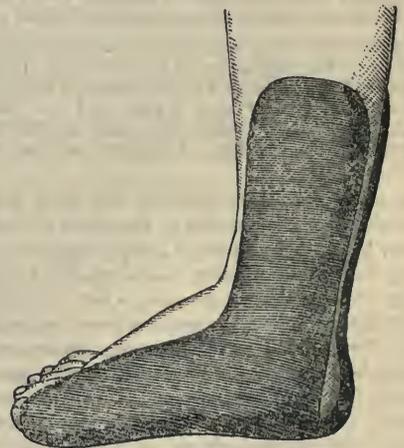

PROFESSOR OF PRINCIPLES AND PRACTICE OF SURGERY, UNIVERSITY MEDICAL COLLEGE, N. Y.

ABOUT sixteen years ago I was treating a little girl for talipes varus, with a modification of Scarpa's shoes, which I was then in the habit of employing, when troublesome ulceration of the integument occurred from the pressure of the straps which were used to secure the shoes upon the feet. It was evidently a matter of necessity to omit for a time the use of the shoes, until the ulcerated surfaces should have an opportunity to heal. I was much chagrined by the prospect of a long delay in the treatment, especially as the patient resided in the country, and it was quite inconvenient to the parents to keep her for a long time in the city. I was led to reflect on the best means of preventing a return of the deformity towards its original condition, during the period when I should be obliged to suspend the use of Scarpa's shoes. It occurred to me that a splint or shoe of gutta-percha might be applied in such a manner as to maintain the improvement which had already been gained by the treatment, if not to make some further advance towards the cure of the deformity. I accordingly contrived and applied such an instrument, keeping it in place by means of a roller bandage. I found that by this means the feet could be maintained in a good position, with very little inconvenience to the little patient; and under appropriate dressings, the ulcerated surfaces soon healed. To my surprise, the deformity yielded more readily to the new treatment than it had done while Scarpa's shoes had been worn, and I felt no disposition to return to the use of the spring shoes after the ulcers had healed. From my experience of the benefits of the simple contrivance which I had used in the case just alluded to, I was induced to employ it in similar cases which were presented to me; and the results were so entirely satisfac-

* The mistral is a cold, dry, north-west wind, which often blows with violence in the valley of the Rhone and on the coast of Provence; but it is deflected from its direct course and its violence very much diminished by the mountains beyond Cannes, and arrives at Nice rather as a west wind. There are some quarters here almost completely sheltered from it.

tory, that I have ever since employed shoes or splints of similar construction in the treatment of infantile club foot, in preference to the spring shoes which surgeons ordinarily employ for the same purpose. The material which I ordinarily use in the construction of these shoes is a gutta-percha sheet from a sixteenth to an eighth of an inch in thickness. It is cut of such a shape as to adapt itself to the sole and sides of the foot, leaving a space uncovered on the dorsum of the foot equal to about one-third of the breadth of the foot; it is also adapted to the sides of the leg, extending up two-thirds of the distance to the knee, and leaving a narrow space uncovered before and behind, each space so uncovered being about one-sixth of the circumference of the leg. The material is readily moulded to the shape of the limb, by immersing it for a few seconds in water, at a temperature of 100° Fahrenheit. I am in the habit of moulding the shoes thus heated, over a wooden last made for the purpose. The last is not made after the fashion of a bootmaker's last, but it is shaped like the natural leg and foot, except that the outer side of the foot is made to correspond with the inner, thus obviating the necessity of having separate lasts for the right and left foot. I have sometimes used similar shoes made of felt stiffened with shellac, as manufactured by Dr. Ahl, of Southern Pennsylvania. In order to mould the felt, it must be dipped in water at nearly a boiling temperature, and the hands require to be protected by means of cotton gloves wet with cold water. I am rather inclined to prefer the gutta-percha shoes to those which are made of felt, especially as the former material is more conveniently moulded to its proper shape.

I generally commence the treatment of infantile club foot by the subcutaneous division of the tendo-Achillis, after which I apply a strip of isinglass plaster over the small wound of the skin. I then have the foot held by an assistant as nearly as possible in its normal position, and while it is so held, I carefully apply a roller bandage so as to cover the foot and leg, beginning the application on the outer side of the ankle. I then apply the gutta-percha shoe, an assistant grasping the leg with one hand pressing the upper part of the shoe against the sides of the limb, and with the other hand pressing the sole of the shoe against the sole of the foot. While the shoe is thus firmly pressed against the leg and foot, I apply a roller bandage firmly, so as to secure it in its place. After the lapse of twenty-four to forty-eight hours, I take off the bandages and shoe, wash the foot, wipe it dry, use passive motion freely in different directions, and then reapply the apparatus as before. The application is repeated at intervals of two or three days, until the

foot is brought to its proper shape, when it is put up in a laced boot, lacing to the toes, and having a firm sole and stiff sides, provided with iron braces which extend

nearly as high as the knee, and secured by a strap and buckle around the upper part of the leg.

The following are, in my estimation, the advantages of the gutta-percha shoe over Scarpa's shoe, and its various modifications:—

1st. Its greater simplicity, and the ease with which it is made. When the material is at hand, the shoe can readily be made in fifteen minutes.

2nd. It is much cheaper than the spring shoe.

3rd. It is more comfortable to the patient, being lighter, exerting a less injurious pressure, and being less likely to be kicked off by a restless child.

4th. It is much less likely to occasion excoriation or ulceration of the integuments.

5th. It expedites the cure, giving a better support to the foot, and bringing it more readily into its normal position.

The annexed woodcut exhibits a view of the gutta-percha shoe, and of the last on which it is moulded.—
Richmond Medical Record.

Reviews.

THE PRINCIPLES AND PRACTICE OF MEDICAL JURISPRUDENCE. By ALFRED SWAYNE TAYLOR, M.D., F.R.S., Fellow of the Royal College of Physicians, and Professor of Medical Jurisprudence and Chemistry in Guy's Hospital. London: Churchill and Sons. Pp. 1166. 1865.

WHAT medical practitioner or assize crown lawyer is not acquainted with Taylor's "Medical Jurisprudence?"—a work which has reached an eighth edition, and whose author has a world-wide reputation, little needs the reviewer's comments. But to pass over, in a casual manner, a book of such importance, would neither be polite to the author, nor at the same time would we consult the interests of our readers by pursuing such a course, especially as the subjects treated of in a work on Medical Jurisprudence are of so multifarious a nature, and of such public interest, that the medical man who would be unacquainted with the latest phases of the various subjects referred to might risk his professional reputation.

We presume there is scarcely one of our readers who is not in possession of a copy of some one of the previous editions of this work, and therefore we need not recapitulate the chapter of contents; but as the present edition contains so large an amount of additional matter, we give the following extract from the author's preface, which briefly details the difference between the present and former editions:—

"Among the new subjects which find a place in this volume are—The Signs and Phenomena of Death, with an account of the Changes which take place in the Dead Body; Putrefaction in Air and Water, and its conditions; the Identity of Bones, Skeletons, and Mutilated Remains; Spontaneous Combustion; Life Insurance and Medical Evidence."

In addition to these subjects new facts and cases have been added to every section of the work, the greater part of which have been re-written; engravings have been introduced into those chapters which admitted of illustration; under the subject of poisoning, the crystalline form of mineral and organic poisons have been engraved from specimens observed with the microscope; the leaves and seeds of poisonous plants are also represented, the leaves being engraved from photographic copies of the natural leaves, showing their complete form and structure, and the seeds of the natural size and shape, as well as magnified; under wounds, illustrations of the principal organs and cavities are given, so as to render the description of wounds by medical witnesses more intelligible to members of the legal profession; other subjects, which it is here unnecessary to specify, will also be found to have their appropriate illustrations.

The preliminary chapter on medical evidence contains such a mass of deeply-interesting matter, that the careful study of it will amply repay the most experienced practitioner; and at the same time, for the junior members of the medical profession it contains advice of such paramount importance to them, that its contents should be engraven on their memory.

The following extracts may serve to illustrate the correctness of our statement. After the definition of the science of medical jurisprudence, the author states—

"The purpose of this work has been to bring, as far as possible, within a reasonable compass, those subjects which especially demand inquiry, and which more particularly concern the duties of the educated physician and surgeon."

The definition above given necessarily implies that a medical jurist should have a theoretical and practical knowledge of all branches of the profession, a large experience, and the rare power of adapting his knowledge and experience to emergencies. He should be able to elucidate any difficult medico-legal question which may arise, and be prepared at all times to make a cautious selection of such medical facts, and a proper application of such medical principles, as may be necessary to enable a judge to place the subject in an intelligible light before the jury, and to enable a jury to arrive at a just conclusion. Again—The records of our law courts contain many unfortunate exposures, which might have been easily avoided had the witnesses only availed themselves of the opportunities afforded to them of acquiring a knowledge of the subject; but they had unreflectingly acted on the principle that medical jurisprudence was a dry, dull, and useless study, and that the practice of it was remote and speculative. This feeling is, however, fast disappearing. Those who have been compelled by circumstances to give their attention to it, have in subsequent cases taken care to prepare themselves for the ordeal through which every medical witness must pass.

On medical witnesses, the author says:—

"A man who goes to testify to the truth to the best of his ability should bear in mind two points. 1. That he should be well prepared on all parts of the subject on which he is about to give evidence. Let him remember on these occasions the advice contained in the Latin motto—*Ne tentes aut peripice.*" 2. That his demeanour should be that of an educated man, and suited to the serious occasion on which he appears, even although he may feel himself provoked or irritated by the course of examination adopted. A medical witness must not show a testy disposition in having his professional qualifications, his experience, his means of knowledge, or the grounds for his opinions very closely investigated; he should rather prepare himself to meet with good humour the attempts of an adverse counsel to involve him in contradiction, and show by his answers that he has only a desire to state the truth."

Respecting quotations from books:—

"It is a not unimportant custom with counsel to refer to medical works during the examination of a witness. He is expected to have a fair knowledge of the writings of professional men in reference to the subject of inquiry. The authority is mentioned, the passage is quoted, and the witness may be then asked whether he agrees with the views of the author, or whether he differs, and if so, his reasons."

On medical reports for inquests, in reference to technical terms, the author states:—

"Putting aside those cases in which a medical man thinks he is displaying his erudition by the selection of such terms, there can be no doubt that the greater number of medical practitioners fall into this practice from mere habit. They think they are addressing the report to the president and members of a medical society, instead of a coroner and jury who have never in their reading or experience met with such terms, and to whom therefore they are perfectly unintelligible. Setting aside the men who act as jurors, it may be observed that educated persons, such as coroners and magistrates, do not commonly include professional terms

within the range of their studies. There are but few of them who understand the difference between 'perineum' and 'peritoneum,' or the meaning of the words 'hemispheres of the brain,' 'pia mater,' 'puncta cruenta,' 'centrum ovale,' &c. On one occasion I heard a learned judge ask for an explanation of the meaning of the term 'alimentary canal.' A slight consideration will show to any medical practitioner that refined professional language is wholly misplaced in a report which is intended to inform and convince the minds of ordinary men upon plain matters of fact."

Our readers will be able to judge from these extracts the value of this chapter.

To enter into the merits of each chapter of this book would occupy more space than the present crowded state of our pages would permit of. We will, therefore, just make a selection from one or two more chapters, which will enable our readers to form a good criterion of the talent, experience, care, and close observation of our author, as well as the anxiety he has evinced to make the book represent the present state of our knowledge of the manifold subjects which are embraced under the title of "The Principles and Practice of Medical Jurisprudence."

The succeeding chapter relates to—

"Questions connected with the dead body—signs of death—cessation of respiration and circulation—apparent death—trance—coldness of the body—post-mortem calorificity—rigor mortis—cadaveric rigidity—circumstances which influence its commencement and duration—other indications of death."

Among the subjects which sometimes claim the attention of a medical jurist in reference to the bodies of persons found dead, are the conditions known as real and apparent death, the proofs of death, and the priority of death. A knowledge of the changes which take place in the dead body at a recent as well as a remote period, may be usefully applied to the determination either of the reality of death (a problem seldom involving difficulty) or of the period at which death took place—a question of considerable importance, and upon which the guilt or innocence of an accused person may depend.

Medical jurists have enumerated certain signs or indications of death. It will be necessary to consider these in the order in which they commonly present themselves to the observer:—

1st—Cessation of Respiration and Circulation.—The cessation of these two important functions is regarded as in itself sufficient to determine the reality of death; but persons have been resuscitated from a state of asphyxia, and others again have recovered from a state of lethargy or catalepsy, when to all appearance the respiratory and circulatory processes had been completely arrested. Life is certainly not incompatible with a temporary suspension of these two important functions; but, in making this admission, it is undeniable that the process must be speedily re-established, or death will assuredly follow."

The next chapter refers to—

"Cadaveric spasm—evidence of murder—suicide or accident furnished by the position of the dead body—muscular irritability—tests of its presence—post-mortem contractility—alleged premature interments—proofs of the reality of death—death trance—apparent death in the drowned and in new-born children."

In reference to persons found dead, the position or attitude of the body, if undisturbed, may often throw an important light on the mode of death, and on the question whether the deceased had died by his own act or by the act of another.

"*Cadaveric Spasm.*—It has been already stated that, as a general rule, the muscular system passes into a state of relaxation at the moment of death. This is observed in cases of tetanus of a severe form, whether produced by disease or by poison. Half a grain of strychnia was given to a rabbit; after several fits of convulsions the animal died; respiration ceased in twenty-three minutes. At this time there was perfect flaccidity of the body, limbs, and joints;

but this condition lasted but for a very short period. The animal was placed on its back and the legs raised for the purpose of making an examination of the chest. In ten minutes the body became, while still warm, perfectly rigid in the attitude in which it was held, the forelegs remaining stretched upwards and wide apart. If an animal dies in a convulsion and the body is not disturbed, the tetanic spasm may pass rapidly into cadaveric rigidity. This has been called tetanic rigidity; but it is, in fact, cadaveric rigidity or muscular spasm showing itself in a persistent form after death."

The next chapter treats of—

"Inference of the time of death from the state of the body before putrefaction—priority of death—presumption of suicide or murder—of survivorship—stages of change after death—cadaveric lividity—sugillation—ecchymosis."

The next chapter is a continuation of the subject, and refers to—

"Putrefaction—its nature and progress—production of gases—post-mortem hemorrhage—pressure on the viscera—nature of the gases of putrefaction—change in the colour of the skin and other organs—putrefaction in air—conditions for the process—circumstances which modify it—influence of disease and certain poisons—putrefaction of bodies buried in graves—production of adipocere—its chemical nature."

The sixth chapter is a very interesting and important one, and relates to:—

"Identity of mutilated remains—cases—exhumation of skeletons—human and animal bones—determination of sex, age, and personal peculiarities—determination of age by the teeth—questions of personal identity—evidence from fractures, disease, and deformity."

The seventh chapter is also one of great interest, and extends to a considerable length:—

"Causes of death—sudden death—syncope, asphyxia, coma—presumption of death—medical evidence of death in cases of several persons perishing from a common cause—presumption of survivorship."

"Medical jurisprudence takes cognizance of all violent causes of death, and is only indirectly involved in those cases of natural death which simulate the effects of violence. Thus all causes which operate to produce death suddenly, as by syncope, asphyxia, or coma, especially demand the attention of a medical jurist. These may be either natural or violent, and the distinction between them is of importance, since the guilt or innocence of a person charged with crime may depend on a correct determination of the cause. The continuance of life depends upon the proper and regulated action of the heart, lungs, and brain, and the inter-dependence of these organs is such, that the arrest of the functions of one of them is speedily followed by the arrest of the others; hence they have been called the tripod of life. When the suspension of the motions of the heart is the primary cause of death the person is said to die by syncope. The term asphyxia is applied to death which begins by the lungs, and coma to that which arises from a primary disturbance of the functions of the brain."

The chapter on wounds, which is one of deep interest to the country surgeon especially, who is so often brought into a court of justice to give evidence on these matters, and who would feel in a very awkward position in an assize court under the cross-examination of counsel (who had probably the day previous to the trial closely studied this same chapter) unless the medical witness was well acquainted with all the points for the defence which the ingenuity of the lawyer who conducts the case might suggest. This chapter extends over 220 pages, and although many of our readers might perceive a similarity in some of the details with what has appeared in the previous edition, yet the subject is so much amplified that it appears to wear quite a novel aspect. After giving both the surgical and legal definition of a wound, wounds dangerous to life, examination of wounds, description of wounds, examination of the dress, &c. &c., the following extract may serve as an illustration of the additional matter which has been given even in this single chapter:—

"This is sometimes a most important part of the duty of

a medical man. In a case of severe wounding of whatever kind, he should always require to see the dress of the wounded person; it may throw a material light on the mode in which a wound has been produced; it may remove an erroneous suspicion of murder, and may sometimes serve to indicate that a wound has been self-inflicted for the concealment of other crimes, or falsely to impute its infliction to other persons; marks of blood, dirt, grass, or other substances on the clothing may also throw a light upon the mode of infliction; so, again, the use of a weapon, in reference to cuts or stabs, may be inferred from the dress presenting corresponding cuts or perforations. The examination of the clothing in the Waterloo-bridge tragedy threw a light upon the question of murder. The over-coat presented in the collar behind and towards the left side a cut or a stab from a double-edged knife. The under-coat, as well as the waist-coat, presented the mark of a similar stab, corresponding in size, form, and direction to the cut in the collar of the over-coat. The shirt beneath was much stained with blood. The stab took a direction from above downwards, and must have penetrated into the chest. Its situation and direction precluded the idea of its having been self-inflicted, as there was no blood on the over-coat where cut, the weapon had not before been used for inflicting a wound, and the deceased had obviously been stabbed from behind with all his clothes upon him. The theory that this was not a murder would involve the assumption that the over-coat, under-coat, and waist-coat had been placed upon some lay figure for the purpose of imitating a fatal stab behind, and that the under-shirt had been covered with blood to add to the appearance. No reasonable motive could be assigned for such a proceeding."

We deem it unnecessary to make any further extracts, as we are sure from those we have given that our readers will be able to judge how far the present transcends the former edition. Indeed, this is no ordinary work; whether we consider the prodigious amount of labour bestowed on it, the diversity of talent displayed in its execution, the vast experience of the writer, the sound and accurate views which the author enunciates, one and all combine to rank the present volume as the British standard work on the Principles and Practice of Medical Jurisprudence. As the present age is essentially one of progress, and as its impress is indelibly stamped on every department of science and arts, so has the author kept pace with the spirit of the age, and the medical practitioner who rests satisfied with the information he has acquired in his earlier years, will find himself outstripped in the race by many of his junior brethren. We consider also that the members of both the legal and medical professions are under no small amount of obligation to our author for the careful digest of the evidence and legal points raised at the various trials connected with the subjects referred to in the work.

In conclusion, we would remind our readers of the vast importance to them of an intimate acquaintance with the latest aspect of each of the subjects which come within the province of the principles and practice of medical jurisprudence, as there are no means by which a medical practitioner may so easily mar his professional reputation as *even to seem* to be ignorant of the various bearings of the subject on which he may be called to give evidence in a court of justice, and at the same time none by which the educated surgeon or physician can give such public evidence of his professional attainments, and thus shed a lustre on his profession. More especially at the present time, when the medical profession seems destined to attain a higher status, is it needful that each member of the profession should feel as if on him alone rested the responsibility of advancing its onward progress.

We should not omit to mention that in every case the author is careful to state the various parties to whom he is indebted for his information; and among the number we find with pleasure the name of Dr. Geoghegan, the talented Professor of Medical Jurisprudence, of the Royal College of Surgeons in Ireland, very often referred to in the work.

Messrs. John Churchill and Sons being the publishers, it is almost needless to state that the paper, type, and engravings are excellent, and quite in accordance with the style for which they are so justly celebrated.

As a matter of course, this book must occupy a place in the library of every legal and medical practitioner who values his professional reputation.
